ARTS and SCIENCES.

HIBISCUS.

HIBISCUS, in *Botany*, ιβισκος, a Greek name, of unknown derivation, for the αλθαια of Theophraſtus, ſuppoſed to be the Marſh Mallow, or ſomething very near it; hence the word was choſen by Linnæus to deſignate a genus of that family, which had hitherto received only barbarous or ill-conſtructed appellations.—Linn. Gen. 356. Schreb. 468. Willd. Sp. Pl. v. 3. 806. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 454. Cavan. Diſc. faſc. 3. 143. Juſſ. 273. Lamarck. Illuſtr. t. 584. Gærtn. 134. (Ketmia; Tourn. t. 26.)—Claſs and order, *Monadelphia Polyandria.* Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth double; the outer permanent, of many linear, ſometimes ſpatulate, leaves, rarely united into one at their baſe; inner of one leaf, cup-ſhaped, either five-cleft half way down and permanent, or with five teeth only and deciduous. *Cor.* Petals five, roundiſh-oblong, narroweſt at the baſe, ſpreading, attached below to the tube of the ſtamens. *Stam.* Filaments numerous, connected in their lower part into a tube, in whoſe upper part, both at its ſummit and ſides, they become ſeparate and lax; anthers kidney-ſhaped. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, longer than the ſtamens, five-cleft in its upper part; ſtigmas five, capitate. *Peric.* Capſule of five cells and five valves; the partitions double, contrary to the valves. *Seeds* one or more in each cell, kidney-ſhaped inclining to ovate.

Eſſ. Ch. Calyx double; the outer of many leaves or ſegments. Stigmas five. Capſule of five cells, with ſeveral ſeeds.

The ſpecies conſtituting the genus *Hibiſcus* are a numerous tribe of the largeſt and fineſt plants of the malvaceous order. They are 36 in Syſt. Veg. ed. 14th, 66 in Willdenow; yet of the former *H. præmorſus*, *ſpinifex*, *cancellatus*, and *zeylanicus*, are removed to the new genus *Pavonia*, and *H. Malvaviſcus* to the *Achania* of Banks and Solander, well marked by its convoluted corolla, ten ſtigmas, and pulpy fruit; ſee ACHANIA.—Scarcely any of them are natives of Europe. They generally grow between the tropics, yet ſome are found in North America, and ſome have been brought from the Cape of Good Hope. Though ſo numerous, they are not capable of being diſtributed into any well-defined ſections or ſubdiviſions.—The ſtem is generally ſhrubby or arboreous; rarely herbaceous with an annual root, and ſtill more rarely ſo with a perennial one. Leaves alternate, ſtalked, ſimple, more or leſs lobed, with a pair of narrow ſtipulas at the baſe of the footſtalk. Pubeſcence generally ſoft and ſtellated, ſometimes briſtly and ſimple, ſometimes wanting; in *H. populneus* ſcaly, but this was, with great reaſon, thought a diſtinct genus by Dr. Solander. Flower-ſtalks axillary or terminal, all ſimple and ſingle-flowered. Corolla uſually large, red, purpliſh, or yellow with more or leſs of a purple ſpot, for the moſt part very ornamental; ſometimes variable according to the age of the flower. The fibres of the ſtem are tenacious like hemp, and the juices of the whole plant very mucilaginous, ſometimes accompanied by an unpleaſantly ſcented ſecretion. We do not recollect any fragrance in the bloſſoms, at leaſt of thoſe few which it has fallen to our lot to examine alive in the gardens or ſtoves of Europe.—The following are among the ſpecies moſt worthy of notice.

H. *paluſtris*. Linn. Sp. Pl. 976. Curt. Mag. t. 882. Cavan. Diſſ. t. 65. f. 2.—Stem herbaceous, quite ſimple. Leaves ovate, partly three-lobed, downy beneath. Flower-ſtalks diſtinct from the foot-ſtalks.—Native of marſhes in North America; hardy in our gardens, but ſcarcely

Strahan and Preſton,
New-Street-Square, London.

flowering without ſome artificial heat. The *root* is perennial. *Stems* annual, about two feet high, perfectly unbranched, leafy, round, and nearly ſmooth. *Leaves* three or four inches long, two or three broad, pointed, ovate, ſerrated, often with two ſmall lateral points or lobes; ſmooth above; finely hoary beneath. *Flowers* large, roſe-coloured, darker in the centre. *Stamens* and *piſtil* yellow. *Stigmas* very large and globoſe. The *flower-ſtalks* are truly axillary, not united for ſome diſtance to the footſtalk of the leaf, by which it is ſuppoſed to be diſtinguiſhed from *H. Moſcheutos*; but we think, with Dr. Sims in Curtis's Botanical Magazine, that theſe two ſpecies are hardly to be conſidered as more than varieties. The latter is repreſented in Cavan. Diſſ. t. 65. f. 1, whatever may be the *Alcea roſea peregrina, forte Roſa moſcheutos Plinii,* Cornut. Canad. 144. t. 145.

H. *tiliaceus*. Linn. Sp. Pl. 976. Cavan. Diſſ. t. 55. f. 1. (Pariti; Rheede Malab. v. 1. 53. t. 30. Novella; Rumph. Amb. v. 2. 218. t. 73.)—Leaves roundiſh-heart-ſhaped, undivided, pointed, crenate. Stem arboreous. Outer calyx in ten ſegments united half way up.—One of the moſt common trees in every part of the Eaſt Indies, thriving in all ſorts of ſituations and ſoils, and cultivated for the ſake of its ſhade, even more than the beauty of its flowers, in towns and villages, and by road ſides. The *foliage* reſembles that of the Carolina Lime, *Tilia pubeſcens*. The *flowers* expand in an evening, and are pale yellow, with a dark purpliſh ſtain in the bottom. A coarſe cordage is made of the bark; the wood is light and white, uſeful for ſmall cabinet work; the mucilage of the whole plant is applied to ſome medical purpoſes.

H. *Roſa-Sinenſis*. Linn. Sp. Pl. 977. Sm. Spicil. 7. t. 8. Curt. Mag. t. 158. Cavan. Diſſ. t. 69. f. 2.) Schem-pariti; Rheede Malab. v. 2. 25. t. 17, with a double flower, as is alſo Flos feſtalis; Rumph. Amb. v. 4. 24. t. 8.)—Leaves ovate, pointed, ſerrated, ſmooth. Stem arboreous.—The native country of this ſpecies is uncertain, but no plant is more generally cultivated in China and the Eaſt Indies for ornament, eſpecially the double-flowered kind, which is uſed on all occaſions to decorate the houſes, temples, &c., as roſes are in England. Their ſhape and brilliant red colour have acquired them the appellation of the China Roſe. The ſingle flower, with its long pendulous column of ſtamens, and vivid crimſon ſtigmas, is in our opinion much more elegant than the double, but is rarely ſeen in collections, though the latter is conſidered as almoſt eſſential to every hot-houſe. The *tree* is ſaid to be as large as a hazel. The *leaves* are of a fine green, and ſmooth. *Flowers* large, crimſon. They ſerve the Europeans in India for the ignoble purpoſe of blacking their ſhoes, being rubbed upon the leather, which, when it has received a ſufficient degree of colour, is poliſhed with the hand.

H. *mutabilis*. Linn. Sp. Pl. 977. Andr. Repoſ. t. 228. Cavan. Diſſ. t. 62. f. 1. (Roſa-Sinenſis; Ferrari Flor. 479. t. 485—499. Merian. Surin. 31. t. 31. Hina-pariti; Rheede Malab. v. 6. 69. t. 38—42.)—Leaves heart-ſhaped, angular, five-lobed, pointed, toothed. Outer calyx of eight leaves. Capſule villoſe. Stem arboreous.—Native of China, Japan, and various parts of the Eaſt Indies, where, as well as in the Weſt Indies, it is much cultivated for the beauty of its flowers, moſt generally double, which are white at firſt opening in the morning, but become roſe-coloured before they fade at night. The *leaves* ſomewhat reſemble thoſe of the vine, and are roughiſh, variable in the length of their points. Ferrari and Rheede have illuſtrated this fine plant by an unuſual profuſion of plates in their ſeveral ſplendid works.

H. *ſyriacus*. Linn. Sp. Pl. 978. Curt. Mag. t. 83. Cavan. Diſſ. t. 69. f. 1. (Alcea arboreſcens; Camer. Hort. t. 3, 4. Althæa arboreſcens; Ger. em. 933. A. frutex; Park. Parad. 369. t. 367. f. 5.)—Leaves ovate, ſomewhat wedge-ſhaped, three-lobed, cut, ſmooth. Outer calyx of about eight leaves, as long as the inner. Stem arboreſcent.—Native of Syria and Carniola; a hardy ſhrub in our gardens, where it is popularly known by the name of *Althæa frutex*. It is perhaps the laſt ſhrub that comes into leaf with us, and one of the lateſt in flowering. The *bloſſoms* are handſome, roſe-coloured with a crimſon eye, produced in abundance, and liable to variations in colour which render them ſtill more deſirable. They have no ſcent.

H *liliiflorus*. Cavan. Diſſ. t. 57. f. 1.—Leaves obovate, entire, bluntiſh, ribbed, ſmooth; occaſionally three-lobed. Outer calyx five-cleft, very ſhort. Stem arboreous.—Gathered on the woody mountains of the Iſle de Bourbon by Commerſon, who, thinking it a diſtinct genus, intended to call it *Cremontia*. The above characters mark it ſufficiently. The *flowers* are large, not much expanded, purpliſh, externally ſilky and whitiſh. Few of the genus are more ſtriking either in their bloſſoms or foliage.—The French call it Fleur de St. Louis.

H. *ſpecioſus*. Ait. Hort. Kew. v. 2. 456. Curt. Mag. t. 360.—Leaves deeply palmate, ſmooth: their ſegments lanceolate, ſomewhat ſerrated. Stem, ſtalks, and calyx ſmooth.—Native of Carolina, nearly hardy with us, being perennial, with an annual herbaceous ſtem. The *flowers* are peculiarly ſhewy, being of a rich ſcarlet, and larger than moſt of their family.

H. *Abelmoſchus*. Linn. Sp. Pl. 980. Cavan. Diſſ. t. 62. f. 2. (Flos moſchatus; Merian. Sur. 42. t. 42.)—Leaves with ſeven angles, ſerrated; ſomewhat peltate and heart-ſhaped at the baſe. Stem briſtly.—Native of the Eaſt and Weſt Indies, chiefly remarkable for the rich muſky taſte of its ſeeds, known by the name of *Bammia moſchata*, for which they are cultivated in the Eaſt. The plant is ſhrubby, very hiſpid. *Leaves* very deeply divided. *Flowers* large, yellow. *Capſule* two or three inches long.

H. *Trionum*. Linn. Sp. Pl. 981. Curt. Mag. t. 209.—Leaves in three very deep diviſions, cut, ſomewhat pinnatifid. Calyx inflated, membranous, hairy.—The beautiful Venetian Mallow, or Flower of an hour, is one of the few European ſpecies of *Hibiſcus*, and alſo one of the few that are annual. It is commonly cultivated for the elegance of the flowers, which are ſulphur-coloured, with five purple external ſtripes, and a violet eye, contraſted with the yellow anthers. The purple hairy ſtigmas too are remarkable, as well as the bladdery hiſpid inner calyx.

Hibiscus, in *Gardening*, contains plants of the ſhrubby and flowering exotic ſorts, among which the ſpecies chiefly cultivated are, the Syrian ſhrubby hibiſcus, or althæa frutex (H. ſyriacus); the bladder hibiſcus, bladder ketmia, or flower of an hour (H. trionum); the China roſe hibiſcus (H. roſa ſinenſis); and the changeable roſe hibiſcus (H. mutabilis,) or Martinico roſe.

The firſt ſpecies has ſeveral varieties, as with pale purple flowers, having dark bottoms; with bright purple flowers, and black bottoms; with white flowers, and purple bottoms; with variegated flowers and dark bottoms, termed *painted lady althæa frutex*; with pale yellow flowers, and dark bottoms; and with variegated leaves, and double flowers.

And of the ſecond ſpecies there are varieties, with erect purpliſh ſtems, and larger flowers, with a deeper colour; and with large paler-coloured flowers.

The laſt ſpecies has alſo a variety with double flowers, from which the ſingle is often produced; but the ſeeds of the ſingle rarely afford plants that vary to the double ſort.

Method of Culture.—The firſt ſpecies is capable of being multiplied either by ſeeds, layers of the branches, or cuttings of the young ſhoots.

In raiſing them by ſeed, it ſhould be procured from abroad, and be ſown in the early ſpring ſeaſon, either in pots filled with light earth, or on a border in a warm expoſure; but the former is the better method. The pots muſt be plunged in a gentle hot-bed, in order to bring the young plants forward. Afterwards the plants ſhould be watered during the ſummer ſeaſon in a moderate degree, and be protected in the winter from the effects of froſt.

After the plants have had the growth of about two years they may be planted out in nurſery rows, or in the places where they are ultimately to grow.

Where the layer mode is employed, the branches ſhould be laid down into the ground in the autumnal ſeaſon, nicking the ſhoots on the back parts at one or two of the joints, and placing them well in the earth. They moſtly become pretty well rooted in the courſe of ten or twelve months, at which time they may be taken off, and placed out in their ſituations.

In uſing cuttings the young ſhoots ſhould be preferred, which ſhould be planted in pots of light earth early in the ſpring, plunging them in a mild hot-bed. They may alſo be planted in a ſhady border in the ſummer ſeaſon. As ſoon as the plants are become fully rooted, they ſhould be taken up with great care, and planted out where they are to grow, which may be done either during the autumn or in the ſpring.

The ſecond ſpecies may be increaſed by ſowing the well-ripened ſeeds in the autumn or ſpring, in patches of ſeveral ſeeds together, in the ſituations in which they are deſigned to grow and flower. As ſoon as the plants are come up, and have attained ſome growth, they ſhould be thinned out to two or three plants in each patch.

The laſt two ſpecies are alſo capable of being multiplied, by ſowing the ſeeds, when perfectly ripened, in the early ſpring in pots of rich light earth, plunging them directly in a moderate hot-bed, under glaſs frames, or, which is much better, in the bark-bed of the hot-houſe. As ſoon as the plants have made their appearance, and acquired ſome few inches in growth, they muſt be removed ſeparately into ſmall pots, giving them water freely, and then replunging them in the hot-bed, where they are to be preſerved.

In ſome caſes they are likewiſe capable of being raiſed by planting cuttings made from the young ſhoots in pots filled with the ſame ſort of mould, either in the ſpring or ſummer, affording them water immediately, and then placing them in the bark hot-bed. The after-management is the ſame as in the other ſorts.

The firſt two ſpecies, which are hardy, afford an excellent effect in the clumps and borders, in intermixture with other plants of the flowery ſort; while the laſt two, which are tender, diſplay conſiderable variety in collections of the ſtove and conſervatory kinds, by the beauty of their flowers.

HIBISI, in *Geography*, a town of Aſiatic Turkey, in Caramania; 80 miles W. of Satalia.

HIBRAHIM, or St. Mary, an iſland in the Indian ocean, near that of Madagaſcar; 50 miles long and 14 wide. S. lat. 16° 56′. E. long. 51° 56′.

HIBRETPOUR, a town of Hindooſtan, in Lahore; 27 miles N. of Firoſepour.

HICETAS, the Syracuſan, in *Biography*, an ancient philoſopher and aſtronomer, who flouriſhed at an unknown period. He was probably the firſt perſon who taught that the ſun and ſtars were fixed and permanent bodies, and that the earth had a rotatory motion. It is even ſaid that Copernicus derived from this philoſopher the firſt hint of his true ſyſtem of the univerſe.

HICHATAS, in *Geography*, a town of Weſt Florida, near the Apalachicola. N. lat. 31° 43′. W. long. 85°.

HICK, in *Nautical Affairs*, ſignifies the handle or lever of the rudder of a barge, called alſo the tiller.

HICKERY, in *Geography*, a town of America, in the ſtate of Pennſylvania, on the Alleghany; 20 miles N.E. of Fort Franklin.

HICKES, George, in *Biography*, was born at Newſham, in Yorkſhire, in the year 1642. He was educated at North-Allerton, from whence he was admitted a ſervitor at St. John's college, Oxford. Soon after the Reſtoration, he removed to Magdalen college, where he took the degree of B.A., 1662. He went to Lincoln college in 1664, was elected fellow, and in the following year commenced M.A. was admitted to holy orders, and undertook the office of a tutor to the college, the duties of which he diſcharged with great reputation till the year 1673, when he was obliged to ſeek for ſome change, in order to recruit his health, which had been injured by ſevere labour. He accompanied ſir George Wheeler in a tour on the continent, and at Paris he learnt that it was the intention of the court to revoke the edict of Nantz. In 1675 he returned to Oxford, obtained ſome preferment, and was ſoon after appointed domeſtic chaplain to the duke of Lauderdale, whom he attended to Scotland. Here he accepted the degree of doctor of divinity. From this period he received other preferments in the church, and among others, the deanery of Worceſter, and would probably have been made biſhop of Briſtol, but the death of the king, while the ſubject was in agitation, put an end to all his future hopes of eccleſiaſtical promotion. He had already diſcovered great zeal againſt the principles of popery, that he could expect no favour from James II.; nevertheleſs, he was ſo much of a churchman, and ſo ſteadily attached to the Stuart family, that he refuſed to take the oaths of allegiance to king William and queen Mary, was ſuſpended, and in 1690 was deprived of his benefices. Before he quitted poſſeſſion, however, upon ſeeing it announced in the Gazette that the deanery of Worceſter was granted to Mr. William Talbot, he drew up a claim of right to it, which, in 1691, he fixed up, in his own hand-writing, over the great entrance into the choir. This paper was called by the ſecretary of ſtate "Dr. Hickes's manifeſto againſt the government," and drew upon the author a proſecution from the officers of the crown. This he anticipated, and very wiſely quitted the country for concealment in the metropolis. Here and in its neighbourhood he remained unmoleſted till the year 1699, when the lord high chancellor Somers, out of regard for his great erudition, and as an encouragement to him in writing his dictionary of the old Northern languages, procured an act of council, by which the attorney-general was ordered to enter a *noli proſequi* to all proceedings againſt him. He died in 1715, in the ſeventy-fourth year of his age. His principal works were "Inſtitutiones Grammaticæ Anglo-Saxonicæ et Mæſo-Gothicæ," 4to; and "Antiquæ Literaturæ Septentrionalis, Libri duo", folio. This laſt is reckoned the author's maſter-piece, and is ſtill held in high eſtimation. He was author of three volumes of ſermons, and of a multitude of tracts in defence of himſelf, and the other non-jurors and their principles, an account of which may be found in the

the Biographia Britannica. Dr. Hickes was unqueſtionably a man of great learning, and very converſant in the writings of the Chriſtian fathers, whom he regarded as the beſt expoſitors of the ſcriptures. Of his integrity he afforded abundant evidence, by the ſacrifices to which he ſubmitted, rather than ſuffer his conſcience to be violated, and his moral conduct is ſaid to have been unexceptionable and exemplary. Biog. Brit.

Hickes's *Bay*, in *Geography*, a bay on the N.E. coaſt of New Zealand, diſcovered by Capt. Cook in 1769, ſo called from Mr. Hickes, the lieutenant of the Endeavour; 14 miles W.N.W. of Cape Runaway.

Hickes's *Keys*, a cluſter of iſlets and rocks, in the bay of Honduras, near the coaſt of Mexico. N. lat. 17° 10′. W. long. 88° 54′.

HICKFORD, in *Biography*, an Engliſh dancing-maſter, whoſe ſchool-room, in Brewer's-ſtreet, ſucceeded that in York-buildings for benefit concerts and muſical performances, during the early part of the laſt century.

In 1731, Geminiani Martini, the celebrated performer on the hautbois, and Arrigoni, the lutiniſt, had a weekly ſubſcription concert at Hickford's room; where Carborelli, Dubourg, Clegg, and Veracini had likewiſe their benefits, as had all the ſecond-rate opera ſingers. About the year 1744, Hickford himſelf eſtabliſhed a weekly ſubſcription concert, of which Feſting was the leader, Vincent the hautbois, Wiedman the German flute, Miller the baſſoon, Coperale the violoncello, and Fraſi, with ſome other Italians from the opera, the ſingers.

This concert continued in high favour till the deceaſe of Feſting and eſtabliſhment of Giardini in this country.

HICKMAN, in *Geography*, a ſettlement of America, in Fayette county, Kentucky, on the N. ſide of Kentucky river; 10 miles N. of Danville.

HICKSFORD, a poſt-town of America, in Greenville county, Virginia; 209 miles from Waſhington.

HICKUP, Hiccock, or *Hiccough*, in *Medicine*, terms which have probably originated from the peculiar ſound iſſued in the affection which they are uſed to denote, ſignify a rapid, convulſive, and ſonorous inſpiration, effected by the motion of the diaphragm, and generally connected with irritation of the ſtomach. It is the λυγμὸς or λύγγος of the Greeks, and the *ſingultus* of the Latins.

This troubleſome ſpaſmodic affection is too well known to require any minute deſcription here. Some have conſidered it as a diſorder of the ſtomach excluſively; while others more correctly aſſert, that the action of the diaphragm is principally concerned in producing it. It is obvious, indeed, that the peculiar diſſyllabic ſound, produced during the ſpaſm, commonly ariſes from an affection of ſome of the organs of reſpiration, and this is not leſs obviouſly the diaphragm. This ſpaſmodic contraction of the diaphragm, however, is moſt excited in conſequence of ſome irritation within the ſtomach, and eſpecially about the upper orifice or cardia. Thus a large quantity of food, taken without drinking, or a ſmall portion of very dry food, ſuch as bread, will often bring on the hickup; but it is ſpeedily appeaſed, in ſuch caſes, by a draught of any liquid. Diſtenſion of the ſtomach, by a very copious meal, or by food imperfectly maſticated, will alſo frequently induce a hickup; which, of courſe, is eaſily prevented by an oppoſite courſe, temperance, and ſlow eating. Certain acrid ſubſtances, ſwallowed, or generated in the ſtomach, are apt to excite the convulſive action of the diaphragm, which conſtitutes hickup. Thus various ſpices, eſpecially when taken copiouſly, and other pungent matters, ſuch as garlic, &c. often produce it; and the acids, and other irritating fluids, which reſult from imperfect digeſtion, and occaſion a ſenſe of heat and uneaſineſs about the cardia, or heart-burn, frequently alſo excite hickup.

On the other hand, hickup is often obſerved to ariſe from the oppoſite ſtate of the ſtomach to that of over-diſtenſion, namely, from inanition. It is not ſo eaſy to account for this variety of the diſorder, unleſs we ſuppoſe that the fluids, ſecreted within the ſtomach, become, during its empty ſtate, a ſource of irritation adequate to excite the ſympathetic action of the diaphragm. Hickup is alſo apt to occur, after great evacuations by purging and vomiting, as in cholera, and after hemorrhages. And it often accompanies inflammation, or other ſevere irritation, in the viſcera, eſpecially thoſe of the abdomen, in phrenitis, or inflammation of the brain, in apoplexy, in obſtructions of the bowels, &c. It is very common in almoſt all diſorders of the organs connected with digeſtion: thus it is generally one of the ſymptoms of a ſcirrhous ſtate of the liver; and is ſometimes found in ſimple jaundice, in which the biliary ducts are obſtructed, although the liver itſelf is ſound. Sometimes it is one of the fore-runners of the epileptic paroxyſm. Heberden's Comment.

From ſome one or other of theſe cauſes, hickup will ſometimes continue to diſtreſs the patient, not only for ſeveral months, but even for ſome years, at times with great conſtancy, and at other times with conſiderable intermiſſions. In ſome inſtances, this troubleſome ſymptom has been known to haraſs a perſon during the ſpace of many months, without any other ſigns of ill health. (See Heberden, Comment. De Morbor. Hiſt. et. Curat. cap. 81.) The final cauſe of the hickup has been ſuppoſed to be the removal of any irritating ſubſtance from the lower part of the œſophagus, or from the upper orifice of the ſtomach to a leſs ſenſible part of that organ by the concuſſion of the whole.

The hickup, in its moſt ordinary form, where no particular diſeaſe is preſent, is a trifling affection; but when it is a ſymptom of other diſeaſes, and eſpecially of acute or febrile diſeaſes, it is often itſelf a ſevere complaint, by the irritation which it produces, and very often indicative of danger, or of the approach of diſſolution. Hippocrates has founded ſeveral of his prognoſtic aphoriſms upon this ſymptom. In inflammation of the bowels (enteritis), in long continued colic, in ſtrangulated hernia, in ſtricture of the rectum, intus-ſuſceptio, or other impediment to proper evacuation of the canal, hickup enſues towards the cloſe of the diſeaſe, and, when accompanied by great fulneſs and tenſion of the abdomen, with debility of the pulſe, languor, and proſtration of ſtrength, is to be conſidered as a moſt unfavourable ſymptom. In all acute fevers it is an unpleaſant ſymptom, implying generally a morbid condition of the abdominal viſcera or of the brain, which it is to be apprehended will terminate unfavourably. The ſymptom, however, has ſometimes preceded a favourable change of the fever; ſo that the older phyſicians have remarked, that an exception from its indication of danger ariſes, when appearances of an approaching criſis concur with it. Hippocrates obſerves that hickup is a bad ſymptom in old people after a ſevere purging. (Aphoriſm 41. ſect. 7.) It is unfavourable, indeed, after every ſevere evacuation of this ſort; but more particularly in the aged, whoſe ſtrength is neceſſarily impaired. He remarks, too, that hickup is a bad ſymptom in inflammation of the liver (Aph. 58. ſect. 5—17. ſect. 7), and that a ſneezing, ſupervening during a hickup, removes it. Aph. 7. ſect. 6.

It is ſcarcely neceſſary to ſpeak of *the cure of hickup,* ſince it is either ſo ſlight an affection, in general, as to require no medical aſſiſtance, on the one hand ; or a ſymptom of ſome other diſeaſe, to which our attention muſt be chiefly directed, on the other. In the former caſe, it uſually ceaſes ſpontaneouſly in a ſhort time, or is readily removed by a little warm fluid, as tea, coffee, and the like. When it ariſes from over-diſtenſion of the ſtomach by a too copious ſupply of food, or from the uſe of certain ſpices or other acrid ſubſtances, it will be in the patient's power to avoid any return of it in future from the ſame cauſes. When the hickup is more permanent and troubleſome, moderate doſes of the antiſpaſmodics will commonly relieve it ; probably by blunting the ſenſibility of the nervous coat of the ſtomach, and invigorating its muſcular fibres. Thus a little opium or conium (cicuta of the old pharmacopœias), or a few drops of the tincture of opium and of ſulphuric ether, will frequently remove the paroxyſm at once. When the hickup appears to be connected with the generation of acid in the ſtomach, it may be alleviated by magneſia, chalk, and the alkaline waters, at the ſame time, a light and moderate diet, with occaſional laxatives, and aromatic bitters, may be uſed with a view to unload and ſtrengthen the ſtomach. This, like many other ſpaſmodic actions of muſcular parts, may be often removed by drawing the attention of the patient ſtrongly to any particular object, or by exciting any mental emotion ; a fact, which popular obſervation has evinced. When the hickup is merely a ſymptom of ſome other diſeaſe, the treatment of it is a matter of very ſecondary importance ; our efforts being of neceſſity directed chiefly to the removal of the primary diſeaſe, with the ceſſation or alleviation of which the hickup will of courſe ceaſe or be alleviated, according to the old maxim, " ſublatâ cauſâ tollitur effectus." The treatment of ſuch primary diſeaſes will of courſe be elſewhere detailed. See Sennertus, Med. Pract. lib. iii. part 2. ſect. 2. cap. 10. Hoffmann, Syſt. Med. Rat. Heberden, Comment. cap. 81. Sauvages, Noſol. Method.

HICKWALL, in *Ornithology,* the name of a ſmall ſpecies of wood-pecker, called by authors picus varius minor ; a ſmall bird of not above an ounce weight, very beautifully variegated with black, white, and brown. The head in the female of this ſpecies has a white ſpot on the crown, and in the male a red one. It climbs trees like the common large wood-pecker, and like it feeds on worms and other inſects which it finds there. See Picus *Minor.*

HID *Iſland,* in *Geography,* an iſland of the N.W. territory of America, in Plein river, the northern head-water of the Illinois.

HIDAGE, or Hydage, an extraordinary tax, anciently payable to the king for every hide of land. See Hide.

" Sunt etiam quædam communes præſtationes, quæ ſervitia non dicuntur, nec de conſuetudine veniunt, niſi cum neceſſitas intervenerit, vel cum rex venerit ; ſicut ſunt hidagia, coragia, & carvagia, & alia plura de neceſſitate, & ex conſenſu communi totius regni introducta, & quæ ad dominum non pertinent," &c. Bracton, lib. ii. cap. 6.

King Ethelred, in the year of Chriſt 994, upon the landing of the Danes, at Sandwich, taxed all his lands by hides. Every 310 hides of land, on this occaſion, found one ſhip furniſhed ; and every eight hides found one jack and one ſaddle, for the defence of the realm. William the Conqueror took ſix ſhillings for every hide of land in England.

Hidage is alſo uſed for being quit of that tax ; otherwiſe called *hide-gild.*

HIDALGO, *q. d. a ſon of birth,* in *Modern Hiſtory,* a title given in Spain to all who are of noble family.

HIDDE, in *Geography,* a town of Arabia ; 10 miles E. of Jidda.

HIDDENSON, an iſland in the Baltic, near the W. coaſt of Uſedom, about ten miles long and two broad. N. lat. 54° 35'. E. long. 13° 10'.

HIDE, in *Commerce,* the ſkin of a beaſt ; particularly that of a bullock, cow, or horſe. See Skin and Tanning.

We have hides of divers denominations, according to their ſtate, quality, &c.

Hide, *Curried,* is that which, after tanning, has paſſed through the currier's hands, and has thus received its laſt preparation, and is fitted for uſe. See Currying.

Hide, *Raw,* or *Green Hide,* is that which has not undergone any preparation ; being in the ſame condition as when taken off the carcaſe.

Hide, *Salted,* is a green hide, ſeaſoned with ſea-ſalt and alum, or ſalt-petre, to prevent its ſpoiling and corrupting, either by keeping it too long in cellars, or in tranſporting it too far in a hot ſeaſon.

There are alſo hides dried in the air, ſent from America ; particularly thoſe of buffalos.

Hide, *Tanned,* is a hide either green, ſalted, or dried, farther dreſſed and prepared by the tanner, by paring off the hair, and ſteeping it in pits of lime and tan. See Tanning.

Tanned hides are commonly carried along with the artillery of an army. They are uſed in the fire-workers ſtores, for covering powder or charged bombs from the rain or from ſparks of fire. They are alſo uſed on batteries, or in a laboratory.

Hide, or *Hyde, Hyda,* in our *Ancient Cuſtoms,* denoted a meaſure or quantity of land, containing ſo much as could be yearly tilled with a ſingle plough.

Beda calls the hide of land *familia,* and defines it to be ſo much as was ſufficient for the ordinary maintenance of one family. In other authors it is called *manſum, manſio, carucata,* &c.

Crompton, in his juriſdict. fol. 322, ſays, a hide of land contains one hundred acres, = 10 acremes = 10 ſquare furlongs = 4 virgates = 8 bovates or ox-gangs = 8 nooks = 200 obolata = 400 roods = 16,000 perches or poles = 1000 ſquare chains = 100,000 ſquare ſtaves = 10,000,000 ſquare links = 484,000 ſquare yards = 1,742,400 ſquare paces = 4,356,000 ſquare feet, &c. : he adds, that eight hides make a knight's fee. In ancient manuſcripts, the hide is fixed at 120 acres. But ſir Edward Coke notes, that a knight's fee, a hide or plough-land, a yard-land, and an ox-gang of land, do not contain any certain determinate number of acres. See Carrucate.

The diſtribution of England into hides of land is very ancient, there being mention made of it in the laws of king John, cap. 14. " Henricus I. maritand. filiæ ſuæ gratia imperatori, cepit ab unaquaque hida Anglia tres ſol." Spelman. See Subsidy.

Hide, in *Geography,* a river in America, which runs into the Miſſiſſippi, N. lat. 43° 24'. W. long. 92° 2'.

Hide *and Gain,* in our *Old Writers,* ſignified arable land ; to gain the land being as much as to till it.

Hide-*bound,* a diſorder of a horſe or other beaſt, wherein his ſkin ſticks ſo tight to his ribs and back, as not to be looſened from it with the hand.

The diſorder is ſometimes owing to poverty and bad keeping ; at other times to over-riding or a ſurfeit, the horſe being ſuffered when he is hot to ſtand long in the wet ; or to a morbid dryneſs of the blood, which, not having its natural courſe, cauſes the ſkin to ſhrink up and cleave to the bones.

Among *Huſbandmen*, trees alſo are ſaid to be hide-bound when the bark ſticks too cloſe.

Hide-*bound Land*, in *Agriculture*, a term uſed in ſome diſtricts to denote tough, poor ſward land, which has moſtly been badly laid down to graſs.

HIDEL, in our *Ancient Statutes*, ſignifies a place of protection or ſanctuary.

HIDGILD, or Hidegild, in the laws of king Canute, is explained by *pretium redemptionis ſervi;* the price by which a ſervant was to redeem his ſkin from being whipped.

The word is formed from the Saxon *hide*, ſkin, and *gild*, payment. "Si liber feſtis diebus operetur perdat libertatem; ſi ſervus corium perdat vel hidgildum:" *i. e.* let him be whipped (which was the puniſhment for ſervants), or let him pay for his ſkin; by which payment he is to be excuſed from whipping.

HIDRA, in *Geography*, a town of Africa; 110 miles W.S.W. of Tunis.

HIDRO, a mountain of Naples; 15 miles W.S.W. of Otranto.

HIDROA, *ἱδρωα*, in *Medicine*, from *ἱδρως*, *ſweat*, ſignifies an eruption of miliary puſtles on the ſkin, occurring chiefly during the ſummer, in the ſouth of Europe. The complaint was entitled *ſudamina* and *papulæ ſudoris* by the Romans, *ſudor* ſignifying alſo *ſweat;* whence we may infer their opinion of its connection with the perſpiration, which the hot ſeaſon produced. It appears to be nearly the ſame diſeaſe as that which occurs in tropical climates during the hotteſt months, eſpecially to European ſettlers, and is denominated, from the ſenſation accompanying it, the *prickly heat*. See Heat, *prickly*.

HIDROCRITICA, a term uſed to expreſs the judgments paſſed by phyſicians on their patients, on obſerving the ſweats that have attended the diſeaſe.

HIDRONOSOS, a name given, by ſome authors, to that terrible diſeaſe the ſudor Anglicanus, or ſweating ſickneſs.

HIDROPYRETOS, of *ἱδρως*, *ſweat*, and *πυρετος*, *fever*, *the ſweating fever*, a name given by ſome to the ſudor Anglicus, or ſweating ſickneſs.

HIDROTICS, or Hydrotics, in *Medicine*, the ſame with ſudorifics.

The word is compoſed of the Greek *ἱδρως*, *ſweat*.

Contrayerva, zedoary, guaiacum, angelica, &c. are of the number of hidrotics, or hidrotic medicines.

HIELM, in *Geography*, a ſmall iſland of Denmark, in the Cattegat, near the coaſt of Jutland. N. lat. 56° 8'. E. long. 10° 49'.

HIELMAR, a lake of Sweden, in the province of Sudermanland, about 70 miles in circumference; 60 miles W. of Stockholm.

HIEMALIA, in *Antiquity*, the ſame with brumalia.

HIEN, in *Geography*, a town of China, of the third rank, in the province of Pe-tche-li, 12 miles S. of Ho-kien.

HIEN-YAN, a town of China, of the third rank, in Chan-ſi; 12 miles W.S.W. of Si-nghan.

HIEOU-KI, a town of China, of the third rank, in Fo-kien; 26 miles S. of Yen-ping.

HIEOU-NHING, a town of China, of the third rank, in Hou-quang; 40 miles S. of Ou-tchang.

HIERA, in *Ancient Geography*, one of the Cyclades, an iſland of the Archipelago, ſituated between Thera and Theraſia. This iſland, called the "Sacred iſland," was dedicated to the gods of hell, becauſe it had been ſeen to iſſue, all on fire, from the bottom of the ſea, as the effect of a volcano. Pliny ſays that this event took place 150 years after that which had ſeparated Thera from Theraſia. M. de Choiſeul affirms, according to father Hardouin, that there is a miſtake in the dates, and that it was not till 40 years after that the iſland of Hiera made its appearance. In the year 196, B. C., ſays Juſtin (l. xxx. c. 4.), there was ſeen to iſſue, after an earthquake, an iſland between Thera and Theraſia, which was called "Sacred," and which was dedicated to Pluto. Dion Caſſius mentions the ſudden appearance of a ſmall iſland near that of Thera, during the reign of Claudius. Syncellus mentions it in the 46th year after Chriſt, and places it between Thera and Theraſia. But it appears that, ſome time after, there aroſe another iſland called Thia, which diſappeared, or was united to the "Sacred" iſland. Mention is made of it in Pliny (l. iv. c. 12.), in Theophanes, and in Brietius (vol. ii. p. 236.) Nothing remarkable happened afterwards till 1427, when a great exploſion produced a rather great and very diſtinguiſhable increaſe to the iſland of Hiera, of which mention is made in ſome Latin verſes engraved on a marble at Scauro, near the church of the Jeſuits. In 1573 was formed, after a freſh exploſion of ſome continuance, the "Little Kammeni," ſuch as we ſee it at the preſent day. The iſland Hiera, called "Old Kammeni," to diſtinguiſh it from "New Kammeni" (ſee Kammeni), is upwards of a mile in length, and appears to be nothing but a maſs, without regular ſtrata, of volcanic ſubſtances, and particularly of rocks of baſaltes. It is covered with a little earth, mixed with pumice-ſtones and volcanic aſhes, which have given riſe to the vegetation that has been there long eſtabliſhed. This iſland is deſert and uncultivated. In the ſummer only aſſes and mules are ſent thither to graze. On the part, ſuppoſed to have been added to it at a later period, there is not as yet any trace of vegetation, and this part remains leſs elevated than the reſt of the iſland. On Hiera are obſerved clefts ſomewhat conſiderable, which take the direction of its length, and extend almoſt from the one extremity to the other. Theſe have, without doubt, been occaſioned by the earthquakes which have very frequently occurred in theſe countries. Olivier's Travels in the Ottoman Empire.

HIERACHIOIDES, in *Botany*, a name given by Vaillant to a genus of plants, ſince called by Linnæus *Crepis;* which ſee.

HIERACITES, Hieracitæ, in *Eccleſiaſtical Hiſtory*, a ſect of ancient heretics, at the cloſe of the third century, denominated, from their leader Hierax, a bookſeller of Leontium, and eminently diſtinguiſhed by his extenſive learning, and a venerable air and ſanctity of virtue.

He abſolutely denied the reſurrection of the body, maintaining, that the ſoul alone roſe again, and that the reſurrection was altogether ſpiritual. Epiphanius ſurmiſes that he might have imbibed this error from Origen.

The ſame Hierax, and his followers, likewiſe condemned the uſe of fleſh, wine, and marriage; being of opinion that they were only allowed under the Old Teſtament, and till the coming of Jeſus Chriſt; but that under the new law they were prohibited, as incompatible with the kingdom of God.

St. Epiphanius produces the paſſages of ſcripture whereon he founded this doctrine. He adds, that Hierax did not adopt Origen's opinion with regard to the Trinity, but allowed the Son to be really and truly begotten of the Father. He was alſo orthodox with reſpect to the Holy Ghoſt, excepting for ſome peculiarities received from the Melchiſedecians, on which he had refined, maintaining that Melchiſedec was the Holy Ghoſt. He alſo excluded from the kingdom of heaven children, who died before they had arrived to the uſe of reaſon. He lived a very auſtere life, and promoted the ſame among his followers; but, after his death, they degenerated very rapidly.

HIERACIUM, in *Botany*, from ἱέραξ, *a hawk*, becauſe hawks were ſuppoſed to ſharpen their ſight by the application of its juice to their eyes. The abſurdity of the idea proves the venerable antiquity of the name. Hawkweed.—Linn. Gen. 402. Schreb. 529. Willd. Sp. Pl. v. 3. 1559. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 827. Ait. Hort. Kew. v. 3. 121. Juſſ. 169. Tourn. t. 267. Lamarck. Illuſtr. t. 652. Gærtn. t. 158.—Claſs and order, *Syngeneſia-Polygamia-æqualis.* Nat. Ord. *Compoſitæ ſemifloſculoſæ*, Linn. *Cichoraceæ*, Juſſ.

Gen. Ch. *Common Calyx* imbricated, ovate, of many linear, very unequal, longitudinal and incumbent ſcales. *Cor.* compound, imbricated, uniform; the florets hermaphrodite, numerous, equal, each of one petal, ligulate, linear, abrupt, with five teeth. *Stam.* Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* Germen nearly ovate; ſtyle thread-ſhaped, the length of the ſtamens; ſtigmas two, recurved. *Peric.* none, except the cloſed, ovate, permanent calyx. *Seeds* ſolitary, ſhort, obtuſely quadrangular; down capillary, ſeſſile. *Recept.* nearly naked.

Eſſ. Ch. Receptacle nearly naked, dotted. Calyx imbricated, ovate. Down ſimple, ſeſſile.

Obſ. This genus is far more comprehenſive in Tournefort than in Linnæus, embracing various ſpecies of *Crepis*, *Hypochæris*, *Picris*, &c. The *Hieracia* of Vaillant have all branched ſtems; that author ſeparating from them, by the name of *Piloſella*, ſuch as have ſimple radical flower-ſtalks.

Thirty-five ſpecies are defined in the 14th edition of the *Syſtema Vegetabilium*, 70 in Willdenow's *Species Plantarum*, though many of the former are now ſent away, by the laſt-mentioned author, to his *Apargia* and other genera. Some indeed are removed by him into this genus from *Leontodon* and *Crepis*, but its chief increaſe is derived from new diſcoveries in the mountainous parts of Europe.

The whole are commodiouſly and naturally divided into three ſections; 1ſt, ſtalks radical, ſingle-flowered; 2dly, ſtalks radical, many-flowered; 3dly, ſtem leafy.

They are almoſt, without exception, perennial herbaceous plants, *H. glutinoſum* only having an annual root, and *H. fruticoſum*, Willden. n. 69, a ſhrubby ſtem. Their herbage is commonly hairy or rough, eſpecially the calyx and top of the flower-ſtalks, which are in many inſtances clothed with denſe, black, partly glandular, prominent, ſoft hairs. The leaves are ſimple, now and then ſpotted, uſually entire in ſuch ſpecies as are but little or not at all cauleſcent, more or leſs deeply toothed, or even pinnatifid, in the reſt. Thoſe placed on the ſtem are alternate, ſeſſile, or frequently claſping that part by their arrow-ſhaped or heart-ſhaped baſe. The flowers are diurnal, of a full golden yellow, in a very few inſtances orange or lemon coloured, and in ſtill fewer pink or purpliſh. Though the ſeed-down is properly deſcribed as ſimple, it is very generally rough, often verging towards a feathery ſtructure.

Examples of the firſt ſection are,

H. alpinum. Linn. Sp. Pl. 1124. Fl. Lap. n. 283. Lightf. Scot. 434. t. 18. Engl. Bot. t. 1110. (H. villoſum alpinum, flore magno ſingulari, caule nudo; Dill. in Raii Syn. 169. t. 6. f. 2.) Leaves oblong, undivided, entire or notched. Stalk almoſt leafleſs, ſingle-flowered. Calyx hairy.—Found on all the higheſt mountains of Europe, in rocky places, flowering in July. It is remarkable for its large ſolitary *flower*, whoſe calyx is black, clothed with long denſe tawny hairs. The *leaves* vary much in the number and depth of their marginal inciſions—Willdenow quotes for this Jacquin's Fl. Auſtr. t. 191, which he had properly cited at the ſpecies immediately preceding as *H. alpeſtre* of that author, very diſtinct from the *alpinum*, in its downy more ſlender calyx, regularly toothed leaves, and taller ſtem.

H. *Piloſella.* Linn. Sp. Pl. 1125. Curt. Lond. faſc. 4. t. 54. Engl. Bot. t. 1093. Bulliard. Fr. t. 279. (Piloſella repens; Ger. em. 638.)—Leaves elliptical, entire, downy beneath. Scions creeping. Stalk ſingle-flowered, leafleſs.—Very common throughout Europe in dry expoſed places, on gravelly banks, ſunny lawns, and the tops of park walls, where it bloſſoms from May to the end of July, expanding its bright ſulphur-coloured flowers, elegantly ſtriped at the back with crimſon, to the meridian ſun, "while the ſurrounding herbage, and even its own foliage, is withered and burnt up." The flowers cloſe early in the afternoon. The *leaves* are beſet with long rigid briſtles, and ſingularly white beneath. The plant ſpreads widely by means of its long trailing leafy runners; on the Alps they are ſhorter, and the flowers larger. There is alſo an alpine variety, whoſe leaves are white on both ſides.

Whether Willdenow has done right in referring the Linnæan *Leontodon bulboſum* hither, the only ſpecimen we have of that rare plant will not enable us to decide, but every character in its outward appearance ſhews that it ought not to be generically ſeparated from *L. tuberoſum*, which he reckons an *Apargia*.

In the ſecond ſection (ſtalks radical, many-flowered,) are H. *dubium.* Linn. Sp. Pl. 1125. Fl. Brit. 828. Tr. of Linn. Soc. v. 9. 226. (H. Auricula; Fl. Dan. t. 1111. H. n. 53. Hall. Helvet. v. 1. 22. Piloſella major prima; Tabern. Kreuterb. 507.)—Leaves elliptic-lanceolate, nearly entire, hairy. Scions creeping. Stalk with ſeveral flowers. Native of rather moiſt mountainous paſtures. Mr. Hudſon and Mr. Woodward are both mentioned as having gathered it in the north of England, and we have from the Cambridge garden roots, ſaid to be natives of Scotland. It differs from the laſt chiefly in having the *leaves* green on both ſides, and the *flowers* two, three, or four, on each ſtalk, of a ſulphur colour underneath as well as above. Some botaniſts have confounded the ſynonyms of the preſent with the following, on which ſubject copious illuſtrations may be ſeen in the Tranſactions of the Linnæan Soc. v. 9. 225.

H. *Auricula.* Linn. Sp. Pl. 1126. Fl. Brit. 829. (H. dubium; Fl. Dan. t. 1044. H. n. 52; Hall. Helvet. v. 1. 22.)—Leaves lanceolate, entire. Scions creeping. Stalk nearly leafleſs, many-flowered, umbellate.—On mountains in various parts of Europe, eſpecially in the moſt lofty ſituations about the Glaciers of Switzerland. Mr. Hudſon mentions gathering it on Dalehead, not far from Graſſmere, Weſtmoreland, though ſparingly. We never ſaw a Britiſh ſpecimen. What is ſhewn for it in the botanic gardens is a mere variety of the laſt. The preſent has fewer *runners*, perfectly lanceolate *leaves* not dilated into a round or obovate ſhape, except one or two of the loweſt, and ſmaller *flowers*, of a deeper, almoſt orange colour, with a far more hairy calyx.

H. *aurantiacum.* Linn. Sp. Pl. 1126. Jacq. Auſtr. t. 410. Don. Herb. Brit. faſc. 2. 41. Sm. Engl. Bot. t. 1469. (H. hortenſe latifolium, ſive Piloſella major; Ger. em. 305.)—Leaves elliptical, entire. Stem nearly leafleſs, ſimple, hairy, bearing a corymbus of many flowers.—Found in mountainous woods in France, Italy, Switzerland, and Germany, but it was not known to be a native of Britain till Mr. G. Don diſcovered it in ſeveral woods in Banffſhire, and at Craigſton, near Turref, North Britain. In gardens it has long been known by the name of Grim the

Collier, and is diſtinguiſhed by the rich orange hue of its *corolla*, contraſted with the black hairy *calyx*. It blooms in July, and forms large tufts if planted in ſhady places.

H. *incarnatum*. Jacq. Ic. Rar. t. 578.—Leaves obovate-oblong, wavy and toothed, hairy. Stalk many-flowered, ſomewhat corymboſe, rough at the baſe, leafleſs. Calyx ſmooth.—Native of ſubalpine places in Carinthia and Carniola, very remarkable for its elegant pink *flowers* and deeper red anthers. The *leaves* are all radical, two or three inches long, light green, rough, with numerous ſhort rigid hairs. *Stalk* about a foot high, ſlender, naked, bearing a ſort of corymboſe panicle.

H. *Gmelini*. Linn. Sp. Pl. 1127. (H. foliis ex ſinuato dentatis, caulibus ſupra ramoſis ſubnudis, pedunculis hirſutis unifloris; Gmel. Sib. v. 2. 23. t. 8. f. 2.)—Leaves lyrato-runcinate, ſmooth. Stalk leafleſs, corymboſe.—Gathered in Siberia by Steller, and communicated by Gmelin to Linnæus. The moſt curious particular in the hiſtory of this plant is that a birch leaf, happening to ſtick to the bottom of the ſpecimen, cauſed Linnæus to define it "with radical leaves ovate, ſerrated, and ſmooth." This ſtrange error could not have been gueſſed without an inſpection of his herbarium. "*Quandoque bonus dormitat Homerus.*"

In the third ſection (with leafy ſtems,) are,

H. *paniculatum*. Linn. Sp. Pl. 1127.—Stem erect. Leaves numerous, elliptic-lanceolate, toothed, naked. Panicle capillary, divaricated.—Found by Kalm in Canada. We have it alſo, from the Rev. Dr. Muhlenberg, gathered near Lancaſter, in Pennſylvania. The *ſtem* is 12 or 18 inches high, terminating in a ſingularly delicate, ſmooth, wide-ſpreading panicle, of ſmall yellow flowers, not half the ſize of our common *Lapſana*.

H. *montanum*. Jacq. Auſtr. t. 190. Willd. n. 36. (H. n. 38; Hall. Helvet. v. 1. 16. H. latifolium montanum præaltum glabrum, endiviæ folio; Bocc. Muſ. v. 1. 148. t. 113. Hypochæris pontana, an error of the preſs for montana; Linn. Sp. Pl. 1140. Andryala pontana; Villars. Dauph. v. 3. 67. t. 23.)—Stem ſimple, leafy, ſingle-flowered. Leaves ſeſſile, obovato-lanceolate, with hooked teeth. This fine ſpecies grows on the alps of Auſtria, Savoy, Switzerland, and Dauphiny. The *root* is externally black, and runs deep into the ground. *Stem* from one to near three feet high, ſimple, ſolid, furrowed, roughiſh; leafy in the lower part; elongated and naked at the top, bearing one large handſome yellow *flower*, whoſe calyx is black, ſhaggy, and ſomewhat tawny. The *leaves* are about three inches long, acute, thin, veiny, ſmooth, edged with ſmall, unequal, more or leſs hooked, teeth. Linnæus in his own copy of Sp. Pl. has corrected the error of the preſs, which led his tranſcribers aſtray, but which any of them might eaſily have detected by turning to Boccone; yet Willdenow copies the ſynonym of the latter, retaining the error in queſtion, as well as another referring to vol. 2. inſtead of 1. We cannot too often inſiſt on the editors of any of the works of Linnæus turning to, and correcting, quotations. This at leaſt is in their power, and would be far more uſeful than many alterations, concerning which their judgment and experience may poſſibly be inferior to that of their author. In the latter part of this cenſure we aim not at our friend Willdenow, who, except ſome trifling or erroneous changes in ſpecific characters, and his univerſally copying from the original edition, like his predeceſſors, remarks, that theſe apply to an immediately preceding ſpecies, without altering ſuch reference, though he introduces ever ſo many new ones between the two, (witneſs his *Hieracium paludoſum*, n. 44.) has proved himſelf in many reſpects a highly meritorious editor.

Several more ſpecies of this ſection are found on the continent, and many of them in Britain. The latter, as far as hitherto determined, are *H. murorum*, Engl. Bot. t. 2082; *maculatum*, t. 2121; *ſylvaticum*, t. 2031; *Lawſoni*, t. 2083, which we are rather inclined to place here on account of its affinity to the reſt, though (like *murorum* indeed,) it has but one or two ſtem-leaves; *paludoſum*, t. 1094; widely different from *murorum*, notwithſtanding the ſuſpicion of Linnæus; the ſtem is hollow; whole plant intenſely bitter; *cerinthoides*, Linn. Sp. Pl. 1129, found in the Highlands, by Mr. G. Don; *molle*, Engl. Bot. t. 2210; *villoſum*, Jacq. Auſtr. t. 87; *ſabaudum*, Engl. Bot. t. 349; *denticulatum*, t. 2122; *prenanthoides*, t. 2235; and *umbellatum*, t. 1771. We have imperfect ſpecimens of ſeveral more, either varieties or ſpecies, from Scotland, but they require to be cultivated and obſerved in different ſtates, before they can be finally ſettled, this being one of the moſt difficult of European genera, in which it vies with *Saxifraga* and *Potentilla*. S.

HIERACIUM, in *Gardening*, contains plants of the herbaceous hardy, flowering perennial ſorts, of which the ſpecies moſt uſually cultivated are, the orange-flowered hawkweed (H. aurantiacum); and the gum-ſuccory hawkweed (H. chondriloides.) The former is frequently diſtinguiſhed by the name of golden mouſe-ear, and when of a dark colour by that of Grim the collier. And it varies in the colour of the flower from red to orange, as well as ſeveral ſhades of yellow.

Method of Culture.—Theſe different ſpecies of plants are capable of being increaſed by means of ſowing the well ripened ſeeds early in the ſpring upon a bed or border of freſh earth, which has an expoſure towards the eaſt. As ſoon as the plants have a few inches growth, they muſt be removed into other beds in order to ſtand until the autumn, when they ſhould be planted out where they are to remain. A better practice is, however, that of at firſt ſetting them where they are intended to continue.

They are alſo capable of being multiplied by means of ſlips from the roots, which ſhould be planted in the autumn or ſpring in the places where the plants are to remain. In each of theſe modes of increaſing them, they ſhould have pretty full ſupplies of water in dry ſeaſons.

When planted in ſuch ſoils as are neither too rich, nor too much filled with moiſture, the roots will continue for a great number of years.

Theſe plants give variety in the clumps, borders, and other parts of pleaſure grounds, in which they ſhould conſtantly be placed towards the fronts.

HIERACOME, in *Ancient Geography*, a town of Aſia, in Syria, ſituated to the eaſt of the gulf of Iſſicus, between two chains of mountains.

HIERACUM, a town of Upper Egypt, in the Thebaide, placed in Antonine's Itinerary between Iſiu and Peſla; 20 miles from the former and 28 from the latter.

HIERACURRA, in *Geography*, a town of Hindooſtan, in Golconda; 35 miles S.E. of Hydrabad.

HIERÆA, in *Ancient Geography*, a ſmall country of Libya.

HIERAMÆ, a town of Aſia, in Caria. Steph. Byz.

HIERA PICRA, in *Pharmacy*, originally a kind of electuary, firſt deſcribed by Galen, compoſed of aloes, cinnamon, aſarabacca, ſpica nardi, ſaffron, and maſtic, made up with honey, or ſyrup of violets and honey.

It is denominated from the Geek ἱερὸς, *ſacer*, *holy*, becauſe of its rare virtues; and πικρὸς, *amarus*, *bitter*; aloes, which is the baſe thereof, rendering it extremely bitter.

It was uſed to purge and cleanſe the ſtomach, remove obſtructions, promote the menſes and hæmorrhoids, and ſweeten the blood; but its chief uſe among us is in powder, for making the tinctura ſacra.

Beſides this *ſimple* hiera picra, there is a *compound* ſort, called *diacolocynthidos Pachii*, becauſe colocynthis is the baſe thereof; and it was firſt uſed, with good ſucceſs, by Pachius of Antioch, in divers obſtinate diſeaſes. It is compoſed of colocynth, opopanax, ariſtolochia rotunda, agaric, and other ingredients. It is uſed in epilepſies, apoplexies, palſies, and lethargies; and to excite the menſes, and promote the expulſion of the after-birth.

There is alſo a third ſort of hiera, called *librans;* but rarely uſed. Dr. Quincy ſays, it is one of the moſt ridiculous medleys ever contrived. It paſſes for a cordial, &c.

Hiera picra, *Tincture of.* See Tinctura *Sacra.*

HIERAPOLIS, or Hieropolis, in *Ancient Geography*, a town of Phœnicia, in the Cyrrheſtic territory. Ptolemy.—Alſo, a town of Aſia, in Phrygia. Ptol. Steph. Byz. places it between Phrygia and Lydia, and ſays, that it had hot baths and ſeveral temples.—Alſo, a town of the iſland of Crete, which was epiſcopal.—Alſo, a town of Caria.—Alſo, an epiſcopal town of Arabia, under the metropolis of Babba, in the Moabitide territory.—Alſo, another epiſcopal town of Arabia, under the metropolis of Boſtra.—Alſo, a town of Aſia, in Syria, called "Bambyce" and now "Mambedj," S S.W. of Zeugma, at an equal diſtance from a chain of mountains and the Euphrates, or two days' journey N.E. of Aleppo. The worſhip of the great Syrian goddeſs, called "Atergatis," was eſtabliſhed in this town; but no traces now remain of her temple. The only remarkable monument is a ſubterraneous canal, which conducts the water from the mountains of the N. for the diſtance of four leagues. The name of Hierapolis ſtill ſubſiſts in that of another village, called "Yerabolos," ſituated on the Euphrates.

HIERAPUMNAL, in *Geography*, a town of Meckley; 60 miles S. of Munnipour.

HIERAPYTNA, in *Ancient Geography*, a town of Crete, called alſo "Cyrrha," "Pytna," and "Camyros," and ſuppoſed to be the ſame place which Ptolemy calls "Hiera Petra," or the Sacred Rock. The ruins of this city are ſtill viſible on the coaſt over-againſt the rocks called by the ancients the "Iſles of Aſſes." Hierapytna was one of the ſtrongeſt places on the iſland, when Metellus undertook the conqueſt of Crete; but it is at preſent only a village known by the name of "Girapietra."

HIERARCHY, Hierarchia, in *Theology*, the order or ſubordination among the ſeveral choirs or ranks of angels. The word is Greek ἱεραρχια, formed of ἱερος, *ſacer*, *holy*, and ἀρχη, *principatus*, *rule; q. d.* ἱερα αρχη, *holy command*, or *rule in holy things.*

St. Dionyſius, and other of the ancient writers, eſtabliſh nine choirs or orders of celeſtial ſpirits; *viz.* ſeraphim, cherubim, thrones, dominions, principalities, powers, virtues, angels, and archangels: and theſe they divide into three hierarchies.

Hierarchy is alſo uſed for the ſubordination between prelates and other eccleſiaſtics. See Priest, &c.

Archbiſhops, biſhops, prieſts and deacons, compoſe the hierarchy of the church of England. In that of Rome, the pope has likewiſe a place at the head of the hierarchy.

F. Cellot, a Jeſuit of Paris, has publiſhed a volume expreſs (De Hierarchia & Hierarchis) on the hierarchy, and thoſe who compoſe it. He there diſtinguiſhes a created and an uncreated hierarchy; a divine and a human, or eccleſiaſtical hierarchy; and in this, a hierarchy of juriſdiction, a hierarchy of an order, and a hierarchy of graces, the moſt ſublime of all.

He defines hierarchy, in the general, a command or ſovereignty in holy things; "principatus, ſive imperium, in rebus ſacris;" on which footing he holds, that hierarchy excludes all below biſhops; and that neither prieſts nor deacons can be reckoned among the number of hierarchiſts. Bellarmin, Hallier, Aurelius, &c. he holds, were all miſtaken, and did not diſtinguiſh between being *of* the hierarchy, and being *under* it.

HIERASSON, in *Ancient Geography*, an epiſcopal town of Arabia, under the metropolis of Beryra.

HIERATIC Paper, among the *Ancients*, was the fineſt ſort of paper, which was ſet apart only for ſacred or religious uſes. See Paper.

HIERATIN, in *Ancient Geography*, a town ſituated on the coaſt of the gulf of Perſia, at the mouth of a river named Heratemis.

HIERES, in *Geography*, a town of France, in the department of the Var, and chief place of a canton, in the diſtrict of Toulon; nine miles E. of Toulon. This town was formerly a ſea-port, where pilgrims bound for the holy land were accuſtomed to embark; but it is now at a conſiderable diſtance from the ſea; ſituated on the ſide of a hill, in a delightful country, where is a perpetual ſpring, and ſurrounded by beautiful gardens, affording the beſt fruit in France; oranges, citrons, and pomegranates grow in the open air. Near the town are large ſalt-works, in which the ſalt is made partly from ſea-water and partly from a ſalt-lake near the town. The noxious effects of the exhalations from the ſalt-lake have been remedied by a canal cut from the lake to the ſea. The gulf of Hières, between the town and the iſland ſo called, is a famous road for veſſels, with good anchoring ground and ſufficient depth of water. The place contains 6528, and the canton 6528 inhabitants, on a territory of 205 kiliometres in one commune. N. lat. 43° 7'. E. long. 6° 12'.

Hieres *Iſlands*, a cluſter of ſmall iſlands in the Mediterranean, near the coaſt of France, which take their name from the town of Hières. They are famous for a great variety of medicinal plants. N. lat. 43° 2'. E. long. 6° 10'.

HIERISOS, a town of European Turkey, in Macedonia, near the coaſt; 50 miles S.E. of Saloniki.

HIERKEN, a town of Norway, in the dioceſe of Drontheim; 40 miles S.E. of Romſdal.

HIERO, in *Biography*, king of Syracuſe, ſucceeded his brother Gelon in the year B. C. 478. Being of a jealous and tyrannical diſpoſition, his brother, who fell under his ſuſpicions, fled to the court of Theron, king of Agrigentum. A war between the two monarchs was the conſequence, which continued with various ſucceſs ſeveral years, till it was ended by a treaty advantageous to Hiero, who married the ſiſter of Theron, and then admitted his brother to favour. After a reign of no great length this prince fell into a lingering malady, the pains of which he endeavoured to divert by the converſation of poets and philoſophers, whom he had drawn to his court by liberal encouragement. He died about the year 467 B. C. Pindar addreſſed four of his odes to Hiero, who was a ſucceſsful competitor in the Olympic and Pythian games. Simonides was induced in his old age, to comply with an invitation of this prince; and it was his queſtion "What is God?" which produced the philoſopher's celebrated requeſt of time repeatedly doubled, for anſwering a query which ſeemed more difficult the more it was conſidered. Æſchylus, and other great men and poets, are mentioned as ornaments of his literary and ſocial circles. Univer. Hiſt. Bayle.

Hiero II. king of Syracuſe, was ſon of Hierocles, a deſcendant of Gelon. His mother was a female ſlave, and the father was ſo aſhamed of his offspring, that he is ſaid to have ordered him to be expoſed in the woods, where he was caſually nouriſhed with wild honey. His eſcape from the fangs of death was regarded as little ſhort of a miracle, and he was on that account brought home and very carefully educated. He ſoon became diſtinguiſhed among his companions, as well by his dexterity in all manly exerciſes, as by his readineſs in receiving inſtruction. As a warrior he ſerved in his youth under Pyrrhus king of Epirus, and at the age of twenty-five he was regarded as one of the ableſt commanders of his army. On the departure of Pyrrhus from Sicily, Syracuſe became a prey to the factious. Hiero, at the head of his men, entered the city with his colleague, and aſſumed the reins of government. To ſtrengthen his intereſt among the people he married the daughter of Leptines, a perſon of great authority, and committed the domeſtic management to his father-in-law, while he was abſent in the field. There were at this time large bodies of mercenaries in pay, whoſe inſolent and mutinous ſpirit was the ſource of conſtant diſturbances. Hiero freed himſelf from theſe by a ſtratagem which was more ſucceſsful than honourable. Leading the whole army againſt the Mamertines, a ferocious body of adventurers who had ſeized upon Meſſana, he formed two ſeparate diviſions of the mercenaries and Syracuſans, and ordered the former to attack the enemy, pretending that he meant to ſupport them with the latter. They entered on the conteſt with the utmoſt degree of valour, and were in the end almoſt entirely cut to pieces. When Hiero ſaw that he had nothing now to fear from his allies, he ſupplied their places with the Syracuſan military, who without difficulty gave the Mamertines a ſignal defeat, and made himſelf maſter of the ſurrounding country. On account of this ſucceſs he was unanimouſly raiſed to the throne of Syracuſe about the year 265 B. C. In a ſhort time he offered terms of peace and alliance with the Romans, which were readily accepted; and he ever after continued the ſteadieſt of all the foreign friends of the republic, and as a reward of his conſtancy he enjoyed a long and proſperous reign of almoſt uninterrupted tranquillity. His mild and equitable rule extinguiſhed party animoſities among his people, while his attention to the intereſts of agriculture enabled him to patronize all the arts by which a nation is made flouriſhing. He undertook, and with the aid of Archimedes accompliſhed, ſome public works of great magnificence. He encouraged commerce, and fitted out numerous fleets of trading veſſels to convey the ſuperfluous harveſts of Sicily to other countries, and, it is ſaid, that the commercial ſpirit of Hiero was fully allied to the liberality of princely opulence. He relieved the Rhodians, after a moſt diſaſtrous earthquake, with a hundred talents in money, and many other valuable donations. After the fatal battle of Thraſymenus, in the ſecond Punic war, he ſent a fleet laden with proviſions to the port of Oſtia, and directed his ambaſſadors, after condolences expreſſed in the moſt pathetic terms, to offer to the republic theſe and whatever other ſupplies it might ſtand in need of; and alſo for the ſake of the Augury to accept of a ſtatue of Victory of pure gold, weighing three hundred pounds. The ſenate was highly gratified with this mark of attachment at ſuch a period, and decreed that the Victory ſhould be placed in the temple of the Capitoline Jupiter. Hiero, notwithſtanding his zeal for the cauſe of the republic, was mortified by the conduct of his ſon Gelon, who openly declared for the Carthaginians, and by his influence would probably have obliged his aged father to a paſſive acquieſcence in his meaſures, had he not been carried off by a ſudden illneſs. Hiero died about the year 215 B. C., in the 90th year of his age, and the 54th of his reign. He was univerſally regretted, and all the inhabitants of Sicily ſhowed by their lamentations, that they had loſt a common father and an affectionate friend. He was a liberal patron of literature, and wrote a book on agriculture.

Hiero. See Ferro.

Hiero's *Crown*, in *Hydroſtatics*. The hiſtory of this crown and of the important hydroſtatical propoſition, to the diſcovery of which it gave occaſion, is as follows: Hiero, king of Syracuſe, having furniſhed a workman with a quantity of gold for making a crown, ſuſpected that he had been cheated, and that the workman had uſed a greater alloy of ſilver than was neceſſary in the manufacture of it; he, therefore, applied to Archimedes for a diſcovery of the fraud. This celebrated mathematician was led by chance to a method of detecting the impoſture, and of determining preciſely the quantities of gold and ſilver of which the crown was compoſed; for he obſerved, whilſt he was bathing in a tub of cold water, that as he immerged his body in it, the water ran out; and he immediately concluded, that the water which ran out, when his whole body was immerged, was equal in bulk to his body. It is ſaid, that he was ſo pleaſed with the diſcovery, as to run about naked crying out, εὕρηκα, εὕρηκα, *I have found it;* and others affirm, that he offered a hecatomb to Jupiter for having inſpired him with the thought.

On this principle he procured a ball of gold and another of ſilver, exactly of the weight of the crown, conſidering, that if the crown were altogether of gold, the ball of gold would be of the ſame bulk as the crown, and when immerſed in water, would raiſe the water juſt as high as the crown immerſed; but if it were wholly of ſilver, the ball of ſilver, being immerſed, would raiſe the water no higher than the crown immerſed; and if the crown was of gold and ſilver mixed in a certain proportion, this proportion would be diſcovered by the height to which the crown would raiſe the water higher than the gold and lower than the ſilver. Accordingly, let A M L B (*Plate* VIII. *Hydraulics, fig.* 3.) be a veſſel filled with water to the height D C, and let the maſs of gold, equal in weight to the crown, on being immerſed into the water raiſe the ſurface of it to E, and the maſs of ſilver raiſe it to G; then if the height of the veſſel above D C be divided into equal parts, and D F = 11, and D G = 19, it is plain the bulks of gold and ſilver will be as D F to D G, and the ſpecific gravities in the inverſe proportion of theſe quantities, or as D G to D F. If the crown be immerſed, it will raiſe the ſurface of water to E; whence the proportion of the bulks of the gold and ſilver in the crown may be determined. For ſince the difference of the ſpecific gravities of the gold and ſilver is D G = D F = F G = 8, if the bulk of the crown is divided into eight equal parts, it is evident, that ſince the ſpecific gravities of the debaſed and pure gold crowns will be as the bulks inverſely, that is, as D F to D E, we can eaſily find the point H, which will expreſs the ſpecific gravities of the former; for D E : D F :: D G : D H. This point H always divides the difference F G into two parts G H, H E, which have the ſame proportion as the parts of ſilver in the crown to the parts of gold; for as the point E aſcends, the point H deſcends, and when E coincides with G, H falls upon E, and the crown becomes wholly ſilver; on the contrary, when E deſcends to F, and H aſcends to G, the crown becomes wholly gold; therefore, F H will be every where to H G as the parts of gold to the parts of ſilver.

ſilver in the crown. Conſequently, in the preſent caſe, becauſe the crown, when immerſed, raiſes the water to the height D E, and H is three diviſions below G, it ſhews that three of the eight parts of the crown are ſilver, and the other five parts gold, as H is five of the diviſions above F. Hence, the bulk of the gold in the crown is to that of the ſilver as 5 to 3. In ſome ſuch method as this Archimedes deduced his propoſition, *viz.* that the difference of the ſpecific gravities of the compound and lighter ingredient, *i. e.* 5, (ſuppoſing the ſpecific gravity of gold to ſilver as 19 to 11, and the ſpecific gravity of the king's crown to be 16,) is to the difference of the ſpecific gravities of the heavier ingredient and the compound, *i. e.* 3, as the bulk of gold to that of ſilver made uſe of: ſo that if the whole crown were divided into eight parts, the gold would conſiſt of five, and the ſilver of three; and the magnitudes 5 and 3, multiplied by the ſpecific gravities 19 and 11 reſpectively, will give the numbers 95 and 33, expreſſing the proportion of the weight of the gold to that of the ſilver.

This propoſition of Archimedes may be demonſtrated analytically in the following manner: let the magnitudes of the gold and ſilver in the crown be A and B, and their ſpecific gravities as a and b; then ſince the abſolute gravity of any body is compounded of its magnitude and ſpecific gravity, the weight of the gold is $a\,A$, of the ſilver $b\,B$, and of the crown $a\,A + b\,B = c \times \overline{A + B}$, ſuppoſing c to be the ſpecific gravity of the mixture. Hence $a\,A - c\,A = c\,B - b\,B$; and conſequently, $c - b : a - c :: A : B$, as before. Cotes's Hydroſtatical, &c. Lectures, p. 81. Martin's Phil. Brit. vol. i. p. 305, &c. See *Specific* GRAVITY and EQUATION.

HIEROBOTANE, in *Botany*. See VERVAIN.

HIEROBULUM, a name given by the ancients to the colchicum.

Some have wondered that the medical writers of thoſe times ſhould give this name, which ſignifies the *ſacred root*, to a thing that was generally allowed to be a poiſon; but Wedelius has proved that it may be given, under proper regulations, with ſafety and great ſucceſs, in malignant and petechial fevers, and in the worſt kinds of the ſmall-pox and meaſles. The manner he gave it was in a mixture with bezoar and plantane-root, and this he called his *arcanum duplicatum catholicum*, or peſtilential alexipharmic. The ancients had a cuſtom of wearing this root about their necks, by way of an amulet, to prevent infection; and it was probably from this that it obtained the name of the ſacred bulb.

HIEROCERYCE, in *Mythology*, the chief of the ſacred heralds in the myſteries of Ceres, whoſe office was to exclude all improper perſons, to preſerve order in the celebration of theſe myſteries, and to recite the formulæ of initiation.

The hierocerycе repreſented Mercury, and was diſtinguiſhed by the ſame attributes; the office was perpetual, and belonged to the family of the Ceryces, the deſcendants of Ceryx, the laſt ſon of Eumolpus.

HIEROCHLOE, in *Botany*, from ἱερος, *ſacred*, and χλοη, *a green herb or graſs*, ſo named by Gmelin, becauſe this graſs has a ſimilar appellation in Pruſſia, and is there ſtrewed before the church-doors on feſtival days, being conſidered as ſacred to the Virgin Mary. Loeſel calls it *Gramen Mariæ*. Its ſcent, when it begins to dry, is that of Woodruff, or the moſt fragrant new hay.—Gmel. Sib. v. 1. 101. Brown. Prodr. Nov. Holl. v. 1. 208. (Diſarrhenum; Billard. Nov. Holl. v. 2. 82. See DISARRHENUM.)—Claſs and order, *Triandria Digynia.* Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two valves, containing three florets; its valves ovate, acute, membranous, unequal. *Cor.* of two valves; the outer ovate, coriaceous, ribbed, often rough, ſometimes ſhortly awned; the inner ſmaller, membranous, naked, emarginate, with inflexed edges. *Stam.* Filaments three in each of the lateral florets, capillary, recurved, ſhorter than the corolla, two in the central or terminal one; anthers pendulous, linear, forked at each end. *Piſt.* in the central floret only; Germen ſuperior, ovate, ſmall; ſtyles ſhort, approximated; ſtigmas longer than the corolla, linear, downy. *Peric.* none, except the permanent corolla. *Seed* ſolitary, ovate, pointed, ſmall, not attached to the corolla.

Eſſ. Ch. Calyx of two valves, containing three florets; the lateral ones male, with three ſtamens; central one hermaphrodite, with two. Corolla of two valves.

A genus of ſmooth graſſes, which in drying acquire the ſweet ſcent of Woodruff, or new hay, approaching to the bitter-almond flavour. The flowers are panicled; their central floret moſtly without awns, the lateral ones often awned. It contains many ſpecies, according to Mr. Brown, natives of the colder parts of both hemiſpheres.—Examples of *Hierochloe* are

H. *antarctica*. Brown 209. (Diſarrhenum antarcticum; Billard. Nov. Holl. v. 2. 83. t. 232.)—Panicle looſe, ſomewhat drooping. Glumes ſingle-ribbed, with an even keel. Lateral florets awned, downy, fringed at the margin and keel with curved hairs; central one pointed. Leaves flat.—Native of Van Diemen's Land.—Mr. Brown remarks, that *Holcus redolens*, Fort. Prodr. 92. n. 563, taken by that author from Solander's manuſcripts, appears by the Bankſian herbarium to be very nearly related to the above, differing only in having the inner glume of the calyx furniſhed with three ribs at the baſe, and the hairs which fringe the edges and keel of the lateral florets longer and ſtraighter. This was found in New Zealand, and we preſume it may ſafely be deemed a variety only. *Aira antarctica*, Forſt. Prodr. 8. n. 41, ſuſpected by La Billardière to be his *Diſarrhenum antarcticum*, is found by Mr. Brown, on examining an authentic ſpecimen, to be very different, and to belong to the genus *Avena*.

H. *redolens*. (Holcus redolens; Vahl. Symb. faſc. 2. 102.) Panicle cloſe. Keels of the glumes beſet with little ſcattered teeth. Florets bearded at the baſe; fringed at the margin and ſummit. Leaves involute.—Native of Terra del Fuego. Rather larger than the foregoing, with awns as long as the *corolla*, whoſe edges are ſtrongly fringed, and its extremity abrupt. The colour of the *corolla* is a rich brown; that of the *calyx* paler but not quite white.

Other ſpecies are the *Holcus borealis* and *auſtralis* of Schrader's Fl. Germ. v. 1. 252, 253, included by Linnæus in his *H. odoratus*, Sp. Pl. 1485; and *H. alpinus*, ſent us by Dr. Swartz as deſcribed by himſelf in Schrader's Journal, but we have not been able to diſcover it in the volumes we poſſeſs. This laſt has a ſmall, denſe, ovate, copper-coloured panicle, awns nearly equal to the corolla, and involute leaves. Not having acceſs to the whole of the ſpecies of which we have incomplete information, we cannot ſafely attempt to define even thoſe that we know, becauſe we cannot contraſt the whole together.

HIEROCLES, in *Biography*, governor of Bithynia and præfect of Alexandria, flouriſhed about the year 303, and diſtinguiſhed himſelf as an adverſary and perſecutor of the Chriſtians. He was a man of letters, and wrote "Two Books," addreſſed "To the Chriſtians," of which Lactantius has given an account (Inſt. l. v.), and which have been anſwered by Euſebius of Cæſarea. (Cont. Hier. ad Calc. em.

Evangel.) In theſe books Hierocles endeavoured to ſhew, that the ſacred ſcriptures abound with inconſiſtencies and contradictions. He alſo reviled Peter and Paul, and the other diſciples, as men ignorant and illiterate, ſome of whom got their livelihood by fiſhing, and propagators of falſehood. He alſo affirms, that Chriſt was baniſhed by the Jews, and afterwards aſſembled a band of 900 men and committed robbery. We are alſo informed, that Hierocles made a compariſon of Chriſt with Apollonius of Tyana, giving the preference to the latter. From the account of the work of Hierocles, which is given by Lactantius and Euſebius, Dr. Lardner deduces the following concluſions: that Hierocles had read the ſcriptures of the New Teſtament, if not of the Old likewiſe; that he bears teſtimony to the exiſtence of the ſeveral parts of the New Teſtament, the Goſpels, and the Epiſtles; that he did not diſpute the genuineneſs or antiquity of the writings of our apoſtles and evangeliſts, but merely endeavoured to diſparage them; that he did not deny the truth of our Saviour's miracles, but endeavoured to depreciate them by aſcribing them to magical arts; that the reſpect ſhewn to Jeſus by vaſt numbers of men, though he was defamed by many, and though he was crucified, is a demonſtration, that he was not a man of a bad character, for robbers and other malefactors, who ſuffer for their crimes, are never deified nor much reſpected after their death; it appears alſo, that Hierocles was the firſt who had formed a compariſon of our Saviour with Apollonius. Lardner's Works, vol. viii.

Hierocles, a Platonic philoſopher of Alexandria, flouriſhed about A. D. 450. He was cruelly ſcourged at Conſtantinople for his adherence to the Pagan ſuperſtitions; and it is ſaid that, in the midſt of his torture, when he received ſome of the blood into his own hand, he threw it upon the face of his judge, repeating the following verſe from Homer (Odyſſ. l. ix. v. 347.):

Κυκλωψ, τῆ, πίε οἶνον, ἐπει φάγες ἀνδρόμεα κρεα.

"Cyclops! ſince human fleſh has been thy feaſt,
Now drain this goblet, potent to digeſt."—Pope.

It appears, however, that notwithſtanding this unjuſt treatment by the Chriſtians at Conſtantinople, he afterwards philoſophized at Alexandria in his uſual manner; and hence we may infer, that the ſeverities with which the Gentile people, and particularly their learned men and philoſophers, were treated, were not extremely rigorous. Hierocles wrote a treatiſe "On Providence," of which Photius has given large extracts, and in which he appears to be an advocate for the Eclectic philoſophy, labouring to reconcile the doctrines of Plato and Ariſtotle concerning providence, the origin of the world, the immortality of the ſoul, and other ſubjects. He purſues the ſame method of philoſophizing in his book "On Fate," and in his "Commentary on the Golden Verſes of Pythagoras," which is ſtill extant. Beſides theſe, there are large fragments of other works preſerved in Stobæus, and generally publiſhed together with the works above-mentioned. All theſe are valuable, tending to recommend and promote virtue; but not with that force which flows from revelation, enjoining every part of moral righteouſneſs by divine authority, and with the aſſurance of recompences in a future ſtate. Lardner's Works, vol. ix. Brucker's Hiſt. Phil. by Enfield, vol. ii.

HIEROCORACES, *q. d. ſacred crows*, in *Mythology*, were miniſters of Mithras, or of the Sun, which the Perſians worſhipped under this title.

HIEROGLYPHIC, Ἱερογλυφικα, a ſymbol or myſtic figure, uſed among the ancient Egyptians to cover or conceal the ſecrets of their theology.

The word is compoſed of the Greek ἱερος, *ſacer, holy*, and γλυφειν, *ſculpere, to engrave*; it being the cuſtom to have the walls, doors, &c. of their temples, obeliſks, &c. engraven with ſuch figures.

Hieroglyphics are properly emblems or ſigns of divine, ſacred, or ſupernatural things; by which they are diſtinguiſhed from common ſymbols, which are ſigns of ſenſible and natural things.

Hermes Triſmegiſtus is commonly eſteemed the inventor of hieroglyphics; he firſt introduced them into the Heathen theology; from whence they have been tranſplanted into the Jewiſh and Chriſtian. See Hermes.

Sacred things, ſays Hippocrates, ſhould only be communicated to ſacred perſons. Hence it was, that the ancient Egyptians communicated to none but their kings and prieſts, and thoſe who were to ſucceed to the prieſthood and the crown, the ſecrets of nature, and the ſecrets of their morality and hiſtory; and this they did by a kind of cabbala, which, at the ſame time that it inſtructed them, only amuſed the reſt of the people. Hence the uſe of hieroglyphics, or myſtic figures, to veil their morality, politics, &c. from profane eyes. (Spon.) This author, it may be obſerved, and many others, do not keep to the preciſe character of a hieroglyphic, but apply it to profane as well as divine things.

Hieroglyphics are a kind of real characters, which do not only denote, but in ſome meaſure expreſs the things. Thus, according to Clemens Alexandrinus, Strom. v. a lion is the hieroglyphic of ſtrength and fortitude; a bullock, of agriculture; a horſe, of liberty; a ſphinx, of ſubtility, &c.

Such is the opinion that has generally been embraced both by ancient and modern writers, of the origin and uſe of hieroglyphics; it has been almoſt uniformly maintained that they were invented by the Egyptian prieſts, in order to conceal their wiſdom from the knowledge of the vulgar. But the late biſhop Warburton hath, with much ingenuity and learning, endeavoured to ſhew, that this account is erroneous.

According to this writer, the firſt kind of hieroglyphics were mere pictures; becauſe the moſt natural way of communicating our conceptions by marks or figures was by tracing out the images of things; and this is actually verified in the caſe of the Mexicans, whoſe only method of writing their laws and hiſtory was by this picture-writing. But the hieroglyphics invented by the Egyptians, were an improvement on this rude and inconvenient eſſay towards writing; for they contrived to make them both pictures and characters; in order to effect this improvement, they were obliged to proceed gradually, by firſt making the principal circumſtance of the ſubject ſtand for the whole, as in the hieroglyphics of Horapollo, which repreſent a battle of two armies in array by two hands, one holding a ſhield, and the other a bow; then putting the inſtrument of the thing, whether real, or metaphorical, for the thing itſelf, as an eye and ſceptre to repreſent a monarch, a ſhip and pilot the governor of the univerſe, &c. and finally, by making one thing ſtand for or repreſent another, where their obſervations of nature or traditional ſuperſtitions led them to diſcover or imagine any reſemblance; thus, the univerſe was deſigned by a ſerpent in a circle, whoſe variegated ſpots denoted the ſtars; and a man who had nobly ſurmounted his misfortune was repreſented by the ſkin of the hyæna, becauſe this was ſuppoſed to furniſh an invulnerable defence in battle.

The Chineſe writing, he obſerves, was the next kind of improvement in the uſe of hieroglyphics; the Egyptians joined characteriſtic marks to images, the Chineſe threw out the images, and retained only the contracted marks, and from theſe marks proceeded letters. The general concurrence of different people in this method of recording their thoughts, can never be ſuppoſed to be the effect of imitation, ſiniſter views, or chance; but muſt be conſidered as the uniform voice of nature, ſpeaking to the rude conceptions of mankind; for not only the Chineſe of the Eaſt, the Mexicans of the Weſt, and the Egyptians of the South, but the Scythians, likewiſe, of the North, and the intermediate inhabitants of the earth, *viz.* the Indians, Phœnicians, Ethiopians, &c. uſed the ſame way of writing by picture and hieroglyphic.

The biſhop farther ſhews, that the ſeveral ſpecies of hieroglyphic writing took their riſe from nature and neceſſity, and not from choice and artifice, by tracing at large the origin and progreſs of the art of ſpeech. He proceeds to ſhew how, in proceſs of time, the Egyptian hieroglyphics came to be employed for the vehicle of myſtery. They uſed their hieroglyphics two ways; the one more ſimple, by putting the part for the whole, which was the *curiologic* hieroglyphic; and the other more artificial, by putting one thing, of reſembling qualities, for another, called the *tropical* hieroglyphic; thus the moon was ſometimes repreſented by a half circle, and ſometimes by a cynocephalus. They employed their proper hieroglyphics to record openly and plainly, their laws, policies, public morals, and hiſtory, and all kinds of civil matters; this is evident from their obeliſks, which were full of hieroglyphic characters deſigned to record ſingular events, memorable actions, and new inventions; and alſo from the celebrated inſcription of the temple of Minerva at Sais, where an infant, an old man, a hawk, a fiſh, and a river-horſe, expreſſed this moral ſentence; All you who come into the world and go out of it know this, that the gods hate impudence. However, the tropical hieroglyphics, which were employed to divulge, gradually produced ſymbols which were deſigned to ſecrete or conceal; thus Egypt was ſometimes expreſſed by the crocodile, ſometimes by a burning cenſer with a heart upon it; where the ſimplicity of the firſt repreſentation and the abſtruſeneſs of the latter ſhew, that the one was a tropical hieroglyphic for communication, and the other a tropical ſymbol invented for ſecrecy.

Enigmatic ſymbols were afterwards formed by the aſſemblage of different things, or of their properties that were leſs known; and though they might have been intelligible at firſt, yet, when the art of writing was invented, hieroglyphics were more generally diſuſed, the people forgot the ſignification of them, and the prieſts, retaining and cultivating the knowledge of them, becauſe they were the repoſitories of their learning and hiſtory, at length applied them to the purpoſe of preſerving the ſecrets of their religion.

Symbols were the true original of animal worſhip in Egypt, as ſir John Marſham conjectured, Can. Cron. p. 58. becauſe in theſe hieroglyphics was recorded the hiſtory of their greater deities, their kings, and lawgivers; repreſented by animals and other creatures; the ſymbol of each god was well known and familiar to his worſhippers, by means of the popular paintings and engravings on their temples, and other ſacred monuments; ſo that the ſymbol preſenting the idea of the god, and that idea exciting ſentiments of religion, it was natural for them in their addreſſes to any particular god, to turn to his repreſentative mark or ſymbol; eſpecially when we conſider farther, that the Egyptian prieſts feigned a divine original for hieroglyphic characters, in order to increaſe the veneration of the people for them. Theſe would of courſe bring on a relative devotion to theſe ſymbolic figures, which, when it came to be paid to the living animal, would ſoon terminate in an ultimate worſhip.

Another conſequence of the ſacredneſs of the hieroglyphic characters was, that it diſpoſed the more ſuperſtitious to engrave them on gems, and wear them as amulets or charms. This magical abuſe ſeems not to have been much earlier than the eſtabliſhed worſhip of the god Serapis, which happened under the Ptolemys, and was firſt brought to the general knowledge of the world by certain Chriſtian heretics and natives of Egypt, who had mixed a number of Pagan ſuperſtitions with their Chriſtianity. Theſe gems, called abraxas, are frequently to be met with in the cabinets of the curious, and are engraven with all kinds of hieroglyphic characters. To theſe abraxas ſucceed the taliſmans. Warburton's Divine Legation of Moſes demonſtrated, vol. ii. paſſim.

HIEROGRAMMATEI, 'Ιερογραμματεις, among the *Ancient Egyptians*, were the prieſts appointed to explain myſteries of religion, and to direct the performance of the ceremonies thereof; and for this purpoſe they had a kind of ſacred alphabetical character, different from the political one, and which the writer, cited in the laſt article, conſiders as one of the four kinds of Egyptian writing. This, as well as the epiſtolic, uſed in civil matters, was formed by the letters of an alphabet; and, from its being uſed only in religious matters, was called hierogrammatic. The other two ſpecies of writing were the hieroglyphic and ſymbolic.

The hierogrammatei invented and wrote hieroglyphics and hieroglyphical books, and occaſionally explained them, together with other matters relating to the doctrines of religion. If we may believe Suidas, they were all prophets; at leaſt, he relates, that a hierogrammateus foretold to an ancient king of Egypt, that there would be an Iſraelite of great wiſdom, virtue, and renown, who ſhould humble Egypt.

The hierogrammatei were always near the king, to aſſiſt him with their informations and councils: the better to fit them for this, they made uſe of the ſkill and knowledge they had acquired in the ſtars and the motions of the heavenly lights, and even of the writings of their predeceſſors, wherein their functions and duties were delivered. They were exempted from all civil employments, were reputed the firſt perſons in dignity next the king, and bore a kind of ſceptre in form of a plough-ſhare.

After Egypt became a province of the Roman empire, the hierogrammatei ſunk into neglect.

HIEROLOGY, denotes a diſcourſe on ſacred things. Among the Jews and Greeks, this term was uſed for the nuptial benediction.

HIEROMANTIA, 'Ιερομαντεια, in *Antiquity*, a general name for all kinds of divination, made from the various things offered in ſacrifice to the gods. They firſt made conjectures from the external parts and motions of the victim; then from its entrails, from the flame in which it was conſumed, from the cakes and flour, from the wine and water, &c. Vide Pott. Archæol. Græc. lib. ii. cap. 14. tom. i. p. 314.

HIEROMENIA, 'Ιερομηνια, in *Ancient Chronology*, a name given to the month in which the Nemean games were celebrated. It was the ſame with the Athenian month Bœdromion, and anſwered to the latter end of our Auguſt and beginning of September.

HIEROMNEMON, 'Ιερομνημων, among the *Ancient Greeks*, ſignified a delegate choſen by lot, and ſent to the great council of the Amphictyons, where he was to take care of what concerned religion. The hieromnemones were reckoned more honourable than the other members of that aſſembly, the general meetings of which were always ſummoned by them, and their names were prefixed to the decrees made by that council.

Hieromnemon, compoſed of ἱερος, *ſacred*, and μνημων, *one who advertiſes* or *puts in mind of*, an officer in the ancient Greek church, whoſe principal function was to ſtand behind the patriarch at the ſacraments, ceremonies, &c. and ſhew him the prayers, pſalms, &c. which he was to rehearſe.

He alſo clothed the patriarch in his pontifical robes, and aſſigned the places of all thoſe who had a right to be around him when ſeated on his throne, as the maſter of the ceremonies now does to the pope.

The hieromnemon was commonly a deacon: when he was in prieſt's orders, as it ſometimes happened, he was excuſed from dreſſing the patriarch in his pontifical habits. Whether he were deacon or prieſt, he had always under him an officer named *caſtricius*. He had alſo the keeping of the book entitled "Contacion," or book of ordination; and that called the Enthronianiſmus, which was a ſort of ritual.

Hieromnemon, in the *Writings of the Ancients*, was alſo the name of a ſtone ſaid to have been uſed in divination, and called by others crotylos and amphicome. There is no deſcription left us of it by the ancients, from which we may gueſs what ſtone it was, or from whence it was brought.

HIERONESOS, in *Ancient Geography*, an iſland of the Mediterranean, between Sicily and Africa. Pliny.

HIERONYMITES, compounded of ἱερος, *holy*, and ονομα, *name*, or *Hermits of St. Jerom*. See Jeronymites.

HIEROPHANTES, or Hierophanta, from ἱερος, *holy*, and φαινω, *I appear*, in *Antiquity*, a prieſt among the Athenians.

The hierophantes was properly the chief perſon that officiated in the Eleuſinia, that great ſolemnity ſacred to Ceres.

This office was firſt executed by Eumolpus, and continued in his family for twelve hundred years, though, when any perſon was appointed to this dignity, he was required always to live in celibacy.

St. Jerom ſays, that the hierophantes extinguiſhed the fire of luſt, by drinking cicuta, or the juice of hemlock, or even by making themſelves eunuchs. Apollodorus obſerves, that the hierophantes inſtructed perſons initiated into their religion in the myſteries and duties thereof, and that it was hence he derived his name: for the ſame reaſon he was called *prophetes*, the prophet. He had officers under him to do the ſame thing, or to aſſiſt him therein, who were alſo called *prophetes* and *exegetæ*, i. e. *explainers of divine things*.

To the hierophantes it belonged to dreſs and adorn the ſtatues of the gods, and to bear them in proceſſions and ſolemn ceremonies.

There were alſo women employed in the ceremonies of the Eleuſinia, and named Hierophantida.

HIEROPHYLAX, of ἱερος, *ſacred*, and φυλαξ, *keeper*, of φυλαττω, *I keep*, an officer in the Greek church. His function is that of guardian or keeper of the holy things, utenſils, veſtments, &c. anſwering to our *ſacriſta* or *ſexton*.

HIEROSCOPY, Hieroscopia, formed of ἱερος, *ſacred*, and σκοπεω, *I view* or *conſider*, a kind of divination performed by conſidering the victim, and obſerving every thing that occurs during the courſe of the ſacrifice.

HIERSAC, in *Geography*, a town of France, in the department of the Charente, and chief place of a canton, in the diſtrict of Angoulême. The place contains 593, and the canton 11,113 inhabitants, on a territory of 205 kiliometres, in 14 communes.

HIERTING, or Ietting, a ſea-port of Denmark, ſituated at the mouth of the Warde, with one of the beſt harbours in N. Jutland; 22 miles N.W. of Ripen. N. lat. 55° 29′. E. long. 8° 22′.

HIERTLANDA, a town of Sweden, in the province of Smaland; 30 miles N. of Wexio.

HIETANIEMI, a town of Sweden, in Weſt Bothnia; 24 miles N. of Tornea.

HIGANQUET, a town on the E. coaſt of the iſland of Mindanao. N. lat. 9° 26′. E. long. 125° 51′.

HIGDEN, Ralph, in *Biography*, one of the Engliſh chroniclers, was a monk of St. Werburg's, in Cheſter, where he died in the year 1377. His hiſtorical work was entitled "Polychronicon," originally written in Latin, but tranſlated into Engliſh by John de Treviſa, and printed by Caxton. It is in ſeven books, and extends from the creation to the year 1357. This author is valuable as having preſerved ſeveral documents relative to the times of the ancient Britons and Saxons, from chronicles now loſt. The beſt edition is that of 1642, fol.

HIGH, Altus, a term of relation applied to a body, conſidered, according to its third dimenſion, or its elevation above the horizon, or even above the ground.

High is alſo uſed to denote a perſon in power, dignity, &c.

High *Chancellor, Lord*. See Chancellor.

High *Church*. See Church.

High-*Bearing Cock*. See Cock.

High *Commiſſion Court*. See Commission.

High *Conſtable of England*. See Constable.

High *Court of Parliament*. See Parliament.

High *and Dry* is a phraſe, among *Seamen*, denoting the ſituation of a ſhip when ſhe has run a-ground, ſo as to be ſeen dry upon the ſtrand.

High *Dutch* is the German tongue in its greateſt purity, as ſpoken in Miſnia, &c. See Teutonic, &c.

High, in *Muſic*, is ſometimes uſed in the ſame ſenſe with *local*, in oppoſition to *low*; and ſometimes in the ſame ſenſe with *acute*, in oppoſition to *grave*.

High *Operation*, in *Surgery*, is a method of extracting the ſtone; thus called, becauſe the ſtone is taken out at the upper part of the bladder.

For the method of performing the high operation, ſee Lithotomy.

The high operation is ſaid to have been firſt practiſed by Roſſetus: others ſay by Franco, a ſurgeon of Lauſanne. It was retrieved by Mr. Douglas, and practiſed with good ſucceſs by Mr. Cheſelden and others.

High-*Peak* of Derbyſhire, in *Geography*, has too often been mentioned as denoting ſome particular precipice, or frightfully rugged diſtrict, inſtead of being only one of the hundreds of the county, and including a great portion of well cultivated and populous tracts. What further ſhews this miſtake, as Mr. Farey obſerves in his "Report on Derbyſhire," is, that the Low Peak hundred, or wapentake of Wirkſworth, includes all the high and rugged lands on the weſt border of Derbyſhire, from Aſhbourn, almoſt to Whaley bridge, including Axe-edge, and others of its higheſt hills.

High *Places*. See Grove.

High *Point*, in *Geography*, a cape on the N. coaſt of the iſland of Barbadoes. N. lat. 13° 22′. W. long. 58° 30′.

High *Prieſt*. See Pontifex.

High *Relievo*. See Relievo.

High *Sea*, or ocean, is that far from land. See Sea.

High *Steward, Lord*. See Steward.

High *Taper*, in *Botany*. See Mullein.

High *Town*, in *Geography*, a town of America, in the ſtate of Georgia; 112 miles W. of Tugeloo.

HIGH *Tor*, at Matlock, is the name of a very high and perpendicular rock of lime-ſtone alternating with toad-ſtone, amygdaloid, or baſalt, cloſe on the E. ſide of the Derwent river, about ⅓d of a mile S.W. of Matlock church: a ſection of the ſtrata in this remarkable cliff may be found in the Philoſophical Magazine, vol. xxxi. plate 2.

HIGH *Treaſon*. See TREASON.

HIGH *Treaſurer, Lord*. See TREASURER.

HIGH *Water*, is that ſtate of the tides when they ceaſe to flow up, or the greateſt height of the flood-tide. See TIDE.

HIGH-*waved Cockle*, in *Natural Hiſtory*, is the name of a ſpecies of foſſil-ſhells, found in great numbers in the Bath free-ſtone, on King's Down, near Bath, along with other ſhells, called pundibs, and two other kinds. Mr. Walcott, in his petrifactions found near Bath, figure 30, repreſents this ſhell, and deſcribes it as having many ribs from the hinge to the hedges; beak-pointed; margin with a high wave: and ſays that it is common on the ploughed fields of ſome ſtone-brack ſoils.

HIGH-*Way*, *Via Regia*, a free paſſage for the king's ſubjects; on which account it is called the king's high-way though the freehold of the ſoil belongs to the lord of the manor, or the owner of the land. (2 Inſt. 705.) Thoſe ways that lead from one town to another, and ſuch as are drift or cart-ways, and are for all travellers in great roads, or that communicate with them, are high-ways only; and their reparation is under the care of ſurveyors. A nuiſance in a high-way is a common nuiſance, and puniſhable by indictment; but a way to a pariſh-church, or to the common fields of a town, or to a private-houſe, or, perhaps, to a village which terminates there, and is for the benefit of the particular inhabitants of ſuch pariſh, houſe, or village only, may be called a private-way, but not a high-way, becauſe it belongeth not to all the king's ſubjects, but only to ſome particular perſons, each of whom, as it ſeems, may have an action on the caſe for a nuiſance therein. (1 Hawk. 201.) So if I have a private way without a gate, and a gate is hung up, an action lies upon the caſe, for I have not my way as I had before. (Litt. R. 267.) So if one grants me a way, and afterwards digs trenches in it to my hindrance, I may fill them up again. (Godb. 53.) All private ways are to be repaired by thoſe who uſe them.

A river that is common to all men, is alſo called a high-way. 1 Hawk. 201.

Where a high-way lies within a pariſh, the pariſh is bound to repair it, unleſs it appears that the ſame ought to be repaired by ſome particular perſon, either by reaſon of tenure or preſcription. At common law it is ſaid that all the country ought to make good the reparations of a high-way, where no particular perſons are bound to do it, becauſe the whole country have their eaſe and paſſage by that way.

If a high-way leading through a field is out of repair, travellers may juſtify going out of the track, though there be corn ſowed; and in caſe a high-way is not ſufficient, any paſſenger may break down the incloſure, and go over the land adjoining, until a ſufficient way be made. All kinds of injuries to high-ways, that render them leſs commodious to travellers, are deemed nuiſances; ſuch as laying logs of timber in them, erecting gates, or making hedges acroſs them, permitting boughs of trees to hang over them, &c. By ſtat. 13 Geo III. cap. 78. no tree or buſh is to be allowed to grow or ſtand within fifteen feet of the centre of the high-way, on forfeiture of 10*s*. by the owner. The poſſeſſors of land next adjoining ſhall cut, prune, or plaſh their hedges, and lop trees growing in or near ſuch hedges, or be liable to a complaint of the ſurveyor, after ten days notice; and the juſtices at a ſpecial ſeſſions ſhall order ſuch hedges to be cut or plaſhed, and ſuch trees to be lopped; and the poſſeſſor, who refuſes to comply within ten days after notice of ſuch order, ſhall forfeit 2*s*. for every twenty-four feet in length of ſuch hedge, and 2*s*. for every tree; the ſurveyor ſhall order the ſame to be done, and the poſſeſſor, beſide the penalties, ſhall pay the charges of doing the ſame, to be levied by diſtreſs, by warrant of one juſtice. The occupiers of ſuch lands ſhall keep their ditches, drains, and water-courſes, in proper order, on forfeiture of 10*s*. after ten days notice given by the ſurveyor. No ſtone, timber, ſoil, or other matter, ſhall be laid in the high-way, ſo as to obſtruct or prejudice it, and remain there five days after notice by the ſurveyor, on forfeiture of 10*s*. and if ſuch ſtone, &c. ſhall be laid within fifteen feet of the centre of the high-way, the owner of the adjacent lands, after five days notice, may remove and diſpoſe of the ſame to his own uſe. Perſons making incroachments on the high-way by any fence, or breaking up the ſoil, within fifteen feet from its centre, ſhall forfeit 40*s*. to the informer, and the ſurveyor ſhall cauſe the damage to be repaired by the offender; and one juſtice may levy the penalty and expence by diſtreſs. The ſurveyor is required to give written notice to thoſe who offend in theſe reſpects; and if they do not comply within twenty days after ſuch notice, he ſhall proceed to remove nuiſances, &c. to cleanſe ditches, &c. and to cut hedges, &c. at the expence of the offender, who ſhall beſides forfeit for his neglect one penny for every foot in length. If the high-way is wilfully obſtructed by carriages or implements of huſbandry, the perſon offending ſhall forfeit 10*s*.

It is farther enacted by the ſame ſtatute, 13 Geo. III. cap. 78. that no driver of any cart, dray, or waggon, ſhall ride upon ſuch carriages, without having ſome perſon on foot to guide the ſame, excepting ſuch carriages as are conducted by perſons holding the reins of the horſe or horſes drawing them; or damage or obſtruct the paſſage of any perſon or carriage in the ſtreet or high-way, or quit the high-way, or wilfully be at ſuch a diſtance from his carriage, ſo that he cannot have the government of the horſes, &c. drawing the ſame; or refuſe or neglect to make way for loaded carriages; or drive a carriage not having the owner's name, and refuſe to diſcover it, under the penalty of forfeiting any ſum not exceeding 10*s*. if the driver be not the owner of the carriage; and if he be the owner, any ſum not exceeding 20*s*. on conviction by confeſſion, view of the juſtice, or oath of one witneſs, before one juſtice. Owners of carriages are alſo required to have their names and places of abode painted in large legible letters on ſome conſpicuous part; and the owner of every ſtage waggon, or cart, ſhall, moreover, have the following words, *common-ſtage waggon*, or *cart*, as the caſe may be, under the penalty of a forfeiture not exceeding 5*l*. nor leſs than 20*s*. And no ale-houſes ſhall be kept by toll-collectors at any public bridge, under a penalty of 5*l*.

It is alſo enacted by the ſame ſtatute, that the juſtices ſhall iſſue their precept to the ſurveyor, requiring him to erect poſts or ſtones in places where ſeveral high-ways meet, with inſcriptions on them in large legible letters, containing the names of the towns or chief villages to which the ſeveral ways lead; and alſo in places ſubject to floods, inſcribed with marks denoting the greateſt depth of the water: and if he ſhall neglect or refuſe for three months, he ſhall forfeit 20*s*. And if any perſons remove or deſtroy poſts, blocks, banks, &c. ſet up for the ſecurity of horſe and foot cauſeways, or the battlements of bridges, or deſtroy or even deface any mile-ſtone or direction poſt, they ſhall forfeit, on conviction on the oath of one witneſs, before one juſtice, or upon view of the juſtice, a ſum not exceeding 5*l.* nor leſs than 10*s.* and on default of payment be committed to the houſe of correction for any term not exceeding one month, nor leſs than ſeven days.

The ſame ſtatute farther enjoins, that no waggon, the fellies of whoſe wheels are nine inches broad, ſhall be drawn with more than eight horſes, nor carts of the ſame dimenſions with more than five horſes; and no waggon, the fellies of whoſe wheels are ſix inches broad, and rolling on each ſide a ſurface of nine inches, ſhall be drawn with more than ſeven horſes; and no waggon rolling a ſurface of ſix inches only, with more than ſix horſes: nor cart, the breadth of whoſe wheels is ſix inches, with more than four horſes; and no waggon, the fellies of whoſe wheels are of leſs breadth than ſix inches, ſhall be drawn with more than five horſes, nor cart of the ſame breadth with more than three horſes: the owner that offends againſt theſe regulations ſhall forfeit 5*l.* and the driver, not being the owner, 10*s.* for every horſe above the proper number, to the ſole uſe of the informer. But carriages moving upon wheels or rollers, of the breadth of ſixteen inches on each ſide with flat ſurfaces, ſhall be allowed to be drawn with any number of horſes. No regulations affecting the number of horſes, and wheels of carriages, ſhall extend to carriages uſed in carrying one ſtone or block of marble, cable rope, piece of metal, or piece of timber, or to ſuch ammunition and artillery as may be required for his majeſty's ſervice. For all the purpoſes of this act two oxen, or horned cattle, ſhall be conſidered as one horſe.

By the common law, no high-way can be changed without the king's licence firſt obtained, upon a writ of *ad quod damnum.* In aid of the common law, and to render the changing of high-ways leſs troubleſome and expenſive, power is given by 13 Geo. III. cap. 78. to the juſtices of the peace to widen, divert, and change high-ways, as they ſhall judge moſt convenient. And it is enacted that the ſurveyor ſhall make every public cart-way leading to any market town, twenty feet wide at the leaſt, and every public horſe-way or drift-way eight feet wide at the leaſt, wherever the ground between the fences ſhall admit of it; or on the view of two juſtices, it ſhall be widened or diverted at their pleaſure, provided that its breadth exceeds not thirty feet, and that no houſes or buildings are pulled down, or any garden, park, court, or yard, taken away; and the owners of the ground, which ſhall be laid into the high-way, or through which it ſhall paſs, ſhall be recompenſed for it, and every injury redreſſed. The expences of making, repairing, &c. high-ways, are defrayed by equal aſſeſſments, made by the warrant of a juſtice, at a ſpecial ſeſſions, on all occupiers of lands, tenements, woods, tithes, and hereditaments; provided that no ſuch aſſeſſment in one year ſhall exceed ſixpence in the pound. In extraordinary caſes another aſſeſſment may be made, provided this and the preceding ſhall not in any one year exceed the rate of nine-pence in the pound.

By the ſame ſtatute the juſtices are enjoined to hold a ſpecial ſeſſions for the high-ways, in the week next after the Michaelmas general quarter-ſeſſions yearly; and notice ſhall be given to the conſtables of the reſpective pariſhes at leaſt ten days before it ſhall be held. Surveyors of the high ways are to be choſen yearly out of a liſt of proper perſons, nominated by the houſholders, aſſeſſed to any parochial or public rate, by the juſtices at their ſeſſions; and their number ſhall depend on the extent of the pariſh, &c. But no perſon is liable to be appointed to ſerve this office within three years from the time of his having ſerved it, without his own conſent. Thoſe who refuſe to ſerve, after having been nominated by the pariſh and juſtices, ſhall forfeit 5*l.* and if they were only nominated by the juſtices, they ſhall forfeit 50*s.* In this caſe, the juſtices may appoint a proper perſon to this office, with a ſalary not exceeding one eighth part of what ſhall have been raiſed by aſſeſſment of ſix-pence in the pound for the uſe of the high-ways in the diſtrict where the aſſeſſment hath been raiſed; and they ſhall alſo appoint one ſubſtantial inhabitant of ſuch pariſh, &c. for aſſiſtant to ſuch ſurveyor, till the next annual appointment, whoſe refuſal incurs a forfeiture of 50*s.* And if a ſecond perſon refuſe, he ſhall alſo forfeit 50*s.* and a third ſhall be appointed, with a ſalary. Special ſurveyors returned to the juſtices by two parts out of three of thoſe who have the choice, with a ſettled ſalary, may be appointed by them with the ſaid ſalary. In caſe of the death of a ſurveyor, two juſtices at a ſpecial ſeſſions may appoint another in his room.

It is the buſineſs of the ſurveyor to preſerve high-ways in proper repair, &c. For this purpoſe it is enacted by the ſtatute (34 Geo. III. c. 74.), that every perſon keeping a team, draught, or plough, *i. e.* who keeps a waggon, cart, wain, plough, or tumbrel, and three or more horſes or beaſts of draught, ſhall ſix days in the year furniſh one wain, cart, or carriage, and other neceſſaries, and two able men, on the day and place appointed by the ſurveyor. Thoſe who occupy lands of 50*l.* a year ſhall do the ſame; and in like manner for every 50*l.* a year reſpectively. Thoſe who occupy lands under 50*l.* ſhall pay to the ſurveyor, in lieu of the duty, for every 20*s.* annual value of their land, &c. one penny for every day's ſtatute duty, &c. and the ſame for every 20*s.* above the annual value of 50*l.* and leſs than 100*l.* Perſons keeping a team, but occupying land of the yearly value of 30*l.* ſhall be obliged to ſend only one labourer with ſuch team. Perſons not keeping a team, but keeping one or more cart or carts, and one or more horſes, ſhall ſend one labourer with each cart; and perſons keeping a wheel-carriage, but no team, nor occupying 50*l.* a year, in the pariſh, townſhip, or place where he reſides, ſhall pay to the ſurveyor 1*s.* in reſpect of every day's ſtatute duty, for every horſe which he ſhall uſe in ſuch carriage. Every inhabitant eighteen years of age, and upwards, but under ſixty, nor chargeable in any other way for 4*l.* a year, or upwards, and not being an apprentice or menial ſervant, or not having ſerved or compounded in any other place for that year, ſhall go in perſon, or find a labourer, on each of the aforeſaid days. Carriages ſhall be changed, at the diſcretion of the ſurveyor, for men, three being allowed for each team, or 4*s.* 6*d.* ſhall be paid in lieu of them. Perſons liable to perform ſtatute duty may compound at ſuch rates as the juſtices ſhall think fit, not exceeding 6*s.* nor leſs than 3*s.* for each team, for each day, or, in default of their adjudging the ſame, the ſum of 4*s.* 6*d.*; for every cart and one horſe 2*s.*; for every cart with two horſes 3*s.* in lieu of each day's duty. And every inhabitant liable to perform ſuch duty, and not chargeable in any other reſpect, may compound for 4*d.* each day. The ſurveyor ſhall give four days notice to thoſe whoſe attendance is required, and they ſhall bring with them their own tools, continue at work for eight hours in each of the appointed days; and defaulters in finding a team, &c. ſhall forfeit 10*s.* thoſe in ſending a cart with one horſe and man, 3*s.* for not ſending a cart with two horſes and one man, 5*s.* and for each labourer 1*s.* 6*d.* Surveyors for neglect of duty, where no particular penalty is impoſed, ſhall forfeit a ſum

ſum not exceeding 5*l.* nor leſs than 10*s.* at the diſcretion of the juſtices. All defects of repairs of high-ways ſhall be preſented in the county where they lie: and the indictment muſt ſhew, that they are high-ways; alſo the places from and to which they lead: where the nuiſance was done, and how far it extends; it muſt likewiſe ſtate the fact clearly. Juſtices may preſent on their own view. For the farther regulations relating to high-ways, the principal of which have been already recounted, the reader is referred to 13 Geo. III. cap. 78.

HIGH-*ways, turnpike.* See TURNPIKE.

HIGH-*way men,* are robbers on the high-way; for the apprehending and taking of whom, a reward of 40*l.* is given by the ſtatute of 4 W. c. 8. to be paid within a month after conviction by the ſheriff of the county; to which the ſtatute 8 Geo. II. cap. 16. ſuperadds 10*l.* to be paid by the hundred indemnified by ſuch taking.

HIGHAM FERRERS, in *Geography,* a borough, market-town, and pariſh in the hundred of the ſame name, in the county of Northampton, England, is a place of conſiderable note, and is ſituated on a rocky elevation, abounding with ſprings, about half a mile from the northern banks of the Nen. Northward of the church, is a ſpace called the Caſtle-yard, the ſcite of a caſtle, which is ſuppoſed to have been erected by one of the Ferrer's family. But it more probably owes its origin to Thomas, earl of Lancaſter, ſon of Edmund, the younger ſon of Henry III.; who obtained this lordſhip in the fiftieth year of that monarch's reign. This nobleman, in the fifth of Edward II., was at the head of the aſſociation, which, under the pretext of ſupporting public liberty, demanded and obtained the diſmiſſal of Piers de Gaveſton, the royal favourite. The Caſtle-yard is divided into two parts, by a deep foſs, running from eaſt to weſt. That on the ſouth ſide contains about two acres: the only remains are hollows, heaps of ruins, and foundations of walls. The northern diviſion, both in extent and ſtrength, appears to have been the moſt conſiderable work. It comprizes nearly four acres, having on the eaſt ſide a very large moat, about fifty feet wide, and five hundred long; and another on the ſouth ſide of ſimilar dimenſions. This, it is conjectured, was the ſcite of the caſtle; and the ſpace to the ſouth, the ſituation of the advanced and covering works. The church is a handſome ſtructure: at the weſt end of the nave, on a handſome embattled tower, is raiſed a finely proportioned hexagonal ſpire; the weſtern front of the tower diſplays ſome curious architectural features; at the baſe is a pointed arched door-way, with two openings for doors beneath flattened arches: the ſurrounding jambs, pediment, &c. are charged with ſculpture of figures, foliage, &c. On each ſide of the chancel are ten ſtalls; one ornamented with a carved head of archbiſhop Chichele; another with his arms; the reſt with various enigmatical devices. In the chancel is an inſcription to the memory of the archbiſhop's parents. This prelate founded a college here in the year 1422, for eight ſecular canons. The building, now in a ruinous ſtate, was ſome years ſince converted into an inn: a portion of the revenues forms the endowment of the preſent free-ſchool. He alſo founded and endowed the Alms, or Bead-houſe, for twelve poor men and one woman.

Higham is a borough by preſcriptive right, and was incorporated in the reign of Philip and Mary. The corporation compriſes a mayor, ſeven aldermen, thirteen capital burgeſſes, and other inferior officers. The aldermen are choſen out of the burgeſſes; and the mayor annually elected from the body of aldermen. The mayor has a right of holding a court every three weeks, for determining actions for debt, in any ſum under forty pounds. The borough, by virtue of the ſame charter, returns one member to parliament; the elective franchiſe being veſted in all the inhabitants not receiving alms. The town is ſmall, conſiſting of two ſtreets, a lane, and what is here called the market-ſtead, in which ſtands a croſs, bearing a cube at the top, and on the four ſides are carved in ſtone different figures, emblematic of the crucifixion. By the returns under the population act, the number of houſes is 125; of inhabitants, 726. From its formerly having had three weekly markets, it was probably then much more populous. Thoſe kept on Mondays and Thurſdays have long been diſuſed, and the one held on Saturday is much decayed; though here are ſtill ſeven well accuſtomed fairs. The diſtance from London is 64 miles. Higham is particularly noted as the birth place of Henry Chichele, who was archbiſhop of Canterbury in the reigns of Henry V. and VI.; of whoſe love of learning and liberal encouragement for its diffuſion, the noble inſtitutions he founded and endowed are ſtrong and laſting monuments. Bridges's Hiſtory of Northamptonſhire, 2 vols. fol.

HIGHGATE, a populous hamlet, principally in the pariſh of Hornſey, and hundred of Oſſulſton, Middleſex, England, occupies, as its name partly implies, a high ſituation. It is about four miles north of London, and its buildings are irregularly diſperſed over a large extent of ground, along the ridge, and down the ſloping declivities of a hill. This place is ſaid to derive its name from a gate-houſe, or gate, that was formerly ſtanding at the top of the hill, and belonged to the biſhops of London, who exacted toll from all perſons with carriages, horſes, cattle, &c. that paſſed through it. Before this toll-bar was raiſed and road formed, the road from London to Barnett and northwards, was through Hornſey-park to Colney-Hatch, &c., but this being very "miry and deep in winter," as Norden ſtates, it was agreed between the biſhop of London and the landholders in this part of the country, that a new road ſhould be formed "through the park, at Highgate Hill," by the former, and that he and his ſucceſſors ſhould be authoriſed to collect toll from all paſſengers. At the time Norden wrote, this toll was farmed for 40*l.* annually; and in 1794 it was rented at 150*l.* a year. The gate-houſe was taken down in 1769, when the road "was opened at the joint expence of the Iſlington and Whetſtone truſt," as expreſſed on a board attached to a tavern built on the ſcite of the old toll-houſe. Tolls are ſtill demanded for cattle, loaded carriages, and horſes for ſale. Near the gate-houſe is the parochial chapel, one aiſle of which was erected in 1565, and the other at a later period. It contains two or three monuments with buſts, &c., and in it ſome perſons of eminence have been interred. Among whom the following names occur: William Platt, eſq., who died in 1637; Lewis Atterbury, LL. D. obiit 1731; ſir Francis Pemberton, died 1697. Connected with the chapel is a free-ſchool houſe, which owes its erection to ſir Roger Cholmeley, knight, chief juſtice of the Queen's Bench in 1562, who alſo bequeathed a legacy to defray the education of poor boys of Highgate, and to ſupport a maſter, &c. The ſchool-houſe occupies the ſcite of an ancient hermitage. Highgate is noted, among the lower claſſes of the community, for a ſilly, burleſque, nugatory oath, which the inhabitants of ſome of the public-houſes occaſionally adminiſter to their viſitors. A pair of large horns is placed on the head of the perſon, and he is required to ſwear "that he will not eat brown bread when he can get white; will not drink ſmall beer when he can get ſtrong; will not kiſs the maid when he can kiſs the miſtreſs," &c. This abſurdity was probably invented by a cunning publican, to attract cuſtomers, and his ſcheme at firſt gave conſiderable publicity to the houſe and village, but is now ſeldom employed. Highgate is a great thoroughfare to the northern parts of England and Scotland. Hence a vaſt number of coaches, waggons, &c. paſs through it daily. The hill, from Holloway to the chapel, is long and ſteep. To avoid this ſteep aſcent different ſchemes have been propoſed at different periods, but hitherto all that has been effected to obviate the evil, or leſſen its force, is a removal of ſome feet of earth from the ſummit of the hill, and placing it at the bottom. In the year 1808 a new and novel ſcheme was propoſed by Mr. Robert Varie, an engineer, to form an arched ſubterraneous tunnel, for a public road, through Highgate-hill, and this plan is now proſecuting with avidity.

Highgate, a townſhip of America, being the north-weſternmoſt except Alburgh, in Vermont, Franklin county, containing 324 inhabitants.

HIGHLAND Creek, a river of America, in Kentucky, which runs into the Ohio, N. lat. 37° 32'. W. long. 88° 22'.

Highland *Point*, a cape on the N. E. coaſt of New Zealand, at the entrance of Lowland bay. S. lat. 37° 48'. W. long. 182° 16'.

Highlands, a mountainous tract of country in America, on the banks of Hudſon's river, in the ſtate of New York, between 40 and 60 miles N. of New York city. The paſſage on the river, through theſe highlands, for the diſtance of about 18 miles, is very grand and romantic. In theſe highlands are ſituated the important fortreſſes of Weſt Point, Fort Montgomery, and Stony Point. Theſe mountains abound with iron ore.

Highlands, a natural diviſion of Scotland, formed by the Grampian mountains, and including the northern and mountainous provinces, and applied to this part of the country in contra-diſtinction to the "Lowlands," which comprehend the ſouthern diſtricts. The appellation of Highlands is more ſtrictly confined to Argyleſhire, the coaſt of Perthſhire, and of Inverneſs, and the entire counties of Roſs, Sutherland, and Caithneſs, extending alſo to the Hebrides or Weſtern iſles. The whole of this diſtrict is wild, rugged, and mountainous, ſeparated by vales, from which the direct rays of the ſun are for ſome months intercepted by the elevated mountain, and into which the rivers flowing from them are precipitated. The three principal rivers, formed by numerous ſtreams and torrents iſſuing from the hills, are the Tay, the Spey, and the Forth. Before the commencement of the laſt century, little or no communication ſubſiſted between the Highlands and Lowlands, as they were unconnected by regular roads and bridges, and the entries from the one to the other, were, for the greater part of the year, impaſſable. In order to facilitate an intercourſe between theſe different parts of the country, general Wade, under a commiſſion from George I., travelled, in 1724, to the moſt difficult and dangerous paſſes of the mountains, and projected the bold undertaking of forming ſpacious roads in theſe rugged diſtricts. In 1726 he began the work, and by means of five hundred ſoldiers, employed under proper officers, in the ſummer ſeaſon, he completed it in 1737. Theſe roads were two hundred and fifty miles in length, and from twenty to twenty-five yards broad, guarded from the injuries of the rains and torrents, to which they were ſubject, by aqueducts and ſide-drains. The huge ſtones raiſed out of the ground by means of engines, are ſet up by the road ſide, to ſerve as guides in deep ſnows; and at each interval of five meaſured miles, pillars are erected, on which the number of miles is inſcribed. The roads enter the mountains at three different parts of the low country; one at Crieff, 24 miles N. of Stirling; another at Dunkeld, 12 miles N. of Perth; and the laſt goes along the ſide of Loch-Lomond, in Dunbartonſhire, by Luſs. Since the period in which Gen. Wade finiſhed his operations, the military roads have been farther extended, and a ready communication has been opened with every part of the country. Before the period to which we have now referred, the Highlands of Scotland were in a ſtate ſomewhat ſimilar to that of England before the Norman conqueſt. The inhabitants, who were a branch of the ancient Celtæ, probably the firſt inhabitants of Britain, and who have ſince been called Caledonians, were divided into tribes, called clans. Thoſe of the inferior order were vaſſals of particular chiefs, to whom they were attached, and on whom they relied for that ſafety which the laws could not afford them. On the other hand, the ſecurity and conſequence of a chieftain depended on the number and fidelity of his ſervants and retainers; who, on account of their relation to him, aſſumed a dignity, and acquired in their manners a degree of politeneſs, to which other uncivilized nations are ſtrangers. The rents of farms which theſe vaſſals occupied were inconſiderable, and were chiefly paid by military ſervice: ſo that the value of a proprietor's land was eſtimated, not by the money it produced, but by the men whom it could ſend into the field; and that the number of dependants might be increaſed, the farms or allotments of land were ſmall, and barely ſufficient for a ſcanty ſubſiſtence to the tenants. As an inconſiderable proportion of the country was cultivated, and as no intercourſe ſubſiſted between the inhabitants and any other nation, little time was employed in agriculture and commerce. The greateſt part of it was conſumed in indolence or amuſement, unleſs when their ſuperior ſummoned them to avenge on ſome neighbouring tribe an inſult or injury. No more grain was raiſed, nor was any more raiment manufactured by any family than that which barely ſufficed itſelf. Villages and hamlets, ſituated in vallies for ſhelter, were rudely conſtructed of turf and ſtone. In ſpring the natives ploughed or dug ſome adjacent patches of ſoil, in which barley or oats were ſown; in ſummer they prepared and collected turf and peat for fuel; in autumn they gathered in their ſcanty crops of grain and hay; and the reſidue of the year was devoted to paſtime or predatory excurſions. In winter evenings, around a common fire, the youth of both ſexes generally aſſembled for the ſong, the tale, and the dance. A taſte for muſic was prevalent among them. Their vocal ſtrains were plaintive and melancholy; their inſtrumental airs were either lively for the dance, or martial for the battle. In the time of Oſſian, of ancient celebrity, the harp was the chief inſtrument of muſic; its ſimplicity ſuited the mildneſs of their manners, and its wild notes were well adapted to the poetical effuſions of the bards. In a later period, when the quarrels of their chieftains embroiled them in a ſtate of almoſt continual warfare, the harp yielded to the bagpipe, an inſtrument of the moſt warlike kind, which ſtill continues to ſupply the moſt favourite muſic. The greater part of the Highland muſic, eſpecially the moſt ancient, as ſuited to the harp, is of the ſoft, tender, and elegiac caſt, chiefly expreſſive of the paſſions of love or grief; many of the latter pieces are ſprightly and cheerful, adapted to the regions of fancy and of feſtivity. Other pieces are of a martial nature, every note of which is expreſſive of rage or fury. They have alſo a mixed ſpecies of muſic, intended to commemorate ſome great battle or conteſt, when the elegiac, the martial, the mournful, and the joyful are united; but of all theſe the favourite of the Highlanders is that ſpecies called "Strathſpey reels," uſed in their dances. Every family of note retained an hiſtorian to narrate its heroic deeds and feats of valour, or a bard, who ſung the praiſes of the chieftain and his clan. Some fragments of their poetry

try have been handed down from remote ages, and recently moulded into heroic poems, of which we have a ſpecimen in the poems of Oſſian. Since the extinction of the order and office of bards, the Gallic poems and tales are in a great meaſure loſt or adulterated. The language of the Highlanders is ſtill the Gaelic (ſee Gaelic) ; and the genius and character of its poetry are well known ; being tender, ſimple, beautiful, and ſublime. Strangers, who have ventured to penetrate into the faſtneſſes of the Highlanders, have been received and treated in the moſt hoſpitable manner ; but, as for themſelves, they ſeldom wandered, except for the purpoſes of devaſtation or plunder. The dreſs of the country was the laſt remains of the Roman habit in Europe, well ſuited to the nature of the country and the neceſſities of war. It conſiſted of a light woollen jacket, or tartan, wove in ſquares of various colours, in which red, green, blue and black are moſt prevalent. The feil-bag, or kilt, is a ſhort petticoat of the ſame ſtuff, reaching to the knees ; and the hoſe, or ſhort ſtockings, are woven in diamonds of red and white, tied under the knee with garters, often beautifully ornamented : the Highlanders have generally a pouch made of the ſkin of a badger, fox, or other animal, hanging before, in which they keep their tobacco and money, and this part of their dreſs is generally adorned with ſilver buttons and taſſels ; their plaid is alſo of tartan, conſiſting of twelve or thirteen yards of cloth, wrapped round them in a graceful manner, faſtened round the middle by a belt, falling to the knees behind, and confined by a broach or ſilver pin to the top of the left ſhoulder : this is often their only cover, both within doors, and when obliged to repoſe in the fields. The truis or trews, which are a ſort of tartan pantaloons, are only worn by the gentry, inſtead of the kilt. Indeed, ſir John Sinclair contends, that the trews were the moſt ancient dreſs of the Highlanders, and that the kilt is of comparatively modern introduction. The Highlanders generally affected to have their dreſs of the colour of the heath on which they repoſed, probably from a principle of ſecurity in time of war, or that they might not be diſcovered while they lay in the heaths, waiting for their game. Their ancient arms were the broadſword and target, Lochaber axes, (now only uſed by the town-guard of Edinburgh,) and a dirk (ſhort dagger), to which, before the act for diſarming the Highlanders, in 1748, the piſtol ſtuck into the girdle had been added. Always armed with a dirk and piſtol, they were ready to reſiſt an aſſault, or revenge a provocation, as ſoon as it was given. This circumſtance contributed to render them polite and guarded in their behaviour to one another. When embodied by their chieftain, they were armed with a broadſword, a dagger, a target, a muſket, and two piſtols. In cloſe engagement, and in broken ranks, they were irreſiſtible. The only foe they dreaded was cavalry. As ſoon as the battle was over, moſt of the troops diſperſed, and returned home to diſpoſe of their plunder, and to provide for their families. Their religion was deeply tinctured with ſuperſtition. They believed in ghoſts and apparitions ; by appearances in the heavens they predicted future events ; they practiſed charms and incantations for the cure of various diſeaſes ; and to ſome individuals they thought the divinity had communicated a portion of his preſcience.

The ſtate of Society in the Highlands has been greatly changed and ameliorated ſince the rebellions in 1715 and 1745. The Roman dreſs and the uſe of arms were prohibited by government ; roads, as we have already obſerved, conſtructed at a vaſt expence, opened an eaſy communication with the low country ; and the courts of barons were ſuppreſſed by the juriſdiction act. The heads of clans have now ceaſed to be petty monarchs ; and the ſervices of their vaſſals are no longer requiſite for their defence or aggrandiſement. Diveſted of their legal authority, they now endeavour to preſerve their influence by wealth. With this view their attention is directed to the improvement of their eſtates. Their ancient mode of living is alſo entirely altered ; and the Highland gentleman, in every reſpect, differs little from a proprietor of the like fortune in the ſouthern country. A ſpirit of induſtry has been excited among the tenants, while, in many places, arts and manufactures are encouraged ; and the lower claſſes are, in conſequence of the eſtabliſhment of ſchools, provided with the means of education.

"The Highlanders (ſee Encycl. Brit. art. *Highlanders*), are of a quick and penetrating genius, ſtrongly tinctured with a curioſity or thirſt of knowledge, which diſpoſes them to learn any thing very readily. They are active and induſtrious, where oppreſſion does not diſcourage them by ſecluding even the hope of thriving. They are remarkably bold and adventurous, which qualifies them for being excellent ſeamen and ſoldiers. They are generally of a middle ſize, rather above it than otherwiſe : their eyes are briſk and lively, their features diſtinctly marked, and their perſons tight and well made. Their countenance is open and ingenuous, and their temper frank and communicative."

HIGHLANDERS, in *Rural Economy*, a term frequently applied to the highland, and ſome other ſorts of Scotch cattle.

HIGHMORE, Joseph, in *Biography*, one among the moſt ſucceſsful portrait-painters in England from the time of ſir Godfrey Kneller (under whom he is ſaid to have ſtudied, and who particularly noticed him, by diſtinguiſhing him as the " Young Lawyer"), till the days of Hudſon, and his incomparable pupil Reynolds. He was the third ſon of Mr. Edward Highmore, a coal-merchant in Thames-ſtreet, and nephew of Mr. Highmore, ſerjeant-painter to king William, with whom Mr. (afterwards ſir John) Thornhill ſerved his apprenticeſhip. He was born in the pariſh of St. James, Garlickhithe, June 13th 1692, and was firſt intended for the law, and articled as clerk to an attorney in 1707 ; but he left it for painting, to which his inclination had always attached him, and was much employed. His leiſure hours had been uniformly devoted to the art of deſigning, and to the ſtudy of geometry, perſpective, architecture, and anatomy ; and he made great proficiency in theſe ſeveral departments of ſcience, though he had no other inſtructors than books. Afterwards, indeed, he had an opportunity of attending the anatomical lectures of Mr. Cheſelden, and he entered himſelf at the Painter's Academy, in Great Queen-ſtreet, where he drew for 10 years. It was in the year 1715, on the expiration of his clerkſhip, that he commenced the practice of painting as a profeſſion, and ſettled in the city. In this year Dr. Brook Taylor publiſhed his " Linear Perſpective," whoſe theory our author adopted, and upon which he grounded his ſubſequent practice ; and it has been allowed that few, if any, of the profeſſion were ſo well acquainted with that excellent, though in ſome reſpects intricate, ſyſtem. As his reputation and buſineſs increaſed, he removed from the city to Lincoln's-Inn-Fields, in March 1723-4, where he had an opportunity of introducing himſelf to the nobility, by engaging with Mr. Pine, the engraver, to make drawings for his prints of the knights of the Bath. In the ſummer of 1732 he viſited the continent ; and at Antwerp he had peculiar pleaſure in contemplating the works of Rubens, his favourite maſter. In 1734 he made a ſimilar excurſion to Paris, where he had the ſatisfaction of being ſhewn, by cardinal de Polignac, his famous group of antique ſtatues, the court of Lycomedes, then juſt brought from Rome. In 1750 he had the misfortune

tune to loſe his excellent wife, daughter and heireſs of Mr. Anthony Hiller, of Effingham, in Surrey, whom he had married in 1716. On the firſt inſtitution of the Academy of Painting, Sculpture, &c. in 1753, he was elected one of the profeſſors, an honour which, on account of his numerous avocations, he was under a neceſſity of declining. His principal works were the portraits of the knights of the Bath, on the revival of that order in 1725. In 1754 he publiſhed "A critical Examination of thoſe two Paintings (by Rubens) on the ceiling of the banqueting-houſe at Whitehall, in which architecture is introduced ſo far as relates to perſpective; together with the diſcuſſion of a queſtion which has been the ſubject of debate among painters, *viz.* "Whether parallel perſpective be at all times juſt?" Another literary work gained him more applauſe, *viz.* "The Practice of Perſpective, on the Principles of Dr. Brook Taylor," &c. written many years before, but not publiſhed till 1763. In 1765 he publiſhed, without his name, "Obſervations on a Pamphlet, entitled Chriſtianity not founded on Argument." He alſo publiſhed, with his initials, J. H. two ſmall volumes of "Eſſays, Moral, Religious, and Miſcellaneous, with a Tranſlation, in Proſe, of Mr. Brown's Latin Poem on the Immortality of the Soul." He alſo communicated to the public, through the medium of the Gentleman's Magazine, for 1769, "A natural and obvious Manner of conſtructing Sun-dials, deduced from the Situation and Motion of the Earth with reſpect to the Sun;" and in that for 1778, his remarks on colouring ſuggeſted, by way of a note on the "Epiſtle to an eminent Painter." Of his numerous portraits, during an extenſive practice of 46 years, ſeveral of which have been engraved, our limits will not allow us to give a minute detail. Some of the moſt capital of his performances in the hiſtorical branch were "Hagar and Iſhmael," a preſent to the Foundling hoſpital; "The good Samaritan;" "The finding of Moſes;" "The Harlowe Family," as deſcribed in Clariſſa; "Clariſſa;" "The Clementina" of Grandiſon; and the "Queen-mother of Edward IV. with her younger Son, &c. in Weſtminſter Abbey." In 1761 he retired from buſineſs, and in 1762 removed to the houſe of the Rev. Mr. Duncombe, who had married his daughter, at Canterbury, where he paſſed the remainder of his life, without ever reviſiting the metropolis. His mind, however, retained its powers of activity, and he was always uſefully as well as agreeably employed. A ſtrong conſtitution, habitual temperance, and conſtant attention to his health in youth, as well as age, prolonged his life, and preſerved his faculties to his 88th year; and he may be ſaid to have fallen aſleep on March 3, 1780. He was interred in the ſouth iſle of Canterbury cathedral, leaving one ſon, Anthony, educated in his own profeſſion, and a daughter, married to Mr. Duncombe. His talents and character will be reſpected by all who have a taſte for the arts and for principles of religious virtue, exemplified by a correſponding practice. One of his grandſons, Anthony Highmore, eſq. is now an eminent ſolicitor in London, and traces the footſteps of his anceſtor by his general conduct.

HIGHMORE, NATHANIEL, a phyſician and anatomiſt, was born at Fordingbridge, in Hampſhire, on the 6th of February 1613. He went to Oxford, where he was elected a ſcholar of Trinity College in 1632, and took his degree of M.D. in 1642. He ſettled at Sherborne, in Dorſetſhire, where he obtained a conſiderable ſhare of reputation in the practice of his profeſſion. He died on the 21ſt of March 1684, at the age of 71, and was buried at Candlepurſe in that county, of which place his father had been rector. Dr. Highmore, though with limited opportunities of diſſection, purſued the ſtudy of anatomy with zeal, and his name has remained attached to ſome diſcoveries not ſtrictly his; as that of the *antrum maxillare*, of which he obtained a view from an extracted tooth, which ſuggeſted the operation of piercing into it from the jaw, practiſed by Cowper. Caſſerius had mentioned the cavity under the name of *antrum genæ*. His principal work is, "Corporis humani Diſquiſitio Anatomica," printed at the Hague in 1651, in folio. The deſcriptions in this work are too brief, and the reaſonings unneceſſarily copious; and the figures chiefly copied from Veſalius. His other writings are, "Exercitationes duæ, quarum prior de paſſione hyſtericâ, altera de affectione hypochondriaca," Oxon. 1660. Theſe diſſertations abound with phyſiological remarks and hypotheſes, ſome of which are ingenious, but were attacked by Dr. Willis. In conſequence of this, Highmore printed, in 1670, "De hyſterica et hypochondriaca paſſione, Reſponſio Epiſtolaris ad Williſium." He likewiſe publiſhed "A Hiſtory of Generation," 8vo. 1651, which has ſome good figures of the embryo in the egg, during the ſtate of incubation. Gen. Biog. Eloy. Dict. Hiſt.

HIGHNESS, a quality, or title of honour, given to princes.

The kings of England and Spain had formerly no other title but that of highneſs; the firſt, till the time of Henry VIII. and the ſecond, till that of Charles V. See KING.

The petty princes of Italy began firſt to be complimented with the title of highneſs in the year 1630. And the duke of Orleans aſſumed the title of royal highneſs, in the year 1631, to diſtinguiſh himſelf from the other princes of France.

The duke of Savoy, afterward king of Sardinia, bore the title of royal highneſs, on account of his pretenſions to the kingdom of Cyprus. It is ſaid that the duke only took the title of royal highneſs, to put himſelf above the duke of Florence, who was called *great duke*; but the great duke has ſince aſſumed the title of royal highneſs, to put himſelf on a level with the duke of Savoy.

The prince of Condé firſt took the title of moſt ſerene highneſs, leaving that of ſimple highneſs to the natural princes.

At preſent, all the ſons of crowned heads are ſtyled royal highneſs, as the electors of Germany are called electoral highneſs.

HIGHWORTH, in *Geography*, a market town and pariſh in a hundred of the ſame name, and county of Wilts, England, is ſituated on a hill, whence its name appears to have been derived. It was formerly called a borough, but at preſent has no other privileges than the right of electing a mayor and aldermen, who poſſeſs ſome nominal powers. The pariſh of Highworth conſiſts of about 2000 acres of land, and compriſes ſeveral chapelries and hamlets. The principal of theſe is Seven-hampton, a chapelry annexed to this vicarage. In this the Warneford family long had a ſeat; and built for themſelves a private oratory, or a monumental chapel, on the ſouth ſide of Highworth church, wherein there are ſome pieces of ancient armour. In the ſame church is a mural tablet to the memory of ſir John Croft, bart. of Dunſtan Park, Berkſhire, who died in 1797. Againſt one of the pillars is a table, containing a long liſt of charitable donations to the poor. The petty ſeſſions, for the diviſion of Highworth, are held at this town, and a fixed pillory is preſerved in the market place. Here are a ſmall weekly market on Wedneſdays, and three annual fairs. About three miles W. of the town, in the tything of Broad-Blunſden, is an ancient encampment, on an eminence called Caſtle Hill, near which a Roman road from Spinæ to Corinium, paſſed. Two miles eaſtward of Highworth is Coleſhill-houſe, Hill-houſe, the ſeat of lord Folkſtone. The houſe was built from the deſigns of Inigo Jones. Highworth contained 254 houſes in the year 1801, and 1493 inhabitants. Britton's Beauties of Wiltſhire.

HIGLER is a name frequently mentioned in our ſtatutes for a perſon who carries from door to door, and ſells by retail ſmall articles of proviſions, &c. They are laid under various reſtraints by the ſtatute laws. See Hawkers.

HIGUERA, in *Geography*, a town of Spain, in Eſtremadura; 12 miles north of Xeres de los Caballeros.—Alſo, a town of Mexico, in the province of Cinaloa; 28 miles E. of Cinaloa.

Higuera, *Cape*, a cape of Spain, on the coaſt of Biſcay. N. lat. 43° 22'. W. long. 1° 55'.

HIGUEY, or Yguey, *Alta Grecia*, a city in the S.E. part of the Spaniſh diviſion of St. Domingo, the moſt eaſterly of all the ſettlements in the iſland, celebrated formerly for its fertility, and for the quantity of ſugar which it produced. It has now only about 500 inhabitants, and is diſtant about 40 leagues E. of St. Domingo.

HIHA, a town of Abyſſinia, 40 miles E. of Axum.

HIJAR, or Ixar, a town of Spain, in Aragon; 25 miles S.E. of Saragoſſa.

HIIS Testibus, *q. d. theſe witneſſes*, in *Law*, a phraſe anciently added in the end of a deed, written in the ſame hand with the deed; upon which the witneſſes were called, the deed read, and then their names entered. See Witness.

The clauſe of *hiis teſtibus*, in ſubjects deeds, continued till, and in, the reign of Henry VIII. but it is now omitted. Coke on Littleton.

HIKE, in *Rural Economy*, a term implying to ſtrike with the horn, in the manner cattle often do.

HILARIA, in *Antiquity*, feaſts celebrated every year, by the Romans, on the eighth of the calends of April, or the 25th of March, in honour of Cybele, the mother of the gods: as is obſerved by Macrobius, lib. i. cap. 10. and Lampridius, in his life of Alexander Severus.

The hilaria were ſolemnized with great pomp and rejoicing. Every perſon dreſſed himſelf as he pleaſed, and took the marks or badges of whatever dignity or quality he had a fancy for. The ſtatue of the goddeſs was carried in proceſſion through the ſtreets of the city, accompanied by multitudes in the moſt ſplendid attire. The day before the feſtival was ſpent in tears and mourning. Cybele repreſented the earth, which, at this time of the year, begins to feel the kindly warmth of the ſpring; ſo that this ſudden tranſition from ſorrow to joy was an emblem of the viciſſitude of the ſeaſons, which ſucceeded one another.

The Romans took this feaſt originally from the Greeks, who called it αναβασιν, *q. d. aſcenſus*; the eve of that day they ſpent in tears and lamentations, and thence denominated it καταβασις, *deſcenſus*.

Afterwards the Greeks took the name ἱλαρια, from the Romans; as appears from Photius, in his extract of the life of the philoſopher Iſidore.

Caſaubon maintains, that beſide this particular ſignification, the word hilaria was alſo a general name for any joyful or feſtival day, whether public, or private and domeſtic. But Salmaſius does not allow of this.

Triſtan, tom. i. p. 482, diſtinguiſhes between hilaria and hilariæ. The former, according to him, were public rejoicings; and the latter, prayers made in conſequence thereof; or even of any private feaſt or rejoicing, as a marriage, &c. The public laſted ſeveral days, during which all mourning and funeral ceremonies were ſuſpended.

HILARION, in *Biography*, the founder of the monaſtic life in Paleſtine, was born at Gaza, in 291, of a Pagan family, but quitted the errors of his fathers and embraced Chriſtianity. He diſtributed all his property among the poor, and withdrew into a deſert, where he paſſed his time in ſolitude and devotion, and acquired a high character for piety and devotion. The number of his diſciples ſoon became very numerous, whom he diſtributed into different eſtabliſhments throughout Paleſtine and Syria, over which he exerciſed a moſt vigilant ſuperintendance. He died in the year 371, at the iſland of Cyprus.

HILARIUSE, Joseph, an eminent antiquary and medalliſt, was born at Enzesfield, in Lower Auſtria, in 1737. He was educated among the Jeſuits, and afterwards became an eminent teacher of grammar and rhetoric at Vienna, of which college he was appointed præfectus rei nummariæ. In the year 1770 he renounced the vows of his order, and in a ſhort time after was appointed profeſſor and director of the Imperial cabinet of ancient coins. He was likewiſe dean of philoſophy and the fine arts. He died in 1798, leaving behind him a high character for extenſive knowledge, irreproachable morals, and great wit.

HILARODI, Ἱλαρῳδοι, compounded of ἱλαρος, *joyful*, and ᾠδη, *ſong*, in the *Ancient Muſic* and *Poetry*, a ſort of poets among the Greeks, who went about ſinging little merry diverting poems or ſongs; though ſomewhat graver than the Ionic pieces

The hilarodi appeared dreſſed in white, and were crowned with gold. At firſt they wore ſhoes; but afterwards they aſſumed the crepida, which was only a ſoal, tied over the foot with ſtraps.

They did not ſing alone, but had always a little boy or girl to attend them, playing on ſome inſtrument.

From the ſtreets they were at length introduced into the tragedy, as the magodi were into comedy.

The hilarodi were afterwards called Simodi, from a poet named Simus, who excelled in this kind of poetry.

HILARODIA, a poem, or compoſition in verſe, made or ſung by a kind of rhapſodiſts, called hilarodi.

HILARO-TRAGŒDIA, a dramatic performance, partly tragic or ſerious, and partly comic or merry.

Scaliger holds, the hilaro-tragœdia and hilarodia to be one and the ſame thing. Others rather take the hilaro-tragœdia to have been pretty nearly what we call a tragi-comedy. Others, again, will have it to have been a pure tragedy, only terminating with a happy cataſtrophe, which brings the hero out of a wretched into a fortunate ſtate. But the firſt opinion ſeems the moſt probable, and the beſt warranted.

Suidas mentions one Rhinthon, a comic poet of Tarentum, as the inventor of this kind of poem: whence it was alſo called *Rhinthonica fabula*.

HILARY, in *Biography*, was biſhop of Poictiers in Aquitania, and flouriſhed about the year 354. He is placed by Jerom among his illuſtrious men, from whom we learn that, after his converſion to Chriſtianity from the Pagan religion, he became a zealous champion for what was then deemed the orthodox faith againſt the Arians, labouring to confute them by his writings, and condemning their opinions by the councils which he cauſed to be aſſembled at Poictiers. His twelve books on the Trinity, his treatiſe concerning ſynods addreſſed to the biſhop of the Gauls, and his Commentaries upon the Pſalms, the Goſpel of St. Matthew, the Book of Job, and the Canticles, are mentioned by Jerom as his principal works. Of theſe the laſt and beſt edition is that of the Benedictines at Paris, in 1693. Hilary died at Poictiers, in the reign of Valentinian and Valens, about the year 366. In his Prologue to the Commentaries on the Pſalms, Hilary gives a catalogue of the books of the Old Teſtament;

he appears to have received the Epiſtle to the Hebrews, though it was not univerſally received by the Latin Chriſtians, and he often quotes the book of the Revelation, and aſcribes it to John the apoſtle.

HILARY, deacon of Rome, was born in Sardinia, and appointed to his office about the year 354. He is mentioned by Jerom in his account of eccleſiaſtical writers, who repreſents him as a zealous Homoüſian, and afterwards a rigid Luciferian; and he pleaſantly calls him another Deucalion, as if he would bring again an univerſal deluge on the world, becauſe he was for rebaptiſing Arians, and other heretics, when they came over to the church. Differing from other Chriſtians in this particular, he ſeparated from the church, and wrote treatiſes in favour of his opinion. Cave aſcribes to Hilary the "Commentary upon Thirteen of St. Paul's Epiſtles," uſually joined with St. Ambroſe's works, which he ſuppoſes to have been written before the year 384; and this learned writer conſiders him alſo as the author of "Quæſtiones in Vetus et Novum Teſtamentum," written about 370, and uſually joined with St. Auguſtine's works. Several other writers concur with Cave in aſcribing the firſt work to Hilary, but differ with regard to the latter; and indeed both works are much interpolated. Hilary, conſidered as the author of the Commentaries, &c. quotes moſt books of the Old and New Teſtament. Lardner's Works, vol. iv.

HILARY, a ſaint in the Roman calendar, born at Arles in 401, of noble and very opulent parents, was diſtinguiſhed while very young by his proficiency in knowledge and the brilliancy of his talents. Having been perſuaded by his relation Honoratus, to devote himſelf to the religious life, he ſold his patrimonial eſtate, diſtributed the money ariſing therefrom among the poor, and entered into a monaſtery, where he ſubjected himſelf to the auſterities of the cloiſter, and applied with diligence to theological ſtudies. He was promoted to the ſee of Arles in the year 429, which forced him from his cloiſter into the more active ſcenes of life. Having entered upon the epiſcopal duties of his ſee, he diſcharged them with uncommon zeal and aſſiduity, ſetting before his flock an illuſtrious example of the virtues which he recommended to their practice. He was an eloquent and impreſſive preacher, and freely reproved the vices of the great, without being moved by a dread of their diſpleaſure. He preſided in a council at Orleans in 441, and died in 449, at the early age of 49. His works are (1) "Homilies;" (2) "The Life of St. Honoratus;" (3) "An heroical Poem on the early part of the Book of Geneſis;" and "A ſhort Letter to Eucherius biſhop of Lyons," which may be found in the ſeventh volume of the Biblioth. Patrum. Moreri.

HILARY, or **HILARIUS**, pope, was a native of Sardinia, and while he was only a deacon in the church, he was ſent, with the character of pope Leo's legate, à latere, to aſſiſt at the general council ſummoned to meet at Epheſus, in the year 449, for the purpoſe of deciding on the queſtions at iſſue between Eutyches and Flavianus, patriarch of Conſtantinople. In that council he embraced the intereſts of Flavianus, and proteſted with great firmneſs and intrepidity againſt the ſentence of his depoſition. His conduct on this occaſion led him into difficulties, and withdrawing unexpectedly from Epheſus he travelled by night, and in roads not uſually frequented, till he thought he had perfectly eſcaped the power of Dioſcorus, who had preſided at the council. After this he was raiſed to the archdeaconry of the Roman church, and from this ſtation he was elevated, in the year 461, to the papal dignity. No ſooner was he ordained, than he devoted his principal care to the extenſion of the power and authority of the Roman ſee. In the year 462 he held a council at Rome, at which he enacted ſuch decreees as ſuited his own views, having met with no oppoſition from the biſhops who were aſſembled at this time. So ſubmiſſive were the prelates to the edicts of Hilarius, that he had an opportunity of extending his own authority every day, and making them entirely dependent upon him, by favouring the pretenſions ſometimes of one and ſometimes of another. In the year 465, an opportunity offered of attempting to extend the papal authority over the churches of Spain, and he ſent a ſub-deacon into that country to ſee that his pleaſure ſhould be carried into effect. In their letters to the pope, the Spaniſh prelates had been induced to expreſs the greateſt reſpect for the apoſtolic ſee, and to acknowledge the biſhop of Rome for the ſucceſſor of St. Peter, "whoſe primacy ought to be loved and feared by all." Hilary, in the year 467, violently oppoſed a deſign of the new emperor Anthemius, to grant leave to the ſeveral ſects of Chriſtians to aſſemble publicly by themſelves, to own openly the doctrines which they held, and to ſerve God in the manner which they believed moſt agreeable to him. This noble deſign was ſuggeſted to the emperor by one of his favourites, who was friendly to the rights of conſcience; but the pope, to whoſe authority ſuch a meaſure muſt ultimately prove fatal, obliged the emperor to relinquiſh his deſign, and to take an oath that he would ſuffer no ſchiſmatical aſſemblies to be held at Rome. Hilary died in the courſe of the ſame year, having preſided at the head of the church nearly ſix years. Twelve of his letters may be found in the fourth volume of the "Collect. Concil." Moreri.

HILARY, or *Helier*, *St.* in *Geography*, the principal town in the iſland of Jerſey, conſiſts of ſeveral ſtreets. It is protected from the north winds by high grounds, and is open to the ſea on the ſouth-weſt. Between the town and the hills is a tract of fine meadows, watered by a rivulet which deſcends from the hills, and paſſing in different channels through the town, is a pleaſant and beneficial appendage to the place. Near the centre of the town is a large quadrangular area, ſurrounded by reſpectable houſes, among which is the court-houſe, or ſeat of juſtice, called La Cohue Royale. St. Hilary is moſtly occupied by merchants, ſhopkeepers, artificers, and dealers in liquor. For the accommodation of perſons attending the market, which is kept every Saturday, here are different buildings and places adapted to their reſpective purſuits. For the dealers in corn there is a building, ſupported by pillars, and ſhambles for the butchers. The parochial church is large and commodious, and the ſervice is alternately performed in French and Engliſh. Among the monuments it contains, is one to the memory of major Pearſon, who was killed in defending the town in Jan. 6, 1781, when a party of French, under baron de Rullicourt, had invaded the iſland. The garriſon and the lieutenant-governor had capitulated, but the major, with a few ſoldiers, rallied, and, though the former loſt his life, he was the cauſe of ſaving the iſland; for the French commander was killed and his ſoldiers taken priſoners. The harbour is protected by a ſtrong caſtle or fort, the reſidence of the governor, or lieutenant-governor of the iſland. It occupies the whole of a ſmall iſland, at the diſtance of about half a mile from the town, and is acceſſible by a cauſeway at low-water. On the top of a high rocky hill, near the town, was diſcovered, in the year 1785, a maſs of ſtones ranged in a circular form, ſome perpendicular, and others lying horizontally on the former. It was called a Druidical temple, and was completely covered with earth at the time of diſcovery. General Conway, then governor, had the ſtones removed to Park Place, in Berkſhire, where they were again erected and diſpoſed in their original form. The circle is 66 feet in circumference, and conſiſts of forty-five ſtones, ſome of which are ſeven feet in height. (See Jersey.) Gough's Camden, and Fall's Account of Jerſey.

Hilary *Term*, in *Law*. See Term.

HILAUI, or Uabe, in *Geography*, a town of Peru, in the dioceſe of La Paz; 25 S.W. of Chicuito.

HILAY, a ſmall iſland in the Pacific ocean, near the coaſt of Peru; S. lat. 16° 50'.

HILBERG, a town of Norway, in the dioceſe of Drontheim; 44 miles W. of Romſdal.

HILBURGHAUSEN, a town of Germany, and capital of a principality, belonging to a branch of the houſe of Saxony, called Saxe-Hilburghauſen, ſeparated from Coburg in the year 1672; the town is ſeated on the Werra, and is the uſual reſidence of the duke; 32 miles E. of Erfurt. N. lat. 50° 19'. E. long. 10° 55'.

HILCONAUR, a town of Hindooſtan, in Bednore; 10 miles N.N.E. of Simogu.

HILDANUS, in *Biography*. See William Fabricius.

HILDEGARDE, a female ſaint in the Roman calendar, was born in the county of Spanheim, in the Palatinate, in the year 1098. She was at an early period devoted to a religious life, and in proceſs of time was choſen abbeſs of St. Rupert's Mount, near Bingen, on the Rhine. Here ſhe acquired a character for a high degree of ſanctity, and aſſumed the pretenſions and powers of a propheteſs, divinely inſtructed, in dreams and viſions, to announce to mankind the will of God. Her claims were well adapted to the dark and ſuperſtitious age in which ſhe lived, and occaſioned an immenſe reſort to her of credulous perſons of all ranks, who conſulted her as an oracle, and reſpected her deciſions as the commands of the moſt high God. Several of the popes, to further their own objects, pretended to credit her miraculous powers, and were among the number of her correſpondents, as were the archbiſhops of Mentz, Cologne, Treves, and other prelates on the continent. To all their letters ſhe returned anſwers in a myſtical and prophetical ſtyle. She died in the year 1180, leaving behind her many works which were at the time in high eſtimation; of theſe a part of the following are now to be met with in the Biblioth. Patrum: "Scivias, ſeu Viſionum ſive Revelationum, lib. iii. 1513, fol.;" "Vita S. Roberti Confeſſoris Bingiorum Ducis;" "Epiſtolæ, xxxviii.;" "Quæſtiones Variæ in Scrip. Sac.;" and "Expoſitio Regulæ S. Benedicti." Moreri.

HILDESHEIM, in *Geography*, lately an eccleſiaſtical ſtate of Germany and a princely biſhopric, bounded on the N. by the duchy of Luneburg, on the E. by the duchy of Wolfenbuttle, and the principality of Halberſtadt, on the S. by the principality of Calenberg, and on the W. by Calenberg, and extending from E. to W. about 40 miles, and 32 from N. to S. The ſoil of the greateſt part of this ſtate is fit for tillage, and produces corn, flax, hops, and legumes in abundance; but its breed of cattle, horſes, ſheep, and ſwine is merely ſufficient for the conſumption of the inhabitants. The ſouth part is hilly, and is for the moſt part covered with oak, beech, aſh, and birch, and where it is deſtitute of wood, it has mines of iron. This ſtate contains 12 towns, the chief of which are Hildeſheim and Paina, and 248 villages: its principal rivers are the Leine, Innerſee, and Ocker. The biſhopric was founded by Charlemagne in 822. The inhabitants are partly Lutherans and partly Roman Catholics. In 1803 this biſhopric was ſeculariſed, and given among the indemnities to the king of Pruſſia, but in 1807, after the peace of Tilſit, it was transferred to the new kingdom of Weſtphalia.

Hildesheim, formerly one of the Hanſe-towns, a city of Weſtphalia, to whoſe ſovereign it was ſurrendered in 1807, ſituated near the Innerſee, is an old-faſhioned, large, irregular town, divided into the New and Old towns, which were united in 1583. The magiſtrate, and moſt of the inhabitants, are Lutherans; the reſt are Roman Catholics, who are in poſſeſſion of the cathedral; but the Proteſtants have eight churches; 26 miles W.S.W. of Brunſwick. N. lat. 52° 12'. E. long. 10°.

HILDESLEY, Mark, in *Biography*, an Engliſh prelate, was born at Markſton, in Kent, in 1698, and educated at the Charter Houſe, from whence he was ſent to Cambridge, where he was choſen fellow, in the year 1723. Being admitted into holy orders, he was appointed one of the preachers at Whitehall, and was afterwards made chaplain to lords Bolingbroke and Cobham. In 1731 he obtained the living of Hitchin in Herefordſhire, and ſhortly after he was inducted to the living of Holwell in Bedfordſhire, where he diſtinguiſhed himſelf as a diligent pariſh prieſt. On the death of Dr. Wilſon, biſhop of Sodor and Man, he was appointed his ſucceſſor, but before his conſecration he was created doctor of divinity by archbiſhop Herring. During the period of ſeventeen years, in which Dr. Hildeſley preſided over the dioceſe of Man, he took every method in his power to promote the intereſts of the people over whom he was placed. He procured an entire tranſlation of the Old and New Teſtament to be made into the Manks language. This work had been begun by his predeceſſor biſhop Wilſon, who, at his own expence, had printed the goſpel of St. Matthew, and had prepared for the preſs the other evangeliſts, and the Acts of the Apoſtles. Dr. Hildeſley was enabled to indulge his own liberal ſpirit in this deſign, as well by the aſſiſtance which he received from many perſons of rank and eminence, as by an income which he derived from the maſterſhip of Sherburn hoſpital, preſented to him by the biſhop of Durham, and which he held with the biſhopric till his death. The worthy prelate had this work ſo much at heart, that he frequently ſaid, with the feelings of an humble but anxious mind, "he only wiſhed to ſee it finiſhed, and that then he ſhould be happy, die when he would." On the 28th of November 1772, he received the laſt part of the tranſlation, when in the preſence of an affectionate and congratulating family, he ſung with pious emphaſis, "Nunc Domine Dimittis!" On the next day he officiated in his own chapel, and preached with unuſual energy on the uncertainty of human life, and on the following day he was attacked by a ſtroke of apoplexy, which ſoon deprived him of his intellectual powers, and proved fatal to him in a very few days, when he was in the ſeventy-fourth year of his age. Gen. Biog.

HILELA, or Halef, in *Geography*, a town of Africa, in the country of Sugulmeſſa.

HILL, Joseph, in *Biography*, was born at Bromley, in Yorkſhire, in 1625, and received his college education at St. John's, Cambridge, after which he became fellow of Magdalen college, from whence, on account of his nonconformity, he was ejected in the year 1662. He died paſtor of a congregation at Rotterdam in 1707. He publiſhed an enlarged edition of Schrevelius's Greek Lexicon, and was author of "Diſſertations on the Antiquity of Temples and Churches."

Hill, Aaron, an Engliſh poet, was born in London in 1685, and was left almoſt wholly unprovided before he had attained the age of fourteen, by the death of his father. He had naturally an adventurous ſpirit, and at the age of fifteen took a voyage to Conſtantinople, where his relation, lord Paget, was ambaſſador from the Engliſh nation. He was received with ſurpriſe, but treated with great kindneſs, and a tutor provided for him, under whoſe care he travelled through Paleſtine, Egypt, and various parts of the Eaſt. In 1703 he returned to his own country with lord Paget, who would have provided for him, but the death of his lordſhip deprived him of all hopes from that ſource. Some time afterwards he travelled for three years with ſir W. Wentworth on the tour of Europe. In 1709 he appeared before the public as an author, by "A Hiſtory of the Ottoman Empire," partly from materials which he collected in that country: in the ſame year he publiſhed a poem in favour of the earl of Peterborough, which introduced him to the favour of that nobleman, and to the notice of the heads of the Tory party. He now became manager of the Drury Lane theatre, for which he wrote his Elfrid, or the Fair Inconſtant. Upon ſome difference with the duke of Kent, who was lord chamberlain, Hill threw up his theatrical management, which he had conducted entirely to the ſatisfaction of the public. He was a man of warm feelings, and a good deal given to projects. He obtained a patent for extracting oil out of beech maſt, and a company of ſubſcribers was formed for the purpoſe of carrying the undertaking into effect. The trial was fairly made, but experience ſhewed the folly of the ſcheme, and after three years it was abandoned. He became maſter of the Opera houſe, and wrote for it the opera of Rinaldo, the firſt which Handel compoſed in England. About the year 1718, he publiſhed a poem, entitled the Northern Star, or a panegyric on Peter the Great, for which the empreſs Catherine ſent him a gold medal. He died in February 1750, in his ſixty-eighth year, and was interred in the cloiſters of Weſtminſter Abbey. His character has been given by one of his biographers in a few words; "he was a great ſchemer as well as a poet; but as in the former character he never acquired riches, ſo in the latter he never roſe above mediocrity." His works were publiſhed in four volumes 8vo. after his death. He was a man of active and extenſive benevolence: he was kind and affectionate in all the relations of ſociety, and few men have been more beloved. Of his various plays, two of them, *viz.* Zara and Merope, are ſtill occaſionally brought forward with applauſe; but a dramatic writer and poet cannot claim a high rank, whoſe beſt pieces are tranſlations.

HILL, in *Geology*, a leſs eminence or elevation on the ſurface of the earth, with reſpect to height and extent, than a *mountain*; which ſee.

To find the height of a hill, ſee the latter part of the article LEVELLING.

On the *ſtructure* of hills it may be proper to obſerve, that the far greater part of the hills on the ſurface of the earth are occaſioned by the *Excavation* of an adjacent valley, (ſee that article,) and ſuch hills have the edges of the ſtrata compoſing them only viſible towards or in the ſlopes of ſuch vallies; another claſs of hills, and which frequently form ridges of conſiderable length, is occaſioned by the out-crop, baſſet, or *Ending* of rocks and other thick and hard ſtrata, (ſee that article), and ſuch hills only exhibit the edges of their ſtrata on one ſide, which is more commonly their W. or N.W. ſide than any other, and which Mr. A. Aikin calls their eſcarpement, facing of which there uſually is a plane or comparatively flat country: to the hills of this claſs are to be referred the edges of denudated tracts, like thoſe of chalk which ſurround the wealds of Suſſex, Kent, and Surrey, the grit-ſtone which ſurrounds the valley of Aſhover, or the central lime-hill of brick in Debyſhire, the red marle which ſurrounds the Aſhby-de-la-Zouch coal-field in Derbyſhire and Leiceſterſhire, the firſt grit rock which, like a lengthened horſe-ſhoe, ſurrounds three ſides of the great mineral lime-ſtone tract of Derbyſhire and Staffordſhire, &c.: it being extremely rare, that faults or vertical derangements, or what M. De Luc calls angular motions of the ſtrata, has occaſioned hills or cliffs. A third claſs of hills has recently been denominated *Hummocks* by Dr. W. Richardſon, (ſee that article,) and theſe are compoſed of piles of ſtrata left in the area of a ſurrounding denudation, or abruption, juſt as labourers leave dead-men or buoys in removing tracts of ground, in order for their maſters to ſee and thereby meaſure the quantity of earth which has been removed: theſe curious hills are not peculiar to the iſolated knowles of low tracts, but after the hummocks of ſtrata which have been removed for miles all around, form the higheſt points in the diſtrict. In the liſt of hills with the top ſtratum of each, which Mr. Farey has given in his Report on Derbyſhire, (ſee alſo Phil. Mag. vol. xxxvii. p. 161.) a great number of hummocks are noticed: in this claſs of hills the top ſtratum, at leaſt, has its edges on all ſides expoſed, as otherwiſe it would belong to one of the former claſſes, though frequently more edges of ſtrata are to be ſeen on one ſide than on the other, particularly if the ſtrata in the hummock have a conſiderable dip or inclination, and ſuch are called by Mr. Jameſon ſhield-formed ſtrata. (Geognoſy, vol. iii. p. 64.) Gravel or other alluvial matters are often heaped upon hills, ſo as to form caps or hummocks thereon; and ſometimes, though very rarely, hills may be found compoſed wholly of heaps or hummocks of gravel or alluvia. It remains to mention only one other claſs of hills, which are compoſed of unſtratified maſſes, like thoſe of Charnwood foreſt in Leiceſterſhire, and numerous other anomalous maſſes or nodules in the red-earth or marle of England, the limeſtone-ſhale and others of the Britiſh ſeries of ſtrata, and of other parts of the world. On the height of Britiſh hills, we muſt refer to the ample liſts given in Mr. Jameſon's Geognoſy, vol. iii. pages 313 to 320; and for the ſtrata which are found on the top of each of about 700 hills in Derbyſhire and the adjoining counties, to Farey's Derbyſhire Report, vol. i. p. 16.

HILL, in *Geography*, a town of America, in Virginia, on the Rappahannock; 17 miles N.N.W. of Urbanna.

HILL'S *Bay*, a bay in Cheſapeak bay. N. lat. 37° 32'. W. long. 76° 20'.

HILL *Creek*, a river of America, which runs into the Ohio, N. lat. 38° 57'. W. long. 84° 45'.—Alſo, a river of Maryland, which runs into the Potowmack, N. lat. 39° 40'. W. long. 78° 23'.

HILL *and Trough*, in *Mining*, are uſed to denote ſtrata which alternately riſe and fall in parallel lines, ſimilar to the ſurface of ridges and furrows in ſome ploughed fields, hence called rigg and fur, or ridge and furrow, by the colliers, where the floor of their coals aſſume this ſhape, which ſometimes, though rarely, is the caſe. The floor of the fuller's-earth mine, at Hogſtyend, in Wavendon, Bucks, near Woburn, lies in ridge and furrow. The cauſe of theſe and other deviations from planes in the ſtrata, undiſturbed by faults, is deſerving of great attention from geological obſervers.

HILLARY, in *Geography*, a town of Sweden, in the province of Smaland; 42 miles S.W. of Wexio.

HILLEBECK, a town of Norway, in the dioceſe of Aggerhuus; 13 miles S.W. of Chriſtiania.

HILLEBRUN, a town of Sweden, in the province of Geſtricia; eight miles N. of Geffle.

HILLEGURRY, a town of Hindooſtan, in Bednore; 40 miles S.E. of Simogu.

HILLEL, called *Pollio* by Joſephus, in *Biography*, was one of the moſt eminent men that ever exiſted among the Jewiſh doctors, for birth, learning, authority, and poſterity. As to his birth, he was by his mother of the ſeed of David;

with regard to his learning in the Jewiſh law and traditions, the Jewiſh writers, by an unanimous ſuffrage, aſſign him the firſt rank among all the ancient doctors of their nation: as to authority, he occupied the higheſt ſtation of honour among his people during a ſucceſſion of 40 years: for ſo long he filled the chair of preſident of the Sanhedrim at Jeruſalem, with ſingular reputation and honour, rivalling in wiſdom and juſtice his remote predeceſſor Simon the Juſt: and with reſpect to his poſterity, he was ſucceeded in his high office, as well as in his learning and general celebrity, by his lineal deſcendants to the tenth generation. His immediate ſucceſſor was his ſon Simeon, who is ſuppoſed to have been the ſame who took Chriſt in his arms, on his being firſt preſented in the temple, and ſung over him "Nunc dimittis," (Luke, ii.) After Simeon ſucceeded Gamaliel his ſon, who preſided in the Sanhedrim, when Peter and the apoſtles were called before that council (Acts, v. 34.), and was the ſame at whoſe feet Paul was bred up in the ſect and learning of the Phariſees (Acts, xxii. 3.) He was ſucceeded by his ſon Simeon, who periſhed in the deſtruction of Jeruſalem. At a further diſtance in this line of deſcent was R. Judah Hakkadoſh, who is ſaid to have compoſed the Miſhna, and whoſe name on that account has been held in high veneration among the Jewiſh people. In the progreſſion of this deſcent was Hillel the ſecond, who was the compiler of the preſent calendar of the Jews. Hillel, as we have ſaid, was deſcended on the ſide of his mother from the family of David, but by his father he was of the tribe of Benjamin. He was born in Babylon, and at the age of 40 years he came to Jeruſalem, where he devoted himſelf to the ſtudy of the law, and attained to ſuch eminence, that after 40 years he became preſident of the Sanhedrim, being then 80 years old, and continued in that office for 40 years, ſo that according to this account he lived 120 years. He was the founder of a famous ſchool at Jeruſalem, in which he educated above a thouſand ſcholars in the knowledge of the law. Among his diſciples, Shammai was the moſt celebrated, and came neareſt to his maſter in learning of all the Miſhnical doctors: and accordingly he was appointed vice-preſident of the Sanhedrim. When Herod took poſſeſſion of Jeruſalem, in the firſt year of his reign, (A.D. 27.) he put to death all the counſellors of the great Sanhedrim, except Pollio and Sameas, *i. e.* Hillel and Shammai. When the latter became vice-preſident of the former, he did not always concur in opinion with his maſter. There were many points in which they differed; and this difference produced diviſions and quarrels between their ſcholars, ſo that two parties ſubſiſted among the Phariſees of that period; and the contention proceeded ſo far, that ſeveral were ſlain on both ſides. At length, however, the ſchool of Hillel prevailed againſt that of Shammai; the determination, as it is ſaid, having been given for the former by a "Bath Kol," that is, by a voice pretended to have come from heaven, and by this fiction all diſturbances among them were appeaſed. Hillel was of a mild and peaceable temper, but Shammai was of an angry and violent ſpirit; and hence proceeded moſt of the diſputes and conflicts that occurred between the ſchools of theſe two great doctors, of which Shammai being at length weary, conſented to terminate them by the fiction we have now mentioned. Prid. Conn. vol. iv.

HILLER, Matthew, a learned German divine of the Lutheran perſuaſion, was born at Stuttgard in the year 1646. He finiſhed his ſtudies at Tubingen, where he took the degree of M. A. in 1669. He obtained ſome church preferment, and was profeſſor of logic and metaphyſics at Tubingen, and in 1692 he was appointed to the Hebrew profeſſorſhip. After this he was created profeſſor in ordinary of the Greek and oriental languages. He died in 1725, at the age of 79 years. He was author of "Sciagraphia Grammaticæ Hebrææ," and various other works.

Hiller, an ingenious and popular compoſer of comic operas at Leipſic, in the German language, the airs in which were in general favour among the lovers of ſimplicity and unlearned muſic, 30 years ago.

This worthy profeſſor is a candid critic and biographer, and has been the careful editor of innumerable curious ancient and modern muſical productions.

HILLEROD, in *Geography*, a town of Denmark, in the iſland of Zealand; burnt down in 1733, and rebuilt in the following year; 14 miles N.N.W. of Copenhagen.

HILLIA, in *Botany*, is a genus named by Jacquin, in honour of the celebrated ſir John Hill, M. D. the author of various books on the ſubject of natural hiſtory.—Jacq. Amer. 96. t. 66. Linn. Gen. 175. Schreb. 233. Willd. Sp. Pl. v. 2. 239. Swartz. Obſ. Bot. 134. Mart. Mill. Dict. v. 2. Juſſ. 202. Lamarck. Illuſtr. t. 257.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of ſix oblong, acute, erect leaves. *Cor.* of one petal; tube cylindrical, ſix-furrowed, very long; limb in ſix oblong, flat, deep ſegments. *Stam.* Filaments ſix, very ſhort; anthers oblong, erect, within the throat of the corolla. *Piſt.* Germen inferior, oblong, imperfectly hexagonal; ſtyle thread-ſhaped, the length of the tube; ſtigma capitate. *Peric.* Capſule oblong, compreſſed, of two cells. *Seeds* numerous, very ſmall, pappoſe, affixed to the linear receptacle.

Eſſ. Ch. Calyx ſuperior, of ſix leaves. Corolla ſix-cleft, very long. Berry inferior, with two cells and many ſeeds.

Obſ. Six little leaves ſtand under the germen, (within the two larger bracteas,) which Swartz conſiders as an inferior calyx, but this appears to us ſo paradoxical that we prefer calling them bracteas.

1. *H. longiflora.* Swartz. Prod. 58. Curt. Bot. Mag. t. 721. Andr. Bot. Repoſ. t. 145. (H. paraſitica; Linn. Sp. Pl. 1662.)—"Corolla of ſix lanceolate, revolute ſegments. Leaves ovate, acute." A native of moiſt ſhrubby places on the mountains of Jamaica, flowering in the ſummer. The plant is not ſtrictly paraſitical, though its roots creep amongſt the moſſy trunks and branches of old trees. Indeed the name *paraſitica* has been ſuppoſed to have been beſtowed on this plant in alluſion to the literary character of the author, after whom the genus is named. It is a *ſhrub* about a fathom high, branching and ſmooth, with a ſhining, cinereous *bark*. *Leaves* oppoſite, ſpreading, entire, ſcarcely nervoſe, without veins; ſtanding on round, ſmooth, footſtalks. *Flowers* terminal, ſeſſile, ſolitary, very long, white, and extremely fragrant; outer bracteas two, very large, tube of the corolla three or four inches long; anthers white. Stigma bifid, dark green.

2. *H. tetrandra.* Swartz. Prod. 58. Ind. Occ. v. 1. 630. —"Corolla of four ovate ſegments. Stamens four. Leaves obovate." Habitat the ſame as that of the laſt ſpecies. It flowers in Auguſt.—A *ſhrub*, three or four feet high. *Roots* creeping, and throwing out long fibres. *Stem* looſely branched, ſmooth. *Leaves* oppoſite, wedge-ſhaped at the baſe, ſomewhat fleſhy, of a bright green. *Flowers* terminal and axillary, ſeſſile, ſolitary, yellowiſh-white.

Theſe are the only two ſpecies known to us, and indeed the latter is adopted entirely on the authority of Swartz.

HILLIARD, Nicholas, in *Biography*, a portrait-painter, who ſtudied and imitated the works of Hans Holbein. He was the ſon of Nicholas Hilliard, a tradeſman at Exeter, and was born in that city in 1547. He had the honour of painting the two rival queens, Elizabeth and Mary, queen of Scotland. He never obtained the ſolidity and truth of Holbein in his works; his colour is weaker, and his drawing not ſo free nor true; yet he wrought with great neatneſs, enriched his pictures with pearls and jewels, touched with great delicacy and ſpirit; and the hair and beards of his portraits are painted in fine lines, and not, like Holbein's, ſoft and broad. He was very much employed by the nobility and gentry, and was admired and highly prized in his time. Enjoying his reputation to the age of 72, he died in 1619.

HILLIGENHAVEN, in *Geography*, a town of the duchy of Holſtein, ſituated on the Baltic; 37 miles N. of Lubeck.

HILLOCK, a name often applied to a ſmall ſort of hill, as well as to little riſings occaſionally met with in ſward lands, that are cauſed by ants and other animals. See Mount.

Hillock-*ore*, in *Mining*, is a bad ſort of ſmitham ore, which is dreſſed from the refuſe vein-ſtuff on the mine-hillocks in Derbyſhire, and is ſometimes called pippin ore.

Hillocks, are the conical heaps of rubbiſh drawn from the lead-mines, and which uſually ſurround the tops of the ſhafts; the following mines in Derbyſhire have prodigious large hillocks of feaigh, or white vein-ſtuff, *viz.* Bondog-hole, in Middleton, by Wirkſworth; Gang, in Cromford; Gregory, in Overton; Hill-top, in Middleton, by Weſt Hucklow-edge, in Great Hucklow; Moſs-rake, in Bradwell; Samuel, on Middleton moor, near Wirkſworth, &c.; ſee Mr. Farey's liſt of mines, in his Report on Derbyſhire, vol. i. The refuſe of mines, or hillock-ſtuff, poiſons fowls kept on or near it, by the ſmall particles of lead-ore which they pick up along with their food.

HILLOCKY, a term ſignifying full of ant-hills.

HILLS, *Lake of the*, in *Geography*, a lake of North America, N. lat. 58° 36′, into which the Elk river diſcharges itſelf. See Athabasca and Chepewyan.

HILLSBOROUGH, a market and poſt-town in the county of Down, province of Ulſter, Ireland. It is a well built and thriving town, the property of the marquis of Downſhire, who has a houſe in it. There is a magnificent church, built by the late earl of Hillſborough, grand-father of the preſent marquis, to whoſe exertions the town was much indebted for its flouriſhing ſtate. It was formerly a borough which returned two members to parliament; but, like many others, loſt its privilege on the Union. The magiſtrates are a ſovereign and deputy ſovereign, and the marquis of Downſhire, who takes from it his title of earl, is hereditary conſtable of the fort. Hillſborough is 69½ miles N. by E. from Dublin, and 20 miles S.W. from Belfaſt. N. lat. 54° 26′. W. long. 6°.

Hillsborough, an iſland on the Labrador coaſt, on a bay at the head of which is Nain. N. lat. 57° 20′. W. long. 61° 20′.—Alſo, a county of America, in New Hampſhire, bounded N. by Grafton county, S. by the ſtate of Maſſachuſetts, W. by Cheſhire, and E. by Rockingham county; and containing 43,899 inhabitants, whoſe chief employment is agriculture. The chief towns are Amherſt and Hopkinton.—Alſo, a poſt-town in the before-named county, ſituated on the northern head branches of Contocook river, about eighteen or twenty miles W. of Concord; incorporated in 1772, and containing 1311 inhabitants.—Alſo, a townſhip in Somerſet county, New Jerſey, which contained, in 1790, 2201 inhabitants; 15 miles W. of Brunſwick.—Alſo, one of the middle diſtricts of North Carolina, bounded N. by the ſtate of Virginia, S. by Fayetteville diſtrict, E. by Halifax, and W. by Saliſbury, and comprehending the counties of Granville, Perſon, Caſwell, Orange, Wake, Chatham, and Randolph. It contains 80,012 inhabitants, of whom 22,198 are ſlaves. The chief town is Hillſborough.—Alſo, the town laſt-mentioned, capital of the diſtrict of its name, ſituated in Orange county, on the N. ſide of Eno river, in an elevated, fertile, and healthy country, and containing about 80 houſes, a court-houſe, a gaol, and an academy; 180 miles W.N.W. of Newbern, and 452 S.W. by S. of Philadelphia.—Alſo, a poſt-town in Loudon county, Virginia; 33 miles from Waſhington.—Alſo, a river of Eaſt Florida, which runs into the gulf of Florida, N. lat. 27° 36′. W. long. 81° 30′.—Alſo, another river of Eaſt Florida, which runs into the gulf of Mexico, N. lat. 28° 10′. W. long. 82° 30′.

Hillsborough *Bay*, a bay on the N. coaſt of the iſland of Dominica, formed at the mouth of a river of the ſame name. N. lat. 15° 42′. W. long. 62° 22′.—Alſo, a bay on the S. coaſt of the iſland of St. John, in the gulf of St. Lawrence. N. lat. 46° 10′. W. long. 62° 40′.

Hillsborough, *Cape*, a cape on the N.E. coaſt of New Holland. S. lat. 20° 56′. E. long. 148° 44′.

HILLSDALE, a poſt-town in Columbia county, New York, containing 4702 inhabitants; 15 miles E. of Hudſon city.

HILLTOWN, or Hilton, a ſmall town near the centre of Cheſter county, Pennſylvania; 28 miles W. of Philadelphia.—Alſo, a townſhip of Bucks county, in the ſame ſtate, having 1154 inhabitants.

HILLY Land, in *Agriculture*, that deſcription of ground which is much raiſed into hills. This ſort of land requires much care and attention in its cultivation, eſpecially in the ploughing, ſowing, and working of the more elevated parts. See Husbandry, Ploughing, and Tillage.

HILO, in *Geography*, a river of Chineſe Tartary, which runs into the ſea of Japan, N. lat. 42° 54′. E. long. 134° 31′.

HILONGOS, a town on the W. coaſt of the iſland of Leyta. N. lat. 10° 25′. E. long. 124° 40′.

HILPOLTSTEIN, a town of Germany, in the territory of Nuremberg; 17 miles N.N.E. of Nuremberg.—Alſo, a town of Bavaria, in the principality of Neuburg; 27 miles N. of Neuburg.

HILSAH, a town of Hindooſtan, in Bahar; 17 miles W. of Bahar. N. lat. 25° 18′. E. long. 85° 28′.

HILSBACH, a town of Germany, in the palatinate of the Rhine; 20 miles E. of Spire.

HILTERS, a town of Germany, in the biſhopric of Fulda; 14 miles E. of Fulda.

HILTON, John, in *Biography*, an Engliſh muſician and publiſher of muſic during the reigns of queen Elizabeth, James, and Charles I.; who, though he furniſhed a madrigal in the "Triumphs of Oriana," 1601, is found active as a compoſer and editor fifty years after.

He was a bachelor in muſic of the univerſity of Cambridge, organiſt of St Margaret's Weſtminſter, and alſo clerk of that pariſh. Though he began to flouriſh in the latter end of queen Elizabeth's reign, his genius for compoſition did not much expand, at leaſt publicly, during the next reign; though early in that of Charles I. he publiſhed "Fa Las" for three voices, and in 1652, an excellent collection of catches, rounds, and canons, for three and four voices, under the quaint title of "Catch that catch can;" among which there are many by himſelf, that were deſervedly admired by his cotemporaries, and which ſtill afford great pleaſure to the lovers of this ſpecies of humorous and convivial effuſions. He died during the Protectorſhip, and was buried in the cloiſter of Weſtminſter Abbey. He is ſaid to have had an anthem ſung in that church, before his body was brought out for interment; but as not only the cathedral ſervice was ſuppreſſed during this period, but the liturgy itſelf and every ſpecies of choral muſic, the fact ſeems unlikely and ill-founded.

Hilton *Head*, in *Geography*, an iſland of S. Carolina; W. and S.W. of which lie Pinckney's, Balls, Dawfuſkie's, and ſome ſmaller iſlands; and between theſe and Hilton Head are Calibogie river and ſound, which form the outlet of May and New rivers.

Hilton's *Point*, lies in Piſcataqua river, New Hampſhire, and is the ſpot where the united ſtreams of Newichawannock and Cochecho rivers meet the weſtern branch, and form the Piſcataqua. The courſe of the river, from thence to the ſea being about ſeven miles, is ſo rapid, that the water never freezes.

HILUM, in *Botany*, the *Scar* or *Eye*, is that particular part of the ſeed attached to the ſeed-veſſel, through which nouriſhment paſſes for the ſupport of the internal parts. It is extremely viſible in the bean, and as all the veſſels belonging to the ſeed are found to meet in this point, and to divaricate from it, they muſt be intimately connected with the inner ſurface of the *hilum*. This point is often ſtrongly contraſted in colour with the reſt of the ſeed, as is the caſe in *Cardioſpermum*, *Dolichos*, &c. "In deſcribing the form or various external portions of any ſeed, the *hilum* is always to be conſidered as the baſe. When the ſeed is quite ripe, the communication through this channel is interrupted: it ſeparates from the parent plant without injury, a ſcar being formed on each. Yet the *hilum* is ſo far capable of reſuming its former nature, that the juices of the earth are imbibed through it previous to germination."

HIMANGO, in *Geography*, a town of Sweden, in the government of Waſa; 25 miles N.E. of Gamla Karleby.

HIMANTIA, in *Botany*, from ἱμας, ἱμαντος, *a ſtrap or thong of leather*. Perſoon. Syn. 703.—*Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eſſ. Ch. Creeping, villous, branched and fibrous.

1. H. *domeſtica*.—Very large, browniſh, inclining to violet, ſoft, cohering into a membranous ſubſtance.

This pernicious fungus is found occaſionally in houſes, inſinuating itſelf, ſometimes to the extent of an ell, amongſt wrought wood, which it deſtroys.

2. H. *ſulphurea*.—Pale ſulphur-coloured, cottony, formed of roundiſh, entangled, branched fibres.—On the trunks of Fir-trees.

3. H. *candida*.—Paraſitic on leaves, tender, white; dilated like a feather at the top.—This is the *Byſſus candida* of Hudſon, p. 607; B. tenerrima villoſa et elegantiſſimè ramuloſa; Dill. Muſc. 7. t. 1. f. 15, A; frequent among decayed leaves, as thoſe of hawthorn, in moſſy dells in winter. It much reſembles Mr. Dillwyn's *Conferva nivea*, Syn. n. 59. t. C. Perſoon mentions a larger and more unconnected variety, found on dry branches

4. H. *lateritia*. (Clavaria filiformis; Bulliard. t. 448, f. 1.)—Wavy, ſomewhat branched, unconnected, red-brown; its ſummits ſwelling, whitiſh.—Found in France, on half-rotten leaves. It is deſcribed by Bulliard as ſometimes brown, ſometimes greyiſh-brown, but moſtly of a brick colour.

5. H. *umbrina*.—Fibrous, tender, villous, dark brown.—Found rarely on dry fir wood. Diſtinct from *Rhizomorpha corticalis*.

6. H. *farinacea*.—Red brown, dry, with a whitiſh powder; its fibres depreſſed.—Found on wood and branches of trees. Ludwig.

HEMANTOPUS, *Long-legged Plover*, in *Ornithology*. See Charadrius *Himantopus*.

HIMANTOSIS, in *Surgery*, a relaxation and lengthening of the uvula, which hangs down like a thong of leather, ἱμας, from which the word is deduced, having this latter ſignification.

HIMAS, the ſame as *Himantoſis*.

HIMAUS, or Imaus, in *Geography*. See Himmaleh.

HIMERA, in *Ancient Geography*, a town of Sicily, W. of Cephalenis, at the mouth of a river of the ſame name, now called *Salſo*. It is ſaid to have been founded by a colony of Zanclians, about the year of Rome 104. It was deſtroyed by the Carthaginians under Hannibal, who took the place by aſſault, razed it to its foundation, and treated the inhabitants with great cruelty, in the year of Rome 350. Near this city were baths, called "Himeriæ Thermæ."—Alſo, a town of Libya.

HIMIELA, La, in *Geography*, a town of Spain, in the province of Jaen; 12 miles E. of Ubeda.

HIMMALEH, anciently called *Emodus*, *Himaus*, or *Imaus*, a range of mountains in Aſia, extending from the Ganges, above Sirinagur, to Caſhmere, and ſeparating Caſhmere and the dependencies of Hindooſtan from Great Thibet, and Caſhgar from Little Thibet. Himmaleh is a Sanſcrit word, which ſignifies "ſnowy;" and the ancient appellations were probably derived from this term, to which Pliny ſeems to refer, when he ſays, "Imäus, incolarum lingua nivoſum ſignificante." This ridge of mountains appears to incline, in its northern courſe, towards the continuation of Hindoo-Kho, and even to join it. Here then, we are to imagine, an extenſive tract, of a triangular form, whoſe baſe of 200 miles or more, is a line drawn from Caſhmere to the eaſtern confines of Anderab; and whoſe ſides are the continuation of Himmaleh on the E., and that of Hindoo-Kho on the W. This ſpace contains, amongſt other countries, thoſe of Little Thibet (or Balti-ſtan), and Sakita; the *Byltæ* and *Sacæ* of Ptolemy; as alſo Kuttore, which anſwers to the *Comedi* of the ſame geographer; it alſo contains the ſources of the Indus. From the deſcriptions of *Little Thibet* and *Kuttore* (which ſee) we may conclude, that this whole ſpace is mountainous, and that its general level is far elevated above the countries on either ſide of it. We have no particular information, ſays major Rennell, reſpecting the poſition of the range of mountains which forms the baſe, or ſouthern ſide of the triangle; but circumſtances lead us to conclude, that the higheſt of theſe mountains are far removed from the northern frontier of the provinces, ſubject to, or commonly regarded as a part of Hindooſtan; and that the mountains which properly conſtitute the boundary of Hindooſtan, towards Kuttore (or Caferiſtan), commence in the parallel of Caſhmere, or about 34½ degrees; and extending weſtward from that celebrated country, ſeparate Puckholi, Sewad, and Bijore on the ſouth, from Caferiſtan on the north; and advancing from thence to a junction with mount Hindoo-Kho, in the line between Cabul and Anderab, ſeparate Lumghan, which appears to have been the ancient frontier of Cabul, from thoſe diſtricts, which, after the time of Baber, were added to, and have ſince become a part of the province of Cabul; according to its defined limits in the Ayin-Acbaree. On the north of this range, the whole country may be regarded as mountainous; on the ſouth the mountainous tract is confined chiefly to Sewad, Bijore, Teerah, and a part of Puckholi. (Rennell's Mem.) By Col. Crawford's obſervations, a peak of Himmaleh, ſeen from Patna, exceeds 20,000 feet above Nipal, which is probably 5000 feet above the ſea.

HIMMUTNAGUR, a town of Bengal; 25 miles N.E. of Purneah.

HIMS, a town of Arabia, in the province of Lachſa, near the Perſian gulf; 50 miles N. of Lachſa.

HIMTABADS, a town of Bengal; 25 miles W. of Dinagepour.

HIM-TCHAN, a town of China, of the third rank, in Pe-tche-li; 50 miles S.W. of Pao-ting.

HIN, a Hebrew meaſure, containing the ſixth part of an epha; or one wine gallon and two pints.

Hin, in *Geography*, a city of China, of the ſecond rank, in Chen-ſi. N. lat. 38° 27′. E. long. 112° 22′.

HINA, a town of Mexico, in the province of Yucatan; 12 miles N. of Campeachy.

HINAGIE Islands, three or four iſlands in the Indian ſea, near the coaſt of Africa. S. lat. 6° 50′.

HINATOAN, a town on the E. coaſt of the iſland of Mindanao. N. lat. 8° 12′. E. long. 126° 18′.

HINCHA, or St. Jean de Goava, a town in the iſland of Hiſpaniola. N. lat. 19° 14′. W. long. 72° 42′.

HIN-CHANG, a town of China, of the third rank, in Kiang-nan; 25 miles W.N.W. of Cheou.

HINCHINBROKE, Cape, a cape ſo called by capt. Cook, on the W. coaſt of North America, at the entrance into Prince William's ſound; within which is an anchoring place, in eight fathoms water, with a clayey bottom, at about a quarter of a mile from the ſhore. N. lat. 60° 15′. E. long. 213°.

HINCHINBROOK Island, one of the New Hebrides in the Southern Pacific ocean, a little to the north of Sandwich iſland; about ſix miles in circumference.—Alſo, an iſland in the S.E. part of Prince William's ſound, near the W. coaſt of North America. Its form is triangular; it has a large bay on its N. coaſt, and is above 48 miles in circumference. N. lat. 60° 24′. E. long. 213° 50′ to 114° 24′.

HINCKLEY, a market town and pariſh in the hundred of Sparkenhoe, Leiceſterſhire, England, is ſituated near the borders of Warwickſhire. Soon after the conqueſt it was created a barony, and held by Hugh de Grenteſmaiſnel, who erected a ſtately caſtle and a pariſh church within this domain. "The ruines of the caſtle," ſays Leland, "now longying to the king, ſumtyme to the earl of Leyrceſter, be a five miles from Leyrceſter, and in the borders of Leyrceſter foreſt, and the boundes of Hinckeley be ſpatious and famous there." Even the earth-works of the caſtle are now nearly levelled. The ditch and town-wall may however be traced in many places, and alſo the veſtiges of what are called two Roman works: a mount near the river, and the ruins of a bath adjoining the church. A priory was founded here, according to Tanner, by Robert Blanchmaines, and according to Dugdale, by Boſſu, the father of Robert; but Mr. Nichols controverts both thoſe claims, and aſcribes it to Hugh de Grenteſmaiſnel, who gave the priory, with the appropriation of the pariſh church, to the abbey of Lira in Normandy. This priory, like all foreign cells, was often ſeized by the crown during the wars with France, and was wholly ſuppreſſed by Henry V. The pariſh of Hinckley is of very great extent, and includes Stoke-Golding, Dadlington, Wyken, and The Hyde, which, though diſtinct villages, (the latter being in the county of Warwick,) are conſidered as hamlets of Hinckley. The town, under its original lords, certainly enjoyed the privileges of a borough; but being connected with the houſe of Lancaſter, and taking a decided part on that ſide in the civil conteſt; thoſe privileges, whatever their extent might be, became forfeited to the conquering monarch of the houſe of York. The town is now divided into the borough, and the bond without. The limits of the former were anciently thoſe of the town; which has been extended by the ſucceſſive addition of four ſtreets. The civil government is veſted in the mayor, conſtables, and headboroughs. The aſſizes for the county were formerly held here; and here were a gaol and a gallows. The pariſh church of Hinckley is an ancient edifice; the body of it is probably to be aſcribed to the thirteenth century; the weſt door reſembles thoſe of the time of Edward I. or II.; the window immediately over it is ſuppoſed to be an improvement made about the reign of Edward IV.; at which period, the building of the ſteeple, which is 40 yards high, may, with probability, be dated. To the church of Hinckley four chapels were formerly annexed, that of Stoke, (now a pariſh church,) that of Dadlington, and thoſe of Wyken and Hyde, which have been long ſince demoliſhed. The ancient chapel of Stoke was taken down at the beginning of the fourteenth century, by ſir Robert de Champaine, by whom the preſent church was then founded. The chapel of Dadlington bears evident marks of antiquity. Beſides theſe places of worſhip on the eſtabliſhment, there are in Hinckley five meeting-houſes for Preſbyterians, Independents, Quakers, Baptiſts, and Methodiſts; and a chapel for Roman Catholics. The trade of the town has been greatly augmented by the introduction of the ſtocking manufacture. The firſt frame was brought here before the year 1640, by William Iliffe, and is ſaid to have coſt him ſixty pounds; which muſt have been a very conſiderable ſum at that time, as the price of a good frame is not more at preſent than fifteen guineas. With this ſingle frame, which, with the help of an apprentice, he kept conſtantly working night and day, he gained a comfortable ſubſiſtence for his family. The manufacture is now ſo extenſive, that a larger quantity of hoſe is ſuppoſed to be made here than in any other town in England. Nottingham has more frames; but many of thoſe being employed in the fineſt ſorts of ſilk and cotton, the number of ſtockings there made is leſs than at Hinckley, where the frames are generally employed on ſtrong ſerviceable hoſe, of a lower price, in cotton, thread, and worſted. The number of frames in the town and adjacent villages is computed at upwards of 1200, which furniſh employment for nearly 3000 perſons. Hinckley is 100 miles diſtant from London; has a reſpectable market on Mondays, and ſeven annual fairs. The population of the town and its dependencies, which has been progreſſively increaſing, was returned to parliament in the year 1801 as 5686, inhabiting 1059 houſes. At a ſhort diſtance from the town is a ſpring, called The Holy Well, originally dedicated to the Virgin Mary, and once known by the name of Our Lady's Well. Nichols's Hiſtory, &c. of Leiceſterſhire.

In 1808, a new organ, which is a beautiful ornamental piece of mechaniſm, was ſet up in Hinckley church, by Mr. G. P. England of Tottenham-court road. It was erected by a liberal ſubſcription, and coſt 500 guineas. It has 21 ſtops, and contains 1370 pipes.

HIND, a female ſtag of the third year. See Hunting.

Hind-*calf*, a female hart of the firſt year. She fawns in April and May. Her fleſh is ſofter than that of a hart, but not ſo ſavoury, and is dreſt after the ſame manner. If it be roaſted it ought to be larded, dipped in a marinade or pickle, and moiſtened while it is roaſting. See Hunting.

Hind-*Hand*, in the *Manege*. See Hand.

HINDAK, in *Geography*, a town of Aſiatic Turkey, in Natolia; 25 miles S.W. of Boli.

HINDELOOPEN, a ſea-port town of Holland, in the department of Frieſland, ſituated on the Zuyder-ſee. It has no walls, and its harbour is ſmall. It is governed by five burgo-maſters, and ſix eſchevins. The inhabitants are chiefly employed in fiſhing, and building ſmall veſſels; 21 miles S.W. of Leuwarden. N. lat. 51° 58'. E. long. 5° 23'.

HINDENI Homines, formed from the Saxon *hindene*, a *ſociety* or *company*, anciently ſignified a ſociety, or claſs of men.

In the time of our Saxon anceſtors, all men were ranked into three claſſes, or *hindenes*; the *loweſt*, the *middle*, and the *higheſt*; and they were valued according to the claſs they were in; that in caſe an injury were done by any one, ſatisfaction might be made according to the value or worth of the man it was done to.

The *loweſt* were thoſe who were worth ten pounds, or two hundred ſhillings; called *viri ducentini*, or *twyhyndemen*, and their wives, *twyhyndas*.

The *middle* were valued at ſix hundred ſhillings; and were called *ſixhyndemen*, and their wives *ſixhyndas*.

The *higheſt* were valued at twelve hundred ſhillings; and were called *twelvehyndemen*, and their wives the *twelvehyndas*.

HINDENNY, or Endri, in *Geography*, a river of Hindooſtan, which paſſes by Adoni, and between Biſnagur and the Kiſtnah, falls into the Toombuddra.

HINDERAA, a town of Norway, in the dioceſe of Chriſtianſand; 20 miles N. of Stavanger.

HINDERABI, or Andarvia, an iſland in the Perſian gulf, about three or four miles long, and one broad, ſeparated from the coaſt of Perſia by a channel half a league acroſs, with depth of water from ſeven to 15 fathoms, and a muddy bottom. N. lat. 26° 44'. E. long. 54°.

HINDERSOE, a ſmall iſland in the N. part of the gulf of Bothnia. N. lat. 65° 38'. E. long. 22° 24'.

HINDIA, a circar of Hindooſtan, in Candeiſh, bounded N. by Bopal, E. by Kerleh, S. by the Taptee river, and W. by Bejapour. Its chief towns are Hindia, Hurdah, Huſſingabad, and Barawnay.—Alſo, the capital of the forementioned circar, ſituated on the Nerbudda; ſix miles E.S.E. of Indore. N. lat. 22° 35'. E. long. 77° 10'.

HINDMUND, or Heermund, a large inland river of Perſia, in the province of Segiſtan, which riſes from two widely ſeparated ſources, one in the mountains of Gaur, a part of the Hindoo-Kho, and the other far to the ſouth from the mountains of Gabelabad. Theſe ſtreams join not far to the E. of Boſt, whence the river purſues a weſterly courſe, and, according to the account of Otter, very ſoon divides into many branches, which are loſt in the central deſarts of Perſia. Our geographers, on the contrary, ſuppoſe that the Hindmund paſſes by Zarang into the ſea of Zerch. Pinkerton.

HINDOE, an iſland in the North ſea, near the coaſt of Norway, about 150 miles in circumference. N. lat. 68° 36'.

HINDON, a market-town and borough in the county of Wilts, England, is noted in the annals of parliamentary hiſtory, and borough intrigues, for the conteſted elections that have occurred here. It is deemed an open borough, and the right of election veſted in the bailiff and all the inhabitants paying ſcot and lot; the number of which amounts to about 210. A notorious ſcene of bribery and corruption, reſpecting this borough, was developed before a committee of the houſe of commons in 1775, when it was determined, that out of four candidates, neither of them was duly elected a burgeſs, and that the ſpeaker ſhould not iſſue his warrant for a new writ. The committee were alſo of opinion that it would be expedient to dis-franchiſe the ſaid borough. A bill was brought into parliament for this purpoſe, but was thrown out on account of ſome items of informality. A new bill was afterwards prepared, and read twice during the ſeſſions of 1775, but being ſtrongly oppoſed by counſellors, petitioners, &c. it was not paſſed that year. A third bill was brought in early in the following ſeſſions, which was alſo relinquiſhed, in conſequence of the haraſſing oppoſition made to it. A new writ was then iſſued, and two members again returned for the borough. It is conſidered to be the property, and under the influence of the Beckford family, of Fonthill. A particular account of the preceding caſe, and proceedings, is given in the Hiſtory of Boroughs, vol iii. The firſt time it returned members to parliament was in the 27th year of Henry VI. Hindon conſiſts principally of one long ſtreet, built on the declivity of a gentle hill; and is ſurrounded by part of the Downs. Here are a ſmall weekly market held every Thurſday, and two annual fairs. About two miles S. of the town is Fonthill-Abbey, the ſeat of William Beckford, eſq. The building is ſingular, and its ſituation, ſecluſion, and hiſtory, are alſo replete with ſingularities. On the apex of a lofty hill, nearly the whole of which is covered with plantations, is a large building, aſſuming the exterior forms and character of a cathedral church. A lofty arched porch, an octagonal tower, with turrets, pinnacles, and gables, are ſeen riſing above the trees, and together conſtitute a maſs which may be ſeen at the diſtance of ſeveral miles in almoſt every direction. The interior of this manſion is however more an object of curioſity, and more calculated to excite admiration than the exterior. All the rooms are fitted up in a ſtyle imitative of the elaborate carvings, tabernacle work, &c. of the moſt decorated church architecture; to heighten the effect of which, paintings, gilding, ſculpture, and the moſt coſtly articles in upholſtery, &c. are all brought together. The richeſt treaſures of the fine arts, and literature, are alſo enſhrined within the walls; yet theſe curioſities and rarities are ſecluded from public view, and the whole plantations and houſe are environed by a high wall, ſurmounted by a cheveaux de friſe of iron.

HINDOO-KHO, or *Indian Caucaſus* of Alexander, part of a long ridge of mountains in Aſia, which forms the N.W. boundary of Cabul, and ſeparates it from Balk and Badakſhan. This ridge takes a N.E. direction, between Bamian and Anderab, after which it paſſes between the E. and N.E., until it appears again at the ſources of the Jihon, (or Oxus,) at about 100 miles to the E. of the city of Badakſhan; and from thence paſſing on to the N., it gives riſe alſo to the Sihon (on Jaxartes.) (See Himmaleh.) The city of Cabul is ſituated near the foot of this mountain. (See Cabul.) Between the mountains of Hindoo-Kho and thoſe of Candahar, the country takes the form of an extenſive valley, from Cabul to the borders of Koraſan. The river Heermund or Hirmend iſſues from the north of theſe mountains, and the waters of Cabul from the eaſt. Hindoo-Kho is continued weſtward, under the name of *Gaur* (which ſee), and in poſition anſwers to *Parapamiſus*.

HINDOOS, the inhabitants of that part of India, denominated Hindooſtan, who profeſs the religion of the Bramins. (See BRACHMANS.) They are called *Gentoos*. For an account of them, ſee that article. See alſo the next article.

HINDOOSTAN, a country of Aſia, which, by the people of modern Europe, has been underſtood to mean the tract ſituated between the rivers Ganges and Indus on the E. and W.; the Thibetian and Tartarian mountains on the N; and the ſea on the S. But ſtrictly ſpeaking, the extent of Hindooſtan is much more circumſcribed; and the name ought to be applied only to that part of the above tract, which lies to the N. of the parallels of 21° or 22°. The Nerbuddah river is, indeed, the reputed ſouthern boundary of Hindooſtan, as far as it goes; and the ſouthern frontiers of Bengal and Bahar compoſe the remainder of it. The countries on the S. of this line, according to the Indian geographers, go under the general name of DECCAN; and compriſe nearly one-half of the tract generally known by the name of the Mogul empire. But as the term Hindooſtan has been applied in a lax ſenſe to this whole region, it may be neceſſary to diſtinguiſh the northern part of it, by the name of Hindooſtan *Proper*. This tract has indeed the Indus, and the mountains of Thibet and Tartary, for its weſtern and northern boundaries; but the Ganges was improperly applied as an eaſtern boundary, as it interſects in its courſe ſome of the richeſt provinces of the empire; while the Burrampooter, which is much nearer the mark as an eaſtern boundary, was utterly unknown. In this circumſcribed ſtate, the extent of Hindooſtan *proper* is about equal to France, Germany, Bohemia, Hungary, Switzerland, Italy, and the Low Countries, collectively; and the Deccan and Peninſula are about equal to the Britiſh iſlands, Spain, and Turkey, in Europe. See DECCAN.

The learned Mr. Wilkins aſſured major Rennell, that no ſuch words as "Hindoo," or "Hindooſtan," are to be found in the Sanſcrit dictionary. The people among whom the Sanſcrit language was vernacular, ſtyled their country "Bharata." The Hindoos, however, call their country "Medhyama;" and they pretend that it was the portion of "Bharat;" one of the nine brothers, whoſe father had the dominion of the whole earth. (See Aſiatic Reſearches, vol. i. p. 419.) It is then probable, that the word "Hind" furniſhed that of India to the Greeks; and the termination *Stan*, ſignifying country in the Perſic, is of more modern date. It has happened, on this as well as ſimilar occaſions, that the name "India" has been applied not only to the country originally deſigned by it, but to others adjacent to and beyond it; for the countries between Hindooſtan and China came to be called the *further* India, or India *extra Gangem;* whereas Hind, or India, properly belonged only to the country of the people called Hindoos; or thoſe of India *intra Gangem*. The name is as ancient as the earlieſt profane hiſtory extant; and this circumſtance ſerves, as well as others, to prove the high antiquity of the Perſian language. For other appellations of the Hindoos and Hindooſtan, ſee GENTOOS.

HINDOOSTAN, *Hiſtory of*. Hindooſtan, under one appellation or another, has laid claim to very high antiquity; but the earlier period of its hiſtory is involved in great obſcurity and uncertainty. If we may credit the relations of ſome hiſtorians, the enterpriſing ambition of Seſoſtris, ſuppoſed king of Egypt about 1485 years B. C., induced him to fit out a fleet of 400 ſhips in the Arabian gulf, which conquered all the countries ſtretching along the Erythrean ſea to India. At the ſame time, his army, led by himſelf, marched through Aſia, and ſubjected to his dominion every part of it as far as to the banks of the Ganges; and croſſing that river, advanced to the eaſtern ocean. (Diod. Sic. lib. i.) Strabo, however, rejects the accounts of the Indian expedition of Seſoſtris; and he not only aſſerts, in the moſt explicit terms, that this monarch never entered India (lib. xv.), but he ranks what has been related concerning his operations in that country with the fabulous exploits of Bacchus and Hercules. Arrian alſo concurs in the ſame ſentiments with reſpect to the exploits of Seſoſtris in India. (Hiſt. Ind. c. 5. Arrian, Exped. Alex.) And as Herodotus ſeems to have derived his information concerning India, not from the Egyptians, but from the Perſians, it is probable that in his time there was little intercourſe between Egypt and India. Dr. Robertſon, in his "Hiſtorical Diſquiſition concerning India," has ſuggeſted a variety of conſiderations which evince the improbability of any ſuch expedition as that of Seſoſtris into India. It is much more probable, that the Phœnicians, having wreſted from the Idumæans ſome commodious harbours towards the bottom of the Arabian gulf, held from theſe a regular intercourſe with India on the one hand, and with the eaſtern and ſouthern coaſts of Africa on the other. But as the diſtance from the Arabian gulf to Tyre was conſiderable, and the conveyance of goods by land tedious and expenſive, they took poſſeſſion of Rhinocolura, the neareſt port in the Mediterranean to the Arabic gulf; and thus they were forwarded, partly by land and partly by ſea, to Tyre. It is probable that Solomon's profitable traffic included that of India. As his kingdom extended from the Euphrates to the Red ſea, and to the borders of the Red ſea, (1 Kings, iv. 24.) it opened to him two of the great avenues to the eaſt, by the way of the Red ſea, and the Perſian gulf. Volney ſuggeſts, that the object which Solomon had in view, when he took poſſeſſion of Palmyra, was to uſe it as an emporium of the Eaſt India trade, by the way of the Perſian gulf, and the courſe of the Euphrates. This was about 1000 years before our era. Solomon's trade, however, was merely temporary.

The firſt and moſt authentic accounts of Hindooſtan are thoſe which are given us by Herodotus, who lived 113 years before the expedition of Alexander the Great. From him (l. iv. c. 42. 44.) we learn, that Darius, the ſon of Hyſtaſpes, explored regions of Aſia formerly little known. Having ſubjected to his dominion many of the countries which ſtretched S.E. from the Caſpian ſea towards the river Oxus, his curioſity was excited to acquire a more extenſive and accurate knowledge of India, on which they bordered. For this purpoſe he appointed Scylax of Caryandra to take the command of a ſquadron fitted out at Caſpatyrus, in the country of Pactya (the modern Pehkely), towards the upper part of the navigable courſe of the river Indus, and to fall down its ſtream until he ſhould reach the ocean. After employing two years and ſix months in this expedition, he gave ſuch an account of the populouſneſs, fertility, and high cultivation of that region of India, through which his courſe lay, as rendered Darius impatient to become maſter of a country ſo valuable. This he ſoon accompliſhed; and though his conqueſts in India do not ſeem to have extended beyond the diſtrict watered by the Indus, he levied a tribute which amounted to near a third part of the whole revenue of the Perſian monarchy. But neither the voyage of Scylax, nor the conqueſts of Darius, diffuſed any general knowledge of India. About 160 years after the reign of Darius Hyſtaſpes, Alexander the Great undertook his expedition into India. Accordingly he ſet out from Bactria, and croſſed that ridge of mountains, which, under various denominations, forms the "Stony Girdle" (to adopt the phraſe of oriental geographers)

geographers) that encircles Aſia, and conſtitutes the northern barrier of India; and thus he diſcovered the route which was taken by the ſubſequent invaders of this country, Tamerlane and Nadir Shah. After paſſing the mountains, he encamped at Alexandria Paropamiſana, not far from the mountains denominated the Indian Caucaſus by his hiſtorians, and now known by the name of *Hindoo Kho* (which ſee); and having ſubdued or conciliated the natives ſeated on the N.W. bank of the Indus, he croſſed the river at Taxila, now Attock. He then marched forward in the direct road towards the Ganges, and the opulent provinces that lay towards the S.E., now comprehended under the general name of Hindooſtan. But being oppoſed on the banks of the Hydaſpes by Porus, a powerful monarch of the country, and by ſome other Indian princes, he was diverted from his route, and obliged to turn more towards the S.W., and to march through one of the richeſt and beſt peopled countries of India, now called the *Panjab*, (which ſee). It was his intention to have purſued his march to the Ganges, and the fertile regions through which that river flowed; but his troops, having already ſuffered much, unanimouſly refuſed to advance farther, and Alexander was obliged to iſſue orders for marching back to Perſia. This memorable tranſaction took place on the banks of the Hyphaſis, which was the utmoſt limit of Alexander's progreſs in India; ſo that he did not traverſe the whole extent of the Panjab. Upon his return to the Hydaſpes, he found that the officers, with whom he had entruſted the charge, had aſſembled a numerous fleet, which he deſtined to ſail down the Indus to the ocean, and from its mouth to proceed to the Perſian gulf, that a communication by ſea might be opened with India and the centre of his dominions. The conduct of this expedition was committed to Nearchus; and he was accompanied down the river by Alexander himſelf with a very great and magnificent armament. The diſtance to the ocean was no leſs than 1000 Britiſh miles, and the navigation occupied nine months. Of the extenſive region through which they paſſed, a conſiderable portion, particularly the Upper Delta, ſtretching from the capital of the ancient Malli, now Moultan, to Patala, the modern Tatta, is diſtinguiſhed for its fertility and population. Alexander, having accompliſhed this object, led his army back by land to Perſia; and Nearchus, after a coaſting voyage of ſeven months, conducted the fleet ſafely up the Perſian gulf into the Euphrates. With reſpect to the general ſtate of India we learn, that in the age of Alexander, though there was not eſtabliſhed in it any powerful empire, reſembling that which in modern times ſtretched its dominion from the Indus almoſt to Cape Comorin, it was even then formed into monarchies of conſiderable extent. From the memoirs of Alexander's expedition, preſerved by Arrian, we alſo derive the firſt authentic information concerning the climate, the ſoil, the productions, and the inhabitants of India; and it is remarkable that the deſcriptions given by Alexander's officers delineate what we now behold in India, at the diſtance of 2000 years. The ſtated change of ſeaſons, now known by the name of "Monſoons," the periodical rains, the ſwelling of the rivers, and the inundations occaſioned by them, and the appearance of the country during their continuance, are particularly mentioned and deſcribed. No leſs accurate are the accounts which they have given of the inhabitants, their delicate and ſlender form, their dark complexion, their black uncurled hair, their garments of cotton, their living entirely upon vegetable food, their diviſion into ſeparate tribes, or "caſts," the members of which never intermarry, the cuſtom of wives burning themſelves with their deceaſed huſbands, and many other particulars; in all which they perfectly reſemble the modern Hindoos. Alexander, however, explored only a ſmall portion of the vaſt continent of India. His operations did not extend beyond the modern province of Lahore, and the countries on the banks of the Indus, from Moultan to the ſea. In India, however, he founded two cities on the banks of the Hydaſpes, Nicæa and Bucephalia, and a third on the Aceſines, both navigable rivers, which, after uniting their ſtreams, fall into the Indus. By means of theſe cities he evidently intended to keep open a communication with India, not only by land but by ſea; and alſo by clearing the navigation of the Euphrates and Tigris, he propoſed that the valuable commodities of India ſhould be conveyed from the Perſian gulf into the interior parts of his Aſiatic dominions, while by the Arabian gulf they ſhould be carried to Alexandria and diſtributed to the reſt of the world. Seleucus, one of the ſucceſſors of Alexander, entertained high ideas of the advantages that might be derived from a commercial intercourſe with India, and with a view of ſecuring and extending them, he marched into the country, and advanced conſiderably beyond the utmoſt boundary of Alexander's progreſs. In order to obtain ſome knowledge of the country and the manner of its inhabitants, he ſelected Megaſthenes, who had accompanied Alexander in his expedition to India, and deputed him as ambaſſador to Palibothra, the famous capital of the Praſii, ſituated on the banks of the Ganges. Here he reſided ſeveral years, and was probably the firſt European who ever beheld that mighty river, far ſuperior to any of the ancient continent in magnitude, and no leſs diſtinguiſhed by the fertility of the countries through which it flows. By this journey and ſettlement of Megaſthenes, the Europeans gained an acquaintance with a large extent of country of which they had not hitherto any knowledge. From his writings the ancients ſeem to have derived almoſt all their knowledge of the interior ſtate of India, and the ample accounts of Diodorus Siculus, Strabo, and Arrian, appear manifeſtly to be a tranſcript of his words. But Megaſthenes, being fond of the marvellous, has unfortunately blended with the truths which he related many extravagant fictions, and diminiſhed our confidence in his other relations. The embaſſy of Megaſthenes to Sandracottus, and another of Daimachus to his ſon and ſucceſſor Allitrochidas, are the laſt tranſactions of the Syrian monarchs with India, of which we have any account. Nor can we fix with accuracy the time, or deſcribe the manner in which their poſſeſſions in India were wreſted from them. It is probable that they were obliged to abandon the country ſoon after the death of Seleucus. When Bactria, originally ſubject to Seleucus, became an independent ſtate about 69 years after the death of Alexander, the link of the chain that connected India with Syria was broken. The Indian trade was about the ſame time transferred from Tyre to Alexandria in Egypt, where it flouriſhed under the auſpices of the Ptolemies, (ſee Berenice,) until Egypt became a Roman province, and was continued on a more extenſive ſcale by the Romans themſelves; nor did it forſake Alexandria until the re-diſcovery of the paſſage by the Cape of Good Hope. This traffic opened to the Egyptians and Romans a knowledge of the coaſts and products of India. It is extraordinary, however, conſidering how much the detail of the coaſts was known to Ptolemy, that the general form of his map ſhould ſo much deviate from the truth; for he makes the coaſts between the Indus and Ganges to project only in a ſlight curve; whereas, they are known to form the ſides of a triangle, whoſe perpendicular almoſt equals its baſe; Cape Comorin being the apex of it. Whoever, ſays major Rennell, compares the proportional dimenſions of India, found in Diodorus Siculus, Pliny and Arrian, will find them tolerably juſt; and will be inclined to think that the worſt ſet of ancient maps of India has travelled down to us; and that Ptolemy, in conſtructing his map of that part, did not expreſs the ideas of well-informed people of his own time on that ſubject. Pliny was about 60 years before Ptolemy, and Arrian about 20 years after Ptolemy; their accounts of the dimenſions of India were taken from Eratoſthenes and Megaſthenes. Diodorus ſays, that India is 32,000 ſtadia from N. to S., and 28,000 from E. to W.; that is, the breadth is ſeven-eighths of the length. Arrian gives the meaſures collected by Eratoſthenes and Megaſthenes; and ſays, that India is bounded on the W. by the Indus; on the N. by a continuation of Mount Taurus, called in different parts Paro-pamiſus, Emodus, and Himaus; and on the S. by the ocean, which alſo ſhuts up the eaſtern parts of it. Few authors, (ſays he,) have given us any account of the people that inhabit towards the mouths of the Ganges, where Palibothra is ſituated. The diſtance from the mountains, at the head of the Indus, to its mouth, according to Eratoſthenes, is 13,000 ſtadia; and from the ſaid mountains to the eaſtern ſea, the extent is ſomewhat leſs; but as a huge tract of land runs out 4000 ſtadia into the ſea, (meaning the peninſula,) it may be reckoned 16,000 ſtadia; the diſtance from Palibothra to the weſtern extremity of India, meaſured along the great road, is 10,000 ſtadia; and the whole length, (that is, from E. to W.) is 20,000 ſtadia. Arrian, likewiſe, gives the meaſures according to Megaſthenes, who reckoned India 22,300 ſtadia from N. to S., and 16,000 broad from E. to W.; making that the breadth which Eratoſthenes reckons the length. Megaſthenes's proportion is, on the whole, according to major Rennell, the trueſt; for India is about 28 degrees of a great circle in length from N. to S.; or from the Indian Caucaſus to Cape Comorin; and about 20° in breadth from the Indus to the mouth of the Ganges; and reckoning from the moſt diſtant mouth of each river, it will be 22° in breadth. Thus we ſee that Arrian had as juſt an idea of the proportional dimenſions of India, as we had 40 years ago; for it was then reckoned narrower than the truth by at leaſt two degrees. Pliny gives the meaſures along the coaſts between the mouth of the Ganges and Pattala, (or Tatta,) in the mouth of the Indus at 3320 miles, *i.e.* according to Rennell, Roman miles of 1000 paces. The true meaſure of theſe coaſts, rejecting the ſinuoſities, and attending only to the general form, is 40 degrees of a great circle. Allowing, with M. D'Anville, 75 Roman miles to a degree, the above number of miles will amount to 44° inſtead of 40°, the true meaſure; but reckoning the pace at four feet 10.02 inches Engliſh, there ought to be $78\frac{1}{2}$ Roman miles to a degree, and thus the 3320 Roman miles will be 42°, or within $\frac{1}{21}$ part of the truth. Pliny, therefore, it is evident, knew nearly the form of the peninſula; and Ptolemy was ignorant of its general form, although he knew ſo much concerning the particulars.

Arrian's geograghy of India relates chiefly to the northern parts, or thoſe ſeen by Alexander and Megaſthenes; and his catalogue of rivers contains only thoſe that diſcharge themſelves into the Ganges or Indus.

It is unqueſtionable, that the Hindoo or Braminical religion was univerſal over Hindooſtan and the Deccan, before the time of Alexander's conqueſt, according to the accounts given us by Herodotus and Arrian. But though there might be an univerſality of religion, there were many diſtinct languages; and hiſtory, both ancient and modern, aſſures us that India was divided into a number of kingdoms or ſtates, from the time of Herodotus down to that of Acbar. There appears, however, to have been, generally, independently of theſe diviſions, a large empire or kingdom, which occupied the principal part of that immenſe valley or plain, through which the Ganges takes its courſe; the capital of which has fluctuated between Delhi and Patna, as the limits of the empire have varied. This kingdom was that of the "Praſii," and "Gangaridæ;" in the times of Alexander and Megaſthenes; which appears, by the ſtrength of its armies and the number of elephants trained to war, to have been very powerful. This kingdom, as major Rennell ſuppoſes, could not have been leſs in dimenſions than France, extending weſtward to the Panjab country, and including at leaſt part of Bengal; and, as Arrian deſcribes it, its ſtate was rich. The inhabitants were good huſbandmen, and excellent ſoldiers; governed by nobility, and living peaceably; their rulers impoſing upon them nothing harſh or unjuſt.

Major Rennell obſerves, that there is no known hiſtory of Hindooſtan (reſting on the foundations of Hindoo materials, or records,) extant, before the period of the Mahomedan conqueſts; for either the Hindoos kept no regular hiſtories, or they were all deſtroyed, or ſecluded from common eyes by the Pundits. The travels of Coſmas in the ſixth century (ſee COSMAS), and of the two Mahomedan travellers in the ninth, afford few materials for hiſtory; and but little can be gleaned from Marco Paolo, a Venetian nobleman, who croſſed the peninſula, and went up the weſtern ſide of it to Guzerat, in the 13th century. It is chiefly to Perſians that we are indebted for that portion of Indian hiſtory which we poſſeſs. The celebrated Mahomed Feriſhta, early in the 17th century, compiled a hiſtory of Hindooſtan, from various materials, moſt of which, according to Col. Dow, who tranſlated this hiſtory, were collected from Perſian authors. But the tranſlator allows, that the moſt valuable part of this hiſtory is that poſterior to the firſt Mahomedan conqueſts, about the year 1000. The firſt Mahomedan conqueror, who made any eſtabliſhments in Hindooſtan, was Mahmood, emperor of *Ghizni*; which ſee. In the year 1000 he entered Hindooſtan; and although in 1008 all the Hindoo princes, from the weſt of the Ganges to the river Nerbuddah, united againſt him, for the common defence of their religion, which he wiſhed to extirpate, and which he actually attempted to annihilate by the ſavage deſtruction of their temples, they were defeated. After ſeveral ſucceſsful but deſolating expeditions, Mahmood died in 1028, poſſeſſed of the eaſtern, and by much the largeſt part of Perſia; as well as, nominally, of all the Indian provinces from the weſtern part of the Ganges to the peninſula of Guzerat, and from the Indus to the mountains of Agimere; but the Panjab was the only part of it that was ſubjected to regular government under the Mahomedans; as being in the vicinity of the Ghiznian empire. As for the Rajpoots of Agimere, they ſtill preſerved their independence, among their rugged mountains, and cloſe vallies; and not only then, but, in a great meaſure, down to the preſent time; being, in reſpect of Hindooſtan, what the country of Switzerland is to Europe; but much more extenſive and populous. From Mahmood to Aurungzebe the Indian conquerors were contented with the nominal ſubjection of thoſe hardy tribes; among whom, military enthuſiaſm, grafted on religious principles, is added to ſtrength and agility of body; and this race is diſſeminated over a territory equal to half the extent of France, as it exiſted before the late revolution. It goes under the general name of Rajpootana; and is the original country of the founder of the Mahratta ſtate; whoſe ruler, about half a century ago, aſpired at univerſal empire in Hindooſtan. (See MAHRATTAS.) Upon the death of Mahomed Gori, in 1205, the

Indian part of the Ghiznian empire, then divided, fell to Cuttub, who founded the Patan or Afghan dynaſty in Hindooſtan. The Afghans originally inhabited the mountainous tract lying between India and Perſia, or the ancient Paropamiſus. (For their hiſtory, ſee Afghans.) Before Cuttub's elevation to the throne, he had carried his arms under Mahomed Gori, into Agimere and Guzerat. Lahore was, originally, his capital; but with a view of fixing the imperial reſidence nearer to the centre of his conqueſts, he removed to Delhi. The emperor Altumſh, who ſucceeded to the Patan throne in 1210, completed the conqueſt of the greateſt part of Hindooſtan proper. He appears to have been the firſt Mahomedan that made a conqueſt of Bengal; and it was during this reign (1221) that Gengiz Cawn, among his extenſive conqueſts, accompliſhed that of the empire of Ghizni; but he left Hindooſtan undiſturbed. About A. D. 1243, the Moguls, or Munguls, ſucceſſors of Gengiz, who poſſeſſed, or rather over-run the countries on the N. W. of Hindooſtan, made ſeveral irruptions into it; but it was not till more than 150 years afterwards, that, under Timur, or Tamerlane, they penetrated into the centre of India. The provinces of Hindooſtan were held rather as tributary kingdoms, than as provinces of the ſame empire; and they ſeldom failed to revolt when a favourable opportunity offered. Of the ſtate of the internal government of Hindooſtan, a judgment may be formed by the puniſhment inflicted on the Mewatti, or the Banditti tribe, which inhabit the hilly tracts within 25 miles of Delhi. In 1265, 100,000 of theſe wretches were put to the ſword, and a line of forts was conſtructed along the foot of their hills.

"Rebellions, maſſacres, and barbarous conqueſts," ſays major Rennell, "make up the hiſtory of this fair country (which, to an ordinary obſerver, ſeems deſtined to be the paradiſe of the world); the immediate effect of the mad ambition of conquering more than can be governed by one man: for the whole empire being portioned out to rapacious governors, who domineering over the governed, until their ſpirits were ſufficiently debaſed, were at laſt able to perſuade them, that their common intereſt lay in taking up arms, to render theſe governors independent."—"It would appear as if the warm climates, and more eſpecially the open countries, ſituated within them, were deſtined to be the ſeats of deſpotiſm; for that the climate creating few wants, and the ſoil being productive without any great exertion; the inhabitants of it do not poſſeſs thoſe energies that, in a cooler climate, prompt mankind to inveſtigate their natural rights, and to aſſert them. This, however, is a point that I ſhall not venture to decide on; although I believe it is a fact not to be diſputed, that throughout the known parts of the world, deſpotiſm prevails moſt in the warm climates. The Patan, Mogul, and Tartarian conquerors in Hindooſtan and China, however hardy at firſt, have, in a courſe of ages, ſunk into the ſame ſtate of effeminacy with their ſubjects; and, in their turn, have, with them, received a new maſter. Let thoſe who are in the habit of complaining of the ſeverity of a northern climate, reflect, that whatever phyſical evils it may produce, it matures the great qualities of the mind; and renders its inhabitants pre-eminent among their ſpecies; while a flowery poet, or a more flowery hiſtorian, is the moſt eminent production of the tropical regions." (See Climate.)

The Moguls, having gained acquiſitions in the provinces on the W. of the Indus, in conſequence of the neglect of the kings of Delhi, at length croſſed that river, and invaded the Panjab; and ſo formidable did they appear to Feroſe II., that ſome tribes of them were permitted to ſettle in that country. (A.D. 1292.) In 1293 this emperor projected, at the ſuggeſtion of Alla, governor of Gurrah, an attack upon the Deccan, a tract nearly equal in extent to what he actually poſſeſſed in Hindooſtan, and which extended from the ſhores of the Indus to the mouth of the Ganges, and from the northern mountains to Cattack, Sirong, and Agimere; the greateſt part of Malwa, with Guzerat and Sindi, being then independent. Alla, incited firſt by avarice, having ſucceeded in his object, depoſed and murdered the emperor, and took poſſeſſion of the throne in 1295, beginning his plan of conqueſt by the reduction of Guzerat; but while he was purſuing his conqueſts, the watchful and reſtleſs Moguls penetrated even to Delhi, and plundered its ſuburbs. Alla, having extended his victories and poſſeſſions, died in 1316. At this period all Hindooſtan proper was comprehended in the Patan empire (ſo called from the dynaſty in poſſeſſion of the throne), and the interior policy is ſaid to be ſo well regulated, that ſtrangers might travel through the empire in perfect ſecurity. Feroſe III., who ſucceeded in 1351, appeared more deſirous of improving the empire, after the defection of Bengal and the Deccan, &c. than of extending it by arms. Accordingly, canals and public works, for the improvement of agriculture and of the inland navigation, were his favourite objects during a reign of thirty-ſeven years. The Moguls made another irruption in 1357; and after the death of Feroſe, in 1388, rebellion and civil war, during a courſe of ſeveral years, prepared the empire for foreign ſubjection, and a minority in the perſon of Mahmood III., who ſucceeded in 1393, brought matters to a criſis. In this ſtate of things, Timur, who had already extended his empire over all the Weſtern Aſia and Tartary, turned his arms towards Hindooſtan in 1398. In the preceding year his grandſon Peer Mahomed had prepared the way by reducing the Panjab and Moultan; and before the cloſe of the year, he himſelf croſſed the Indus, and took poſſeſſion of Delhi without a battle. "This inhuman monſter," ſays Rennell, "who had credit enough with a poet of the (laſt) century, to be introduced on the ſtage, as a hero, poſſeſſing great and amiable qualities, obtained in Hindooſtan the title of "the deſtroying prince;" and was truly worthy of it, from the numerous maſſacres and exterminations executed under his immediate direction." He was rapid in his deſtructive movements; he ſpent little more than five months between the time of his croſſing and re-croſſing the Indus; and he appears to have paid more attention to ſeaſons than Alexander had done; as Timur choſe the fair ſeaſon for his expedition, whereas Alexander was in the field, in the Panjab, during a whole rainy ſeaſon. Timur, however, may be ſaid rather to over-run than to ſubject or conquer: for he did not diſturb the order of ſucceſſion in Hindooſtan, but left Mahmood on the throne, reſerving to himſelf the poſſeſſion of the Panjab country only; which his ſucceſſors did not long retain. During his life, which ended in 1405, he was prayed for in the moſques of Hindooſtan, and the coin was ſtruck in his name; but this might be more the effect of policy in the uſurpers of Mahmood's throne than the act of Timur. It does not appear that he carried much treaſure with him out of Hindooſtan. But Nadir Shah's acquiſition of the precious metals, at a later period, was great beyond all ideas of accumulation in Europe; and is only to be accounted for by the influx of thoſe metals from America, during that interval. The death of Mahmood happened in 1413; and with him ended the Patan dynaſty, founded by Cuttub in 1205. The throne was then filled by Chizer, a Seid, one of the race of the prophet Mahomed, whoſe poſterity occupied it until the year 1450, when Belloli, an Afghan of the tribe of Lodi, took poſſeſſion of it, on the abdication of Alla II., under whom all Hindooſtan fell into ſeparate governments. The ſon of Belloli recovered a conſiderable part of the empire, and in 1501 made Agra the royal reſidence. It was during this reign that the Portugueſe firſt accompliſhed the paſſage to India by the Cape of Good Hope. The empire fell again into utter confuſion under Ibrahim II. in 1526; and this paved the way for the conqueſt of Hindooſtan by Sultan Baber, a deſcendant of Tamerlane and of Gengiz Khan; who reigned over a kingdom compoſed generally of the provinces ſituated between the Indus and Samarcand. Diſpoſſeſſed of his dominions by the Uſbecs, he determined to try his fortune in Hindooſtan, whoſe diſtracted ſituation flattered his hopes of conqueſt. From Cabul, where he reſided, he undertook his firſt expedition acroſs the Indus, in 1518. In his fifth expedition (A.D. 1525) he defeated the emperor of Delhi, and put an end to the dynaſty of Lodi. Baber reigned only five years in Hindooſtan, during which time his chief employment was the reduction of the eaſtern provinces. His ſon Humaioon ſucceeded him in 1530; but though he was a prince of conſiderable abilities and great virtues, he was driven from his empire in 1541. During his expulſion, his ſon Acbar was born, whom we may reckon among the greateſt of the ſovereigns of Hindooſtan. The ſtate of this country was ſo unſettled, that no leſs than five ſovereigns appeared on its throne in the courſe of nine years. A ſtrong party in Hindooſtan invited Humaioon back; and he returned in 1554, but died in the following year. His good character facilitated the acceſſion of his ſon Acbar, who was about the age of fourteen years, in 1555, when his father died. For a general account of Acbar's character and reign, we ſhall refer to the biographical article AKBAR, and alſo to the hiſtory of Hindooſtan by Col. Dow. We ſhall here add ſome further particulars. As in the perſon of Baber, the line of Tamerlane firſt aſcended the throne of Hindooſtan, ſo in that of Acbar, the grandſon of Baber, it may be ſaid to have been eſtabliſhed. The conqueſt of their anceſtor, about a century and a half before, had no ſhare in effecting the preſent ſettlement. Baber was in reality the founder of the Mogul dynaſty; and from this event Hindooſtan came to be called the "Mogul" empire. The firſt years of Acbar's reign were employed in the reduction of the revolted provinces from Agimere to Bengal; and his conqueſts were ſecured by a proper choice of governors, by wiſe regulations, by an unlimited toleration of religion, and by a proper attention to the propenſities of the people; to all which a long and vigorous reign was peculiarly favourable. The Hindoos ſtill formed the bulk of the people; even in thoſe provinces, which, from their vicinity to the country of the conquerors, had been the moſt frequently over-run; and experience had taught the Mahomedan conquerors that the paſſive religion and temper of the Hindoos would, if left to themſelves, never diſturb the eſtabliſhed government. But the Deccan was a ſtumbling-block to the Mogul emperors, and therefore engaged the particular attention of Acbar. See DECCAN.

Acbar, who died in 1605, was ſucceeded by his ſon Selim, under the appellation of Jehanguire, who reigned about 22 years. It was in this reign, and in the year 1615, that ſir Thomas Roe was ſent as the firſt Engliſh ambaſſador to the emperor of Hindooſtan. The Portugueſe had by this time acquired conſiderable ſettlements in Bengal and Guzerat; but only thoſe in Guzerat, where they alſo poſſeſſed ſome extent of territory, attracted the notice of the court. Shah Jehan ſucceeded his father in 1628; and during this reign, *viz.* in 1633, the firſt ſerious quarrel happened between the Europeans (Portugueſe) and Moguls; and the Portugueſe were expelled from Hoogly, on the Ganges. In 1658 the civil wars commenced between the emperor and his ſons, as well as between the ſons themſelves; which terminated in the elevation of Aurungzebe, the third in deſcent, after he had depoſed his father, and murdered or expelled his brethren. For an account of his life and reign, ſee AURUNGZEBE. Aurungzebe was ſucceeded by his ſon Mauzum, who took the title of Bahader Shah, and reigned five years. Whilſt he was meditating the reduction of the Rajpoot princes of Agimere, who had formed a ſtrong confederacy, his attention was engaged by the Seiks, a new ſect of religioniſts, who appeared in arms in the Lahore province, and ravaged the whole country from thence to the banks of the Jumnah river. Theſe Seiks had ſilently eſtabliſhed themſelves along the foot of the eaſtern mountains during the reign of Shah Jehan. They differ from moſt religioniſts in that, like the Hindoos, they are perfectly tolerant in matters of faith, and require only a conformity in certain ſigns and ceremonies; but, unlike the Hindoos, they admit proſelytes. They are now become one of the moſt potent ſtates in Hindooſtan. Theſe were, after much trouble and delay, reduced by the emperor, who then took his reſidence at Lahore, where he died in 1712. A conteſt for the empire took place between his four ſons; and this ended in the eſtabliſhment of Jehaunder; but at the end of nine months he was dethroned by Ferokſere, great grandſon of Aurungzebe. It was in this reign that the Engliſh Eaſt India company obtained the famous "Firman," or grant, by which their goods of export and import were exempted from duties, or cuſtoms; and this was regarded as the company's "Commercial Charter in India," while they ſtood in need of protection from the princes of the country. In 1717 Ferokſere was depoſed, and blinded by the Seids, who aſſumed the diſpoſal of the empire and all its concerns. From this time affairs declined very rapidly; and the empire, which had acquired ſome degree of conſiſtency under the houſe of Timur, was now about to be diſmembered in a degree beyond what it had experienced, even before the era of the Mahomedan conqueſts. Mahomed Shah, grandſon of Bahader Shah, was placed on the throne by the Seids in 1718; but he contrived, by a rebellion and a battle, to get rid of the Seids. About this time, Nizam-al-Muluck, viceroy of the Deccan, was riſing into power, and meditating independency; and while he was formidable in the ſouth, the Mahrattas directed their attacks againſt the middle and northern provinces. Malwa, and the open parts of Agimere, were over-run by them; and their detachments inſulted even the capital of the empire. The weak Mahmood had, in the early part of his reign, endeavoured to conciliate them, by paying them a tribute, amounting to one-fourth of the net revenue of the invaded provinces; but this conceſſion only increaſed their inſolence, and terminated in their ſeizing on the provinces themſelves.

In 1738 the Nizam invited Nadir Shah, the uſurper of the Perſian throne, who was then engaged in the ſiege of Candahar, to invade Hindooſtan, hoping to profit by the confuſion which would thus be occaſioned. In the following year Nadir Shah entered Hindooſtan; but the ſtate of things being at this time uncertain, he offered to evacuate the empire for 50 lacks of rupees (half a million). But the intrigues of the Nizam and his party occaſioned the weak emperor to throw himſelf on the clemency of the invader, who entered Delhi, and demanded 30 millions ſterling, by way of ranſom. Tumults, maſſacres, and famine, were the reſult; 100,000 of the inhabitants were maſſacred, and 62 millions of plunder were ſaid to be collected. Nadir married his ſon to a grand-daughter of Aurungzebe, reſtored Mahomed Shah to his throne, and returned to Perſia, after obtaining the ceſſion of all the countries ſubject to Hindooſtan, lying on the W. of the Indus. The Nizam was thus left in poſſeſſion of the whole remaining power of the empire, which he ſacrificed to his own views in the Deccan, where he eſtabliſhed an independent kingdom for himſelf. The Mahratta invaſions of the Carnatic in 1740 and 1741, and the defeat and death of Doaſt Ally, nabob of Arcot, by their arms, called the Nizam home, who, on his arrival, ſettled the Carnatic, by placing Anwar O'dien, father of Mahomed Ally, in the nabobſhip of Arcot, which was then underſtood to comprehend nearly the preſent Carnatic. Bengal became independent of Delhi a little before this time (1738), under Aliverdy Cawn; and not long after it was invaded by a vaſt army of Mahrattas, both from Poonah and Berar, under the ſanction of the emperor's name, who, unable to ſatisfy their demands, ſent them to collect for themſelves the arrears of revenue ſince the defection of Aliverdy. About the ſame time, the Rohillas, a tribe from the mountains that lie between India and Perſia, erected an independent ſtate on the E. of the Ganges, and within 80 miles of Delhi. Theſe appeared very ſtrong ſymptoms of the total diſſolution of the empire. Nadir Shah died in 1747; and Abdalla, one of his generals, ſeized on the eaſtern part of Perſia, and on the bordering provinces of India, that had been ceded by Mahomed Shah to Nadir; and theſe he formed into a kingdom, known at preſent by that of Candahar, or the country of the "Abdalli," comprizing nearly the ancient empire of Ghizni. Mahomed Shah, who died this year, after a reign of 29 years, was ſucceeded by his ſon, Ahmed Shah. During his reign of ſix years, the entire diviſion of the empire took place; nothing remaining to the houſe of Timur except a ſmall territory round Delhi, together with the city itſelf (now no longer a capital), expoſed to repeated depredations, maſſacres, and famines, by the conteſts of invaders. The laſt army that might be reckoned "imperial," was defeated by the Rohillas in 1749, by which their independence was firmly eſtabliſhed in the eaſtern part of the province of Delhi. The Jates, or Jats, a Hindoo tribe under Soorage-Mull, eſtabliſhed themſelves, and founded a ſtate in the province of Agra. The Deccan and Bengal were uſurped by the Nizam and Aliverdy. Oude was ſeized on by Seifdar Jung, father to the late Sujah Dowlah, and grand-father to the ſubſequent reigning nabob of Oude, Azuph Dowlah; Allahabad by Mahomed Kooli; Malwa was divided between the Poonah Mahrattas, and ſeveral native princes, and Zemindars; Agimere reverted of courſe to its ancient lords, the Rajpoot princes; and the Mahrattas poſſeſſed, in addition to their ſhare of Malwa, the greateſt part of Guzerat, Berar, and Oriſſa, beſides their ancient domains in the Deccan. Abdalla, having eſtabliſhed his new kingdom very early in this reign, entered Lahore and Moultan (or the Panjab) with a view to the conqueſt of them. Thus the whole country of Hindooſtan proper was in commotion from one extreme to the other, and univerſal anarchy prevailed. Perhaps, in the annals of the world, it has ſeldom happened that the bonds of government were ſo ſuddenly diſſolved, over a portion of country containing at leaſt 60 millions of inhabitants. Upon the death of the Nizam in 1748, conteſts enſued for the throne of the Deccan, and occaſioned the interference of the French and Engliſh, as auxiliaries, in the wars that happened in conſequence of them, and that laſted till the year 1754. The reſult enabled the Engliſh to eſtabliſh their ſecurity and influence in the Carnatic; and the French, in addition to the ſolid advantage of getting poſſeſſion of the northern circars, valued at half a million ſterling, of annual revenue, gained the ſplendid but uncertain privilege of influencing the councils of the Nizam, by attending his perſon with their army. The Mogul was now become merely nominal, and the emperors were deprived in a great degree of their importance. Uſurpers, however, endeavoured to obtain the ſanction of their names, and the coin, throughout the whole tract, known by the name of the Mogul empire, is to this day ſtruck in the name of the nominal emperor. In 1753 the emperor Ahmed was depoſed by Gazi, after having reigned about ſix years.

In the preceding year the Mahrattas had been called in to aſſiſt in reducing the Jats, who were in poſſeſſion of Agra, and became troubleſome neighbours to the emperor; and in the preſent year the Berar Mahrattas eſtabliſhed themſelves in Oriſſa, by ceſſion from Aliverdy, nabob of Bengal, who was alſo compelled, for a ſhort time, to pay them a tribute for Bengal and Bahar, amounting to one-fourth of the clear revenue. This, together with the Mogul's former permiſſion to collect the arrears of revenue due to him, is the foundation of their claims on Bengal and Bahar; and which they have never relinquiſhed, although the times may have been unfavourable to their aſſerting them. Allumguire II. grandſon of Bahader Shah, was placed by Gazi on the nominal throne; but Abdalla, being at this time in poſſeſſion of Lahore, threatened Delhi, and in 1756 he laid the unfortunate city under heavy contributions. The emperor and his family were now reduced to the loweſt ſtate of royalty, alternately ſoliciting the aſſiſtance of Abdalla and of the Mahrattas, and as much in dread of their allies as of their enemies. In 1760 Allumguire was depoſed and murdered by Gazi. His ſon and ſucceſſor, Shah Aulum, made a fruitleſs attempt to reduce the Bengal provinces; but his expedition ended in 1761, by ſurrendering himſelf to the Britiſh, who had taken the field as allies to the nabob of Bengal. In 1759 and 1760 Hindooſtan was viſited, for the ſixth time, by Abdalla, and Delhi was again plundered and almoſt depopulated. The Mahrattas, in theſe times of confuſion and revolution, were gathering ſtrength; and, poſſeſſed of extenſive domains and vaſt armies, they projected the expulſion of Abdalla, and the reſtoration of the Hindoo government throughout the empire. Thus the principal powers of Hindooſtan were arranged into two parties, the Hindoos and Mahomedans; for the Jats joined the Mahrattas; and Sujah Dowlah, with the Rohillas, and other Mahomedan chiefs of leſs note, joined Abdalla; and a battle enſued in the plains of Carnawl and Panniput. There were ſaid to be 150,000 Mahomedans, and no leſs than 200,000 Mahrattas. Victory declared for Abdalla, after a very bloody and deſtructive battle; ſo that the Mahrattas were compelled to relinquiſh their pretenſions to univerſal empire in Hindooſtan; and from that period (1761) their power has been ſenſibly on the decline. (See MAHRATTAS.) Abdalla's influence at Delhi was now unlimited; and he determined to place Shah Aulum on the throne of his anceſtors. But he dreaded truſting himſelf in the hands of Abdalla, who ſet up Jewan Buckt, the ſon of Shah Aulum, for emperor, exacting an annual tribute; ſo that in reality Abdalla was emperor, and if he had been diſpoſed to eſtabliſh himſelf in Hindooſtan, he might probably have begun a new dynaſty of emperors in his own perſon. The territory of the young emperor, and of Nidjib Dowlah his guardian, was merely the northern part of the province of Delhi; and his father, Shah Aulum, the legal emperor, was without territory, and almoſt without friends. However, the expulſion of the nabob of Bengal, Coſſim Ally, by the Engliſh, in 1763, by drawing Sujah Dowlah into the quarrel, brought the wandering emperor again into notice; but he had more to hope from the ſucceſs of the Britiſh arms than thoſe of his patron, Sujah Dowlah; and the uninterrupted ſucceſs that attended them in 1763, 64, and 65, by the diſperſion of the armies of Coſſim Ally and of Sujah Dowlah, and by the entire conqueſt of Oude and Allahabad, left the emperor and Sujah Dowlah no hopes, but from the moderation of the victors. (See Bengal.) The private diſtreſſes of Shah Aulum, the emperor or great mogul !, were ſo preſſing, during Mr. Haſtings's laſt journey to Oude (1784) that his ſon, Jewan Buckt, came to ſolicit aſſiſtance from the Engliſh. Since the peace of 1782, Madajee Sindia, a Mahratta chief, and the poſſeſſor of the principal part of Malwa, has taken the lead at Delhi; and has reduced ſeveral places ſituated within the diſtricts formerly poſſeſſed by the Jats, and it may be concluded, that Sindia has in view to extend his conqueſts on the ſide of Agimere, and to eſtabliſh for himſelf a conſiderable ſtate or kingdom. The provinces of Agra and Delhi, and their vicinity, are in a wretched ſtate. Having been the ſeat of continual war for near 50 years; the country is almoſt depopulated, and moſt of the lands, of courſe, lie waſte; and the wretched inhabitants dare not provide more than the bare means of ſubſiſtence for fear of pillage. Nothing but the natural fertility of the ſoil, and the mildneſs of the climate, could have kept up any degree of population, and rendered the ſovereignty of it, at this day, worth contending for. In the Mogul empire, many parts of it were 1000 miles diſtant from the ſeat of government; and accordingly its hiſtory is one continued leſſon to kings, not to graſp at too much dominion; and to mankind, to circumſcribe the undertakings of their rulers.

Among the new powers that aroſe on the downfal of the Mogul empire, we ought to mention the French and Engliſh. As for the Portugueſe, their power had paſt its meridian before this period; beſides, their views being commercial, they wiſely choſe inſular ſituations, ſuch as Goa, Bombay, Salſette, Diû, &c., and never appear to have poſſeſſed any very conſiderable extent of territory, although they kept on foot a large army of Europeans. The Dutch ſyſtem was nearly the ſame; and their proſperity, in a great meaſure, grew out of the misfortunes of the Portugueſe; who, having fallen under the dominion of Spain, became obnoxious as well to the jealouſy of rivalſhip, as to the revenge of the Hollanders. The French power was of ſhort duration, but brilliant while it laſted. It began during the government of M. Dupleix at Pondicherry in 1749, and ended in 1761 by the capture of this their principal ſettlement. (See Circar.) The French appear to have been the firſt European power that trained the natives of India to regular diſcipline, as well as the firſt who ſet the example of acquiring territorial poſſeſſions, of any great extent, in India; in which they have been ſo ſucceſsfully followed by the Engliſh. Athough the Engliſh were firmly and peaceably eſtabliſhed in Bengal in 1765 (ſee Bengal); yet within two years they were engaged in a very arduous conteſt in the peninſula, with Hyder Ally, the ſovereign of Myſore, leagued with the Nizam or Soubah of the Deccan. (See Hyder Ally.) In 1767, when he had arrived at the height of his fortune, the war between him and the Engliſh broke out. Having bought off the Mahrattas, with a conſiderable ſum of money, and the reſtoration of ſome places he had taken from them, and detached the Nizam from the Engliſh, the war was proſecuted on both ſides with vigour. After ſome ſharp battles on the frontiers of the Carnatic and Myſore, a ſtrong detachment of the Britiſh army ſeized on Hyder's province of Coimbettore, a fertile diſtrict on the ſouth of Myſore, and commanding a ready way to Hyder's capital, Seringapatam. The war was continued with various ſucceſs during the years 1767, 1768, and part of 1769; when Hyder, with a ſtrong detachment of troops, chiefly horſe, eluding the Britiſh army, came within ſeven miles of Madras, and dictated a peace to the government of that place. This peace was diſreputable to the Britiſh councils only; ſince the hands of the commander in chief (general Joſeph Smith) were tied up, at the very moment, the moſt favourable for ſtriking a blow; and when Hyder, fearing the general's approach, could purchaſe his ſecurity no other way than by intimidating government into the meaſure of laying their commands on the general not to advance; by which meaſure he might poſſibly have cut Hyder and his detachment to pieces. The Nizam had, very early in the war, been detached from Hyder's alliance; chiefly by the ſtrong meaſure of ſending a detachment from Bengal into the heart of Golconda; which made him tremble for his capital, Hydrabad. The peace left matters much in the ſame ſtate as they were before the war; and whatever credit Hyder might have gained by its termination, was done away by the total defeat which he ſuffered in 1771 from the Mahratta army, within a few miles of his capital; into which he eſcaped with great difficulty, with a ſmall remnant of his army; afterwards defying the attacks of his numerous enemies, who had neither the ſkill nor the ordinary requiſites for a ſiege. His revenues and his army were improved by the few years of peace that followed. When the Mahrattas, in 1773, croſſed the Ganges to invade the Rohilla country, a brigade of the Britiſh army marched to the weſtern frontier of that country, and drove the Mahrattas acroſs the river. For this protection, the Rohilla chiefs had ſtipulated to pay Sujah Dowlah (the Britiſh army acting as his allies) 40 lacks of rupees; but when the ſervice was performed, the payment of the money was evaded. This breach of treaty led to the invaſion and conqueſt of the Rohilla country in the following year, 1774. A conſiderable tract of land in the Dooab was alſo conquered from the Jats and other adventurers, by which the boundary of Oude was advanced weſtward within 25 miles of Agra; north-weſtward, to the upper part of the navigable courſe of the Ganges; and ſouth-weſtward to the Jumnah river. In 1775, on the death of Sujah Dowlah, and the acceſſion of his ſon Azuph, a new treaty was made with the Britiſh government, by which the quantum of the ſubſidy for the uſe of the brigade was increaſed; and the province of Benares, which produced a clear revenue of 240,000*l.* per annum, was ceded to the company. The war with the Poonah Mahrattas occaſioned the march of a brigade acroſs the continent to the ſide of Bombay and Surat in 1778-9. This is ſaid to be the moſt brilliant epoch of the Britiſh military hiſtory in India. The brigade, which conſiſted of leſs than 7000 men, all native troops, commanded by European officers, marched from the banks of the Jumnah to the weſtern ſea, in ſpite of the Mahrattas, whoſe empire they traverſed almoſt the whole way. The French war breaking out at this time, and Hyder Ally expecting a communion of intereſts with the French, broke into the Carnatic, in the autumn of 1780, with 100,000 troops, foot and horſe, the beſt of their kind that had ever been diſciplined by a native of India. His ſucceſs in cutting to pieces colonel Baillie's detachment, and the conſequent retreat of the Carnatic army, occaſioned a deſpair of the Britiſh intereſts in that quarter, in the opinion of moſt people in Europe. Mr. Haſtings and ſir Eyre Coote thought otherwiſe; and there was ſent from Bengal, to the relief of the Carnatic, a brigade of about 7000 men, with ample ſupplies of money and proviſions. Until theſe troops and ſupplies arrived, the Britiſh poſſeſſed nothing more in the Carnatic than the ground occupied by their camps and fortreſſes. Under ſir Eyre Coote, Hyder was ſucceſsfully combated during two campaigns; at the end of which (October 1782) he found the poſſeſſion of his object, the Carnatic, at ſo great a diſtance, that he appeared to be ſincerely deſirous of peace. Hyder perceived the neceſſity of abandoning his ambitious projects; and he would actually have done ſo, in all probability, if he had not expected a more ſeaſonable and effectual co-operation on the part of the French, with whoſe aſſiſtance he hoped to effect our expulſion in a campaign or two. But he became more jealous of the French than of the Engliſh; and if the peace of Paris had left the Carnatic in his hands, inſtead of Mahomed Ally's, the French would have found the ill effect of his conduct reſpecting them; for he certainly never intended that they ſhould aſſume any character in it beſides that of merchants. With this diſpoſition of mind, Hyder died ſoon after, in 1783, and was ſucceeded by his ſon Tippoo, who made peace with the Engliſh in March 1784, at Mangalore. Tippoo was a prince of inferior abilities, and on a future occaſion he expiated his ill-arranged plans by his death, and the partition of his territories in 1799.

The eſtabliſhment of the Britiſh power in the Mogul empire has given a totally different aſpect to the political face of that country from that which it would have worn, if no ſuch power had ever exiſted. It is certain, that the Mahrattas, if they had been left to purſue their plans of conqueſt, would have acquired Corah and Allahabad in 1772, as well as the Rohilla country in 1773; and afterwards they might have over-run, at their leiſure, the province of Oude, and its dependencies. The Britiſh interference prevented this. On the other hand, Hyder might have kept poſſeſſion of the Carnatic. Some may be tempted to aſk, whether Hyder might not be as good a ſovereign as Mahomed Ally; or the Mahrattas, as Azuph Dowlah? Whatever may be the anſwers to theſe queſtions, ſays major Rennell, they have no reference to the Britiſh politics, which required that Hyder or Tippoo ſhould not poſſeſs the Carnatic, in addition to Myſore; and that the Mahrattas ſhould not poſſeſs Oude, or Rohilcund.

It has been ſuggeſted, that the Britiſh might have extended their poſſeſſions in Hindooſtan, *ad libitum*; lord Clive, however, thought, that the Bengal provinces and the circars, together with a moderate tract of land round Madras, and the iſland of Salſette, near Bombay, were fully equal to the meaſure of good policy, and to our powers of keeping poſſeſſion.

"The ſtate into which Hindooſtan has fallen," ſays Rennell, "ſince the downfal of the Mogul empire, is materially different from what it was before it was united under the Mahomedan conquerors. It was then parcelled out into ſeveral moderate kingdoms, which appear to have preſerved a degree of balance among themſelves; but now Hindooſtan and the Deccan may be ſaid to conſiſt of ſix (or, ſince the partition of Tippoo's territories, of five) principal ſtates, which hold, as tributaries, or feudatories, all the inferior ones; of which there are many. The reader will not be at a loſs to know, that the two Mahratta ſtates, the Nizam, Tippoo, the Seiks, and the Britiſh, are thoſe I mean; for whatever verbal diſtinctions may be made, a compulſive alliance is at leaſt a dependant, if not, in fact, a tributary ſituation." Rennell's Memoir, Ed. 3. 1793.

HINDOOSTAN, *Geography of.* This celebrated portion of Aſia, long known by the name of the empire of the Great Mogul, becauſe it was then ſubject to Mogul emperors, ſucceſſors of Timur, extends from cape Comorin on the ſouth, to the mountains which form the northern boundary of Caſhmire; that is, according to the moſt recent maps, from about the 8th to about the 35th degree of N. lat., being about 27 degrees, or nearly 1890 Britiſh miles. The northern boundary may be farther extended to the *Hindoo Koh*, and mountains running E. and W. on the N. of the province of Kuttore. In breadth this country extends from the river Araba, on the W. of the province of Sindi, to the mountains which ſeparate Bengal from Caſſay and the Birman dominions, that is, from about the 66th to the 92d degree of E. long., comprehending 26°, which, in the latitude of 25°, include 1600 Britiſh miles. On the N. the boundaries are the mountains already mentioned. On the W., towards Perſia, other ranges and deſerts form the frontier, till the river Araba terminates the ſouthern ſeparation. The other boundaries are ſupplied by the Indian ocean and bay of Bengal, where the eaſtern extremity is limited by the little river Naaf, and thoſe mountains which ſeparate the Britiſh poſſeſſions from Aracan, Caſſay, and Caſhar. The northern boundary generally conſiſts of the ſouthern ridges of the Thibetian Alps. On the N.E. of Bengal a ſimilar ridge divides Hindooſtan from the ſmall territory of Aſam, which ſeems an independent ſtate, never having formed a part of Hindooſtan, of dubious connection with Thibet, and hitherto unſubdued by the Birmans. According to the plan ſketched out and purſed by major Rennell, and judiciouſly adopted by Mr. Pinkerton, we may diſtribute the various regions of Hindooſtan into four general ſections: *viz.* the Gangetic, the Sindetic, the central, and the ſouthern.

Gangetic Hindooſtan, comprehending the countries on the Ganges, extends from the eaſtern boundaries of Bengal to the country of Sirhind, an interval of about 1000 Britiſh miles. Its greateſt breadth, from the ſources of the Chumbul, to the mountains of Sewalik, may be about 450 Britiſh miles; and the leaſt, on the W. of the province of Bengal, about 230. This ſection compriſes the provinces of Bengal, Bahar, Allahabad, Oude, and Agra; with part of Delhi and Agimere, and of Malwa in the ſouth. The Britiſh poſſeſſions in this part of Hindooſtan, including Bengal, Bahar, Benares, and ſome other diſtricts to the W., extend about 550 miles in length by 300 in breadth, forming a very powerful kingdom. The native population is computed at 10 or 11 millions of black ſubjects, excluſive of the Engliſh, whoſe number is not aſcertained. Sir William Jones, however, concluded from the actual enumeration of one province, that all the Britiſh poſſeſſions in Hindooſtan included no leſs than 30 millions of Hindoos; but major Rennell eſtimates the entire population in the time of Aurungzebe at 60 millions. The revenue of theſe Britiſh provinces is computed at 4,210,000*l.*; and deducting the expence of collection, military and civil charges, &c. being 2,510,000*l.*, the clear revenue will be 1,670,000*l.* (See BENGAL, and CALCUTTA, its chief city.) In the eaſtern part of the Britiſh poſſeſſions, the moſt conſiderable town is Dacca, which ſee. (See alſo MOORSHEDABAD and HOOGLY.) The capital of the province of Bahar is Patna; which ſee reſpectively. Benares (which ſee) is near the weſtern frontier of the Britiſh poſſeſſions. Beyond the Britiſh poſſeſſions towards the W. is Allahabad, in a province of the ſame name, ceded to the Engliſh in 1798; and to its S.W. are the diamond mines of Penna, in the ſmall province of Bundelcund, or Bundela, which ſee. The preſent capital of Oude is Lucknow; to the N.W., near the northern frontier, is Berilli; and about 50 miles W. from Lucknow is Canoge, which ſee. (See alſo AGRA and DELHI.) The fartheſt city in the ſouth of Gangetic Hindooſtan is Oujein; and the river Nerbudda may be conſidered as its moſt ſouthern limit. The ſurrounding ſtates on the E. and N. are the Roſhawn of Rennell or Aracan, Caſſay or Meckley, Aſam, Beotan, Nipal, Gorkah, Kamaoon, and Sirinagur, which ſee reſpectively.

Sindetic Hindooſtan, including the countries on the river Sindeh, or Indus, extends from the northern mountains of Caſhmire, and the Hindoo-Koh, in the north of Cabul, to the mouth of the Indus; being about 900 miles in length, and in medial breadth about 350. Beſides part of the provinces of Delhi and Agimere, it contains the extenſive province of Moultan, with Lahore, Caſhmire, Cabul, the frontier region of Candahar, and that of Sindi at the mouth of the Indus. The chief cities in this extenſive region are, Lahore, Caſhmire, Cabul, Ghizni, Candahar, Moultan, and Tatta; which ſee reſpectively.

Central Hindooſtan, comprehending the middle provinces, is chiefly bounded by Gangetic Hindooſtan on the N.; and on the W. by the ſandy deſart, and the ocean. Its ſouthern limit is the river Kiſtnah, with its tributary ſtream the Beemah; and on the E. it is waſhed by the bay of Bengal. The length from E. to W. *i. e.* from Jigat point to cape Palmiras is little leſs than 1200 miles, and the medial breadth is about 400. In this ſection are comprehended the province of Oriſſa, with part of Golconda, Berar, Dowlatabad, Candeiſh, and Guzerat, beſides other diſtricts of inferior name; and on the eaſtern ſhore are the Britiſh provinces of the Circars. The chief cities are Ahmedabad, taken by the Engliſh in 1780, and ceded to the Mahrattas in 1783, Cambay, Surat, Bombay, Burhampour, Ellickpour, Nagpour, Aurungabad, and Dowlatabad.

Southern Hindooſtan, called the Deccan, or South, and alſo Carnada or the Carnatic, is bounded by the river Kiſtnah, and its moſt northern ſubſidiary ſtreams flowing into the Beehmah, and may be conſidered as extending from the latitude of Bombay to the ſouthern point of cape Comorin, about 830 miles in length, and about 350 of medial breadth. (See Deccan.) In this diviſion may alſo be included the iſland of Ceylon, the coaſts of which are now poſſeſſed by the Engliſh, who have ſupplanted the Dutch; while the native princes retain the extenſive inland parts. In addition to the diſtrict round Madras, the Britiſh power was extended in 1792 and 1799, over wide provinces in the ſouth and weſt of Myſore; and Seringapatam, the capital, is alſo in our poſſeſſion; ſo that our territories in this portion of Hindooſtan only yield in extent and conſequence to thoſe on the Ganges. The chief cities and towns in this diviſion are Seringapatam, the moſt important; Salem and Attore on the E.; Dindigul, Coimbetore, and Palicaud, on the S.; and on the W. coaſt Paniany, Ferokabad, Calicut, now nearly deſerted, Tellicherry, and Mangalore; and on the N. Carwar, within 40 miles of the Portugueſe ſettlement of Goa, while on the S. we approach within a like diſtance of Cochin. In the Carnatic we have Madras, and not far from the weſtern frontier of our ſettlement at Madras is Arcot, eſteemed the capital of the Carnatic. To the ſouth of theſe Britiſh poſſeſſions are Tranquebar, a Daniſh ſettlement in the kingdom of Tanjore and Pondicherry, formerly the principal ſettlement of the French. On the weſtern coaſt, or that of Malabar, ſtands Cochin, which ſee. To the north of the Britiſh territories are Goa, Poona, Viſiapour, Hydrabad, Calberga, &c.

The three leading powers of Hindooſtan are the Britiſh, the Mahrattas, and the Nizam; to which may be added on the W., or Sindetic diviſion, the Seiks, and Zemaun Shah, or whatever prince holds the eaſtern diviſion of Perſia. The following table, extracted by Mr. Pinkerton, with a few alterations, from major Rennell's Memoir, will convey a ſatisfactory view of the ſtate of territory, and the ruling powers in Hindooſtan.

I. Britiſh Poſſeſſions.

1. Bengal and Bahar, with the Zemindary of Benares.
2. Northern Circars, including Guntoor.
3. Barra-Mahal, and Dindigul.
4. Jaghire in the Carnatic.
5. The Calicut, Palicaud, and Coorga countries.
6. Coimbetore, Canara, and other diſtricts acquired in 1799.

II. Britiſh Allies.

1. Azuph Dowlah, Oude.
2. Mahomed Ally, Carnatic.
3. Travancore, and Cochin.

III. Mahratta States.

Poona Mahrattas.	Tributaries.
1. Malwa.	1. Rajah of Jyenagur.
2. Candeiſh.	2. ——— Joodpour.
3. Part of Amednagur, or Dowlatabad.	3. ——— Oudipour.
4. Viſiapour.	4. ——— Narwah.
5. Part of Guzerat.	5. ——— Gohud.
6. ——— Agra.	6. Part of Bundelcund.
7. ——— Agimere.	7. Mahomed Hyat, Bopaltol.
8. Allahabad.	8. Futty Sing, Amedabad.
9. Sanore, Bancapour, Darwar, &c. ſituated in the Dooab, or country between the Kiſtnah and Toombuddra rivers.	9. Gurry Mundella, &c.
Berar Mahrattas.	Tributary.
1. Berar.	
2. Oriſſa.	Bambajee.

IV. Nizam Ali, Soubah of the Deccan.

1. Golconda.
2. Aurungabad.
3. Beder.
4. Part of Berar.
5. ——— Adoni, Rachore, and Canoul.
6. Cuddapali, Combam, and Gandicotta.
7. Part of Gooty, Adoni, and Canoul.
8. Part of the Dooab.
9. Other diſtricts acquired in 1799.

V. Seiks.

Lahore, Moultan, and the weſtern parts of Delhi.

As the other great power chiefly extends over Perſia, and may be regarded as foreign, it only remains to mention the ſmall ſtates.

1. Succeſſors of Zabeda Cawn. Schaurunpour.
2. Jats.
3. Pattan Rohillas, Furruckabad, Rohilcund.
4. Adjig Sing, Rewah, &c.
5. Bundelcund, or Bundela.
6. Little Ballogiſtan.

To which may now be added the Raja of Myſore.

Before the fall of Tippoo in 1799, the Britiſh poſſeſſions were ſuppoſed to contain 197,496 ſquare Britiſh miles, being about 60,000 more than are compriſed in the united kingdoms of Great Britain and Ireland; and the number of inhabitants was computed at 10 millions. The acquiſition in 1799 probably adds 15,000 ſquare miles, and the population ſubject to Great Britain is ſuppoſed to be 12 or 14,000,000. The net revenue exceeded 3 millions before the ceſſions by Tippoo in 1792, computed at 400,000*l.*; while thoſe in 1799 do not appear much to exceed half that ſum. For an account of the Mahrattas, Seiks, Jats, and Afghans, ſee theſe articles reſpectively.

The original population of this extenſive country may be generally conſidered as indigenous, yet it preſents conſiderable varieties; thoſe in the northern parts being fairer, and thoſe in the ſouthern almoſt or wholly black, but without the negro wool or features. The tinge, however, of the women and ſuperior claſſes is deep olive, with ſometimes a ſlight and agreeable mixture of the ruddy, and the Hindoo form and features may be ſaid to approach the Perſian or European ſtandard.

Of the mythology and religion of the Hindoos we have already given an account under the article GENTOOS. (See alſo BRACHMANS and CAST.) The governments are as various as the ſeveral ſtates. Although the Bramins are the moſt dignified caſt, the ſovereignty has been abandoned to the military caſt, and the monarch was preſumed to be proprietor of all the lands, except thoſe belonging to the church. The "Ryots" held their poſſeſſions by leaſe at a fixed rate, and conſidered them as perpetual. The "Zemindars" were, as ſome conceive, only collectors of the royal rents from the Ryots, or farmers; but, as others imagine, they were learned gentlemen, who had an hereditary right to theſe rents, upon paying a ſettled proportion to the crown. The laws are blended intimately with their religion; and an account of them may be found in the code publiſhed by Mr. Halhed, and referred to under GENTOOS.

The population of this extenſive part of Aſia conſiſts of Hindoos blended with Perſians, Greeks of Bactriana, ancient Scythians, Mahometans of various origins, Patans or Afghans from the mountains towards Perſia, Moguls, including Tartars and Mahometan tribes from the eaſt of the Caſpian, who, with the Arabs and Perſians, are generally called Moors; and it is ſuppoſed to amount to 60 millions, of which number the Britiſh poſſeſſions may probably contain a quarter. In the time of Aurungzebe the general revenues of Hindooſtan were computed at 32 millions ſterling, equal, allowing for the comparative price of the productions of the country, to 160 millions ſterling in modern England. The manners and cuſtoms of the Hindoos are very much incorporated with their religion, and are univerſally ſimilar, with ſome few exceptions in mountainous and other peculiar diſtricts. Their houſes and dreſſes are of the moſt ſimple kind, and to a Bramin nudity is no reproach. Their amuſements conſiſt of religious proceſſions, and though dancing girls are numerous, theatrical exhibitions are leſs common than in countries farther to the eaſt. The general ancient language of Hindooſtan is believed to have been the *Sanſcrit;* which ſee: but of this there are various dialects in different provinces. Of their literature we have had many confuſed and contradictory reports; but their moſt important books are the Vedas. (See BRACHMANS.) Dr. Robertſon alleges ſeveral conſiderations in proof of the ancient and high civilization of the Hindoos; but againſt his arguments to this purpoſe others have advanced many objections. (See CAST.) The arguments of M. Bailly and others for the antiquity of the Hindoo aſtronomy have been attacked with great force by Mr. Bentley, in a learned diſſertation publiſhed in the ſixth volume of the Aſiatic Reſearches, 1799: and the reſult appears to be, that the ſyſtem, ſo highly extolled and traced to remote antiquity, cannot be of a greater age than 731 years; or that it was compoſed about A. D. 1068.

The chief univerſity in the north is that of Benares; and in the Deccan, the academy of Triciur, on the Malabar coaſt, is alſo in great repute: and at Cangiburam, in Carnate, we are told, there is ſtill a celebrated Brahman ſchool, which, according to the teſtimony of Ptolemy, exiſted in the firſt century of the Chriſtian era, and its members, it is ſaid, are equal in celebrity to the Brahmans of Benares. The manufactures of Hindooſtan have been celebrated from a remote antiquity, particularly thoſe of muſlins and other cotton fabrics. Piece goods, as we call them, are mentioned by the authors of the Periplus, and other ancient writers, who commend both the manufacture and the beautiful colours of the dyes. In the time of Strabo, the Hindoos were famous for elegant works in metals and ivory. Hindooſtan, however, is not celebrated at this day for any manufacture, except thoſe of muſlins and calicoes; the other exports conſiſting of diamonds, raw ſilks, with a few wrought ſilks, ſpices, drugs, &c.

Painting and ſculpture are in their infancy; and yet the temples are majeſtic and ſolemn. Hindooſtan has, in all ages, been chiefly famed for its native products; its diamonds, and ſome other precious ſtones, its ſpices, aromatics, and drugs: rice alſo, ſugar, and many articles of luxury, are products of Hindooſtan.

The climate and ſeaſons are conſiderably diverſified by difference of latitude and local ſituation; nevertheleſs, through the wide regions of Hindooſtan there is ſome ſimilarity of climate. (See BENGAL.) Although in Thibet the winter nearly correſponds with that of Switzerland, and other parts of Europe, in the whole extent of Hindooſtan, except in Caſhmire, there can hardly be ſaid to be a veſtige of winter, except the thick fogs of our November; and exceſſive rains, or exceſſive heats, form the chief varieties of the year. The aſpect of the country is very much diverſified; but there are no mountains of any very great height; the Gauts (which ſee) not being eſtimated at above 3000 feet. The vaſt extent of Hindooſtan conſiſts chiefly of large plains, fertilized by numerous rivers and ſtreams, and interſperſed with a few ranges of hills. The periodical rains and intenſe heats produce a luxuriance of vegetation, almoſt unknown to any other country in the globe; and the variety and richneſs of the vegetable creation delight the eye of every ſpectator. The ſoil in ſome places is ſo excellent, that it conſiſts of black vegetable mould to the depth of ſix feet. Rice is the chief grain, which is induſtriouſly watered on the dry ſandy lands of the coaſt of Coromandel. Maize and the ſugar-canes and cotton are alſo much cultivated. But the implements of huſbandry are in general ſo imperfect, that they owe to the fertility of the land what they want either in ſkill or diligence of agricultural operations.

The two principal rivers of Hindooſtan are the Ganges and Burrampooter, which ſee; the chief tributary ſtreams of the Ganges are the Gagra or Sarjoo, the Jumnah, which receives the Chumbul, Betwa, and ſeveral others, and the Soan. The Indus, or Sindeh, with its confluent ſtreams, is alſo a principal object. Its tributary ſtreams are very numerous; ſee SINDEH. The chief rivers of the central part of Hindooſtan are the Pudda, Nerbudda, and Taptee, on the W.; the Subanreeka, the Godaveri, &c. In the ſouthern part of Hindooſtan are the Kiſtnah, Pennar, Paliar, and Caveri. This country has few lakes; thoſe of Colair, Chilka, Pulicat are mentioned by Rennell. The mountains, diſcriminated by their modern names, are the Tipera, Garro, Himmaleh, Hindoo-Koh, Gauts, &c. Hindooſtan abounds with foreſts, ſome of which are near the mouths of the Ganges, &c. others in the rude unexplored regions on the W. of the Circars. On the eaſt of the Indus is a ſandy deſert, between 4 and 500 miles long, and from 60 to 150 miles broad; it is ſtyled that of Agimere, and was known to Herodotus. The botanical productions of this fertile country are too numerous and various to be recited. Its cattle are frequently of a large ſize, with a hunch on the ſhoulders; and its ſheep are covered with hair inſtead of wool, except in the moſt northern parts. Antelopes, camels, elephants, apes and monkies, dogs, wild boars, bears, wolves, foxes, jackals, hyænas, leopards, panthers, lynxes, and many other quadrupeds are found in this country. It would be endleſs o enumerate the birds, ſiſhes, and inſects that abound in Hindooſtan. We ſhall conclude this article with mentioning ſome of its moſt celebrated mines. Thoſe of the diamond are near Viſiapour and Golconda, at Raolconda, in a diſtrict on the river Mahanada, S. of Sumboulpour, Gandicotta on the river Pennar, and Penna in the territory of Bundelcund, about 60 miles S. of the river Jumnah, which flows into the Ganges. (See DIAMOND.) Robertſon's India. Raynal's Indies, vol. i. Rennell's Memoir, paſſim. Pinkerton's Geography, vol. ii.

HINDOOSTANEE, the vernacular language of the Hindoos. It is alſo frequently denominated *Hindu*, *Oordoo*, and *Rekhtu*. It is compounded of Shanſcrit, Perſian, and Arabic. The firſt of theſe was the great original language of India, and to it may be traced ſuch terms in the provincial dialects as are of truly Indian original: and ſuch words as bear no relation to the Shanſcrit roots are either Perſian or Arabic.

The Perſian was carried into India by the Mogul conquerors, and being the language of the court, naturally gained a footing in the law and in the revenues. It has alſo for ſome centuries been the common medium of negotiation between the ſeveral ſtates of Hindooſtan; and from thence became an almoſt indiſpenſible qualification for thoſe who were engaged in the management of Indian affairs. The Perſian is ſtill uſed by all the Mogul officers of government, in their ſeveral departments of accounts and correſpondence. Thus the Hindooſtanee received a great influx of Perſian terms, and many peculiarities of the Perſian idiom. The original language of the Hindoos, from a ſimilar cauſe, became debaſed by a copious mixture with Arabic. When the Mahometan invaders firſt ſettled in India, from the neceſſity of having ſome medium of communication with the natives, whom they had conquered, they applied themſelves to the ſtudy of the Hindooſtanee dialect. The knowledge of the Shanſcrit was impracticable, from the invincible averſion of the Gentoos to teach to foreigners, and to conquerors, the uſe of their own tongue. The latter, therefore, had no reſource but to introduce, as far as they could, their own language. New adventurers, continually arriving, kept up a conſtant influx of exotic words, and the heterogeneous maſs gradually increaſed its ſtock, as conqueſt or policy extended the boundaries of its circulation. But theſe alterations affected words only. The grammatical principles of the original Hindooſtanee, and the ancient forms of conjugation and inflexion remained the ſame; and whilſt the primitive ſubſtantives were excluded, or exchanged, the verbs maintained both their inflexions and their regimen. The Shanſcrit, indeed, has a dual number, both to nouns and verbs, the Hindooſtanee to neither. Verbs in Shanſcrit have the ſame form for both the maſculine and feminine genders. The Hindooſtanee verbs are diſtinguiſhed by different terminations for the different ſexes, like thoſe of the Arabic. Theſe are the capital outlines of diſſimilarity between the Shanſcrit and the Hindooſtanee; but in the original appropriation of particular words to particular ſenſes, in the idiomatic turns of expreſſion, and complexion of ſpeech, we may obſerve the ſtrongeſt family likeneſs. The characters alſo, peculiar to the Hindooſtanee, are exactly the ſame with thoſe of the Shanſcrit, but of a ruder ſhape, yet ſtill exhibiting a more accurate reſemblance than is found in many of the Greek letters in inſcriptions of different eras.

From the above ſtatement it is obvious, that the primitive Hindooſtanee tongue has by no means preſerved its purity or its univerſality to the preſent age: for the modern inhabitants of India vary almoſt as much in language as in religion: and at preſent thoſe perſons are thought to ſpeak this compound idiom with the moſt elegance, who mix with rare Indian verbs the greateſt number of Perſian and Arabic nouns. Such of the Hindoos as have been connected with the Muſſulman courts, or admitted to any offices under that government, have generally complimented their maſters by a compliance with theſe literary innovations. But the Bramins, and all other well-educated Gentoos, whoſe ambition has not overpowered their principles, ſtill adhere with a certain conſcientious tenacity to their primeval tongue.

As the intercourſe and communication of the Muſſulmen with the natives of India was greater or leſs, according to certain circumſtances and ſituation, the Hindooſtanee naturally varied conſiderably with reſpect to the prevalence of one or other of the three great languages compoſing it. This circumſtance, ſays Mr. Bailey in his Collegiate *Theſis* on the importance of this language, will ſanction a diviſion of it into three diſtinct dialects, namely, the priſtine or country; the middle or familiar; and the learned or court dialect; each of which are reſpectively uſeful in different diſtricts. In the firſt or priſtine dialect, there is a ſmaller admixture of foreign words. Hence this is more nearly related to the original dialect of the country. In the ſecond, or familiar dialect, the number of foreign words bears nearly an equal proportion to the original ones. In the third, or court dialect, Arabic and Perſian words are by far the moſt numerous.

In recommending the ſtudy of this language, the abovementioned author affirms that to the merchant, the traveller, the civil and military officer, the philoſopher and phyſician, in ſhort, to every one who carries on concerns of any moment in India, the Hindooſtanee language is more generally neceſſary and advantageous than any other. For this reaſon it is of late become an object of indiſpenſible attainment to all thoſe young gentlemen who are deſtined to engage in Indian affairs. In the whole of the vaſt country of Hindooſtan, ſcarcely any Muſſulman will be found who does not underſtand and ſpeak the Hindooſtanee. Every Hindoo alſo, of any diſtinction, or who has the leaſt connection either with the Muſſulmen or the Britiſh government, is acquainted more or leſs with this language. It is moreover the general medium by which foreigners, ſuch as the Portugueſe, Dutch, Danes, French, Arabs, Turks, Americans, Perſians, Moguls, and Chineſe communicate their ideas to each other. In almoſt, too, all the armies of India this appears to be the language univerſally uſed: though many of the individuals compoſing them muſt be better acquainted with the dialects peculiar to their reſpective diſtricts. Finally, from Cape Comorin to Cabul, a country about 2000 miles in length, and 1400 in breadth within the Ganges, few perſons will be found in any large villages or towns, which have been conquered or much frequented by Muſſulmen, who are not ſufficiently converſant in the Hindooſtanee, and in many places beyond the Ganges this language is current and familiar.

The dialect called the *Moors*, is that mixed ſpecies of Hindooſtanee which owed its exiſtence to the Mahometan conqueſts. In this idiom ſeveral elegant poems and tales have been compoſed by learned Perſian and Mogul authors, and are ſtill extant in the libraries of the curious. Theſe are always written in the Perſian hand, which is by no means calculated for expreſſing the ſound either of the Hindooſtanee vowels or naſal conſonants. The Mahometans of the lower rank have a few books on religious ſubjects in this language and in the *Naagore* characters; which are alſo uſed by ſome of them in their petty accounts. Europeans, on their arrival in India, reduced to a neceſſary intercourſe with Mahometan ſervants or Sepoys, habitually acquire from them this idiom in that imperfect and confuſed ſtate, which is the conſequence of the menial condition of their inſtructors. Yet this curious ſyſtem of ſtudy hath produced more than one attempt to a grammar and vocabulary.

Theſe attempts are unworthy of notice; but the labours of Dr. Gilchriſt deſerve particular attention. His Engliſh and Hindooſtanee dictionary, which was intended to be followed by another part in Hindooſtanee and Engliſh, is a highly valued production, and his grammar, as containing a copious detail of the language with numerous ſpecimens of Indian poetry, is a performance not leſs valuable and uſeful to the oriental ſtudent, though it cannot boaſt the ſimplicity, the taſte, the philoſophical acuteneſs, and the extenſive acquaintance with the claſſical languages which diſtinguiſh the Perſian grammar of ſir W. Jones, or Mr. Halhed's grammar of the Bengaleſe. But Dr. Gilchriſt's chief merits conſiſt in the attempt which he has made to teach the Hindooſtanee language in European characters. To effect this purpoſe with ſucceſs, required great ſkill and diligence, as many European letters correſpond as little in ſound, as they do in form, to thoſe of Aſia. There are two general modes, (ſays ſir W. Jones, in his Diſſertation on the Orthography of Aſiatic Words,) of exhibiting Aſiatic words in our own letters; they are founded on principles nearly oppoſite, but each of them has its advantages, and each has been recommended by reſpectable authorities. The firſt profeſſes to regard chiefly the pronunciation of the words intended to be expreſſed, and this method, as far as it can be purſued, is unqueſtionably uſeful; but new ſounds are very inadequately preſented to a ſenſe not formed to receive them; and the reader muſt, in the end, be left to pronounce many letters and ſyllables precariouſly; beſides that, by this mode of orthography all grammatical analogy is deſtroyed, ſimple ſounds are repreſented by double characters, vowels of one denomination ſtand for thoſe of another; and poſſibly with all our labour we perpetuate a provincial or inelegant pronunciation. The ſecond ſyſtem of Aſiatic orthography conſiſts in ſcrupulouſly rendering letter for letter without any particular care to preſerve the pronunciation. The firſt of theſe methods had an advocate in major Davy, an elegant Perſian ſcholar, and a member of the Aſiatic ſociety; the ſecond found two able ſupporters in Mr. Halhed and Dr. Wilkins, to whom ſir W. Jones bears the honourable teſtimony of having done more towards promoting Indian literature, than Europe or India can ever ſufficiently acknowledge. The former juſtly remarks that the two greateſt defects in the orthography of any language, are the application of the ſame letter to ſeveral different ſounds, and of different letters to the ſame ſound, and theſe defects he truly pronounces to be ſo common in Engliſh that he was exceedingly embarraſſed in the choice of letters to expreſs the ſound of the Bengal vowels, and was at laſt by no means ſatisfied with his own ſelection; Dr. Gilchriſt has adopted neither of the above modes, but embraced a ſcheme which affords the advantages of both, without the inconveniences peculiar to either. His plan is to define the ſound of the European letters, and then to uſe them in every word as repreſentatives of the Hindooſtanee elements, without ever the ſlighteſt variation. The Indian letters ſeldom experience any change of pronunciation, and it was only neceſſary to adjuſt their ſound to our characters, in order to expreſs them with correſponding uniformity. By this plan he has paid due attention to the pronunciation of each word, and of its elements. His ſyſtem is peculiar to himſelf, and is likely to be rejected by thoſe who cannot pay to it the time and attention neceſſary to perceive its excellence, and to reap its advantages. The ſcholar who can make this ſacrifice, will readily acknowledge the uſefulneſs of Dr. Gilchriſt's ſyſtem, though he cannot fail to lament the pedantry and want of ſimplicity which disfigures his works.

HINDOWN, in *Geography*, a town of Hindooſtan, in the Subah of Agra; 25 miles N. of Kerowly. This has been a large city, and contains extenſive buildings, but, in conſequence of the depredations of the Mahrattas, is now thinly inhabited.

HINE, or Hind, in the *Saxon Language*, ſignifies a ſervant, or one of the family; but it is now taken in a more reſtrictive ſenſe, for a ſervant at huſbandry; and the maſter hine is he that overſees the reſt.

HING, in *Geography*, a town of China, of the ſecond rank, in the province of Kiang-nan. N. lat. 32° 35′. E. long. 305 26′.

HINGES, in *Building*, thoſe neceſſary iron ligaments, by means whereof doors, lids, folds of tables, &c. make their motion, whether of opening, ſhutting, or folding.

The ſpecies of hinges are many, *viz.* bed, box, butts, caſement; caſting, cheſt, coach, deſk, dove-tails, eſſes, folding, garnets, weighty, ſide, ſide with riſing joints, ſide with ſquares, ſcrew, ſcuttle, ſhutter trunk of ſundry ſorts, and hook and eye hinges.

HINGHAM, in *Geography*, is a ſmall town and pariſh in the hundred of Forchoe, in the county of Norfolk, England, 96 miles diſtant from London, and contains 179 houſes, and 1203 inhabitants. It was anciently part of the poſſeſſions of the Marſhals, afterwards earls of Pembroke; from whom it came to the Morleys, and thence to the Wodehouſes, in which family it is at preſent veſted. The church, which is a handſome ſtructure, with a large and lofty tower, was rebuilt by Remigius de Hetherſete, the rector, aided by the munificence of the patron, John le Marſhall, in the reign of Edward III. Several chapels and numerous images decorated the interior prior to the Reformation. In the church were held ſeven guilds, each having a ſtipendiary chaplain ſerving at the reſpective altars, conſtituting a choir. On the north ſide of the chancel is a noble canopied monument, reaching from the floor to the roof, richly decorated with ſtone imagery and tracery: many of the braſſes are gone, but from the arms remaining it appears to have been erected to the memory of Thomas lord Morley, who died in the reign of Henry VI. Hingham has a weekly market on Saturdays, and three annual fairs. Blomefield's Hiſtory and Antiquities of Norfolk.

Hingham, a poſt-town of America, in Suffolk county, Maſſachuſetts, ſituated on a ſmall bay, S. from Boſton bay. It contains a number of houſes, compactly built, two congregational churches, and a well endowed ſchool. It is 19 miles S.E. of Boſton. The townſhip is about four miles ſquare, including two pariſhes, incorporated in 1635, and containing 2112 inhabitants.

HING-HOA, a city of China, of the firſt claſs, in the province of Fo-kien, near the ſea-coaſt. It is adorned with ſeveral triumphal arches and majeſtic public buildings. The adjacent country furniſhes rice and ſilk in abundance. N. lat. 25° 28′. E. long. 118° 56′.

HING-NGHAN, a city of China, of the ſecond rank, in Chen-ſi, on the river Han. N. lat. 32° 34′. E. long. 108° 54′.

HINGWANG, in *Natural Hiſtory*, a name given by the people of the Eaſt Indies to a ſpecies of red arſenic, which they uſe in painting and in medicine. They find it in and about the copper mines. It is calcined ſeveral times, in order to fit it for internal uſe. In painting, it makes a very fine orange-colour; but when mixed with ceruſs, it makes a lemon-colour, and any other ſhade of yellow.

It ſeems to contain ſome portion of ſilver, and ſome cinnabar.

HINIGAN, in *Geography*, a town of the Arabian Irak; 100 miles W. of Baſlora.

HINISBURG, a poſt-town of America, in Chittenden county, Vermont, E. of and joining Charlotte on lake Champlain, containing 933 inhabitants.

HINKA, a lake of Chineſe Tartary, about 108 miles in circumference. N. lat. 44° 35′. E. long. 132° 29′.

HINKAN, a chain of mountains of Chineſe Tartary, which reach from N. lat. 55° to 53° and from E. long. 134° to 137°.

HINLOPEN Straits, a channel of the North ſea, between North-Eaſtland and Spitzbergen.

HINNERJOKI, a town of Sweden, in the government of Abo; 30 miles S. of Biorneborg.

HINNULUS, in *Zoology*, a hind; the young of the deer or goat kind.

Hinnulus. See Moschus *Pygmæus*.

HINNY, a ſpurious or hybrid quadruped, the produce of the horſe with the female aſs. Its ſize is leſs than that of the horſe, the ears and mane the ſame as in that animal; the colour is redder, and the tail like that of the female parent.

HINOJARES, in *Geography*, a town of Spain, in the province of Jaen; 15 miles S.E. of Ubeda.

HINOJOSA, a town of Spain, in the province of Leon; 25 miles N.N.W. of Civdad Rodrigo.—Alſo, a town of Spain, in the province of Eſtremadura; 16 miles N. of Llerena.—Alſo, a town of Spain, in New Caſtile; 10 miles N. of Molina.

HINOJOSAS, Las, a town of Spain, in New Caſtile; 36 miles S. of Hueta.

HINSDALE, a townſhip of America, in Cheſhire county, New Hampſhire, on the eaſt bank of Connecticut river, oppoſite to Vernon in Vermont, incorporated in 1753, and containing 634 inhabitants; 38 miles above Northampton.

HINZUAN. See Joanna.

HIO, a town of Sweden, in Weſt Gothland, ſeated on the Wetter lake, with a good ſalmon fiſhery; 80 miles N.E. of Gotheborg. N. lat. 58° 20′. E. long. 13° 58′.

HIORRING, a town of Denmark, in N. Jutland, and dioceſe of Aalberg, formerly a large city and the ſee of a biſhop, with three churches; but in 1693 almoſt deſtroyed by fire, ſo that the biſhopric was removed to Aalberg by Frederic II.; 27 miles N.N.W. of Aalberg. N. lat. 57° 27′. E. long. 10°.

HIORTED, a town of Sweden, in the province of Smaland; 60 miles N. of Calmar.

HIORTOE, a ſmall iſland of Denmark, near the W. coaſt of Taaſinge. N. lat. 54° 53′. E. long. 10° 30′.

HIP, in *Architecture*, a piece of timber placed between every two adjacent inclined ſides of a hipped-roof, for the purpoſe of fixing the jack rafters. For the manner of finding the length and backing of the hips, ſee Hipped *Roof*.

Hip, a particular part of an animal. See Haunch.

Hip, in the *Materia Medica*, the fruit of the cynoſbatus ſhrub, wild briar, hip-tree, or dog-roſe. See Rosa *Canina*.

Hips are agreeably dulco-acid, and ſtand recommended as cooling reſtringents, in bilious fluxes, ſharpneſs of urine, and hot indiſpoſitions of the ſtomach; but they are very little uſed in the ſhops, except in the *conſerve*, which ſee.

Hip-*gout*, in *Medicine*. See Sciatica.

Hip-*joint*, *Diſeaſe of*. What is uſually underſtood by the diſeaſe of the hip-joint, in *Surgery*, is a diſtemper very analogous to the white ſwelling of other articulations. By ſeveral writers it is treated of under the name of *iſchias*, which term, however, has been moſtly applied to rheumatic affections of the hip. Like the white ſwelling, the diſeaſe of the hip-joint probably has its varieties, ſome of which are undoubtedly connected with ſcrofula, while others cannot be ſuſpected of having any concern with a ſtrumous habit. Mr. Crowther obſerves, that no caſe has hitherto occurred to him, in which the patient was not of the latter kind of conſtitution, although, if we underſtand him rightly, he adds an exception in regard to ſome of the caſes, which are produced by accidents. (On White Swelling, &c. p. 257, 258, edit. 2.) We believe, that, in a given number of caſes, there are more diſeaſed hips, quite independent of ſcrofula, than there are white ſwellings of other joints. It is univerſally acknowledged, by all experienced ſurgeons, that young ſubjects are moſt liable to ſcrofulous diſeaſes, and, of courſe, to that affection of the joints, which is commonly conſidered to be connected with a ſtrumous conſtitution. If a perſon live to the age of five and twenty, perfectly free from all ſcrofulous ſymptoms, the hazard of his ever becoming afterwards afflicted with a true ſcrofulous complaint may be regarded as almoſt entirely paſt. Hence, all morbid affections of the joints, firſt occurring after this period of life, and under ſuch circumſtances, cannot be reaſonably conſidered as having any connection with ſcrofula.

The generality of ſurgical authors ſeem to agree, that the diſeaſe of the hip-joint is moſt commonly met with in children under the age of fourteen, and, in this reſpect, it is exceedingly analogous to the true white ſwelling. But no age is exempt from the malady: ſo that, though children form a large proportion of thoſe ſubjects who are afflicted, yet the number of adults, and even of old perſons, is much more conſiderable, in a given number of theſe caſes, than we find to occur in the ſame number of caſes, in which the knee is diſeaſed. Such is our reaſon for believing, that there are more hip caſes unconnected with ſcrofula, than there are examples of white ſwellings being ſimilarly circumſtanced. The obſervation is of courſe only applied to a definite number of caſes of each diſeaſe; for the much more frequent occurrence of morbid knees, ankles, wriſts, and elbows, would deſtroy the accuracy of the remark, if taken in a general ſenſe.

The approach of the hip diſeaſe is far more inſidious, than that of a white ſwelling. The latter is generally preceded by ſevere pains; while the only fore-runner of the former is frequently a ſlight weakneſs and limping of the affected limb. This ſtate is too often overlooked, and, when noticed by men little verſed in the profeſſion, is commonly treated on principles the moſt repugnant to ſurgical ſcience. Embrocations are generally preſcribed, without any injunction to keep the limb in a quiet ſtate. The application is alſo oftentimes made to the knee, or other part of the extremity; for as there is frequently an uneaſineſs about that joint, when the hip is affected, and as no pain whatever is ſometimes mentioned, as occurring in the latter ſituation, till a more advanced period of the malady, it is not uncommon to ſee careleſs practitioners directing their remedies to ſome ſituation very different from that of the diſeaſe. This combination of neglect and ignorance is the more to be lamented, inaſmuch as the incipient period of the complaint is the only one in which a favourable prognoſis can ever be made, mere reſt, and repeated topical bleeding, having now more effect, in the courſe of a fortnight, than large painful iſſues will afterwards generally have in the long ſpace of a twelvemonth.

The firſt diagnoſtic ſymptoms of diſeaſe in the hip-joint, if we merely look for them in the ſituation of that articulation, are not particularly conſpicuous. It is true, that a fixed pain behind the trochanter major, in ſome inſtances, very ſoon excites the attention of the ſurgeon to the ſeat of the morbid affection. But mere pain in a joint, quite free from viſible enlargement, and external change of colour, is generally diſregarded as a complaint of no importance in young ſubjects, and as a mere rheumatic, or gouty affection in adults. Even when the pain begins to be ſevere, it is commonly not confined to the ſeat of the diſeaſe, but ſhoots downward, in the courſe of the vaſtus externus muſcle, to the knee, and along the outer part of the fibula to the malleolus externus. The patient often refers moſt of his painful ſenſations to the groin. In ſhort, there is no particular ſymptom occurring in the preciſe ſituation of the morbid affection, ſo as to form an infallible pathognomonic mark of its exiſtence. But ſtill the characters of the diſeaſe are very ſtrong, when examined by a ſurgeon, who has paid attention to the ſubject.

Almoſt as early as the leaſt limping can be perceived, ſome diminution in the circumference of the leg and thigh has actually taken place, as may be eaſily diſcovered by a careful meaſurement.

The hip-joint is deeply ſituated, ſo that its accidents and diſeaſes cannot be examined as readily as thoſe of many other articulations. The generality of ſurgeons little think, that the proper place for preſſing on the hip-joint, with a view of aſcertaining the preſence of diſeaſe, is a little on the outſide of the femoral artery, ſoon after it has deſcended below the brim of the pelvis. At this ſpot, the ſurgeon may apply preſſure to the front of this large articulation, and if it be diſeaſed, conſiderable pain will be the conſequence of the experiment.

The limping gait denotes, that ſomething is wrong in the limb, and if this ſymptom cannot be attributed to an affection of the vertebræ, or a recent accident; and if it be conjoined with the above-mentioned emaciation of the affected member, an exaſperation of pain on preſſing the front of the acetabulum; the evidence of diſeaſe in the hip becomes more and more convincing. It has appeared to us, that the weakneſs of the lower extremities from diſeaſed vertebræ always affects both limbs at once, and is unattended with pain about the knee, circumſtances completely deſcriminating this complaint from the feebleneſs of the limb, ariſing from the diſtempered ſtate of the hip-joint.

The marks of diſcrimination, juſt pointed out, between two diſeaſes of ſo different a nature, may appear to ſome perſons quite ſuperfluous. We entertain an oppoſite opinion. The diſeaſe of the vertebræ, and the affection of the hip, are both in the incipient ſtate often attended with little elſe than a certain weakneſs in walking, at leaſt with no other ſymptom, which would ſtrike an uninformed perſon. Almoſt every ſurgeon muſt have ſeen many caſes in which the vertebræ are diſeaſed, and attended with more or leſs lameneſs, without there being any preternatural projection of the ſpinous proceſſes whatſoever. Such projection, indeed, from the nature of the changes going on in the bones, can never happen, till the diſeaſe has made conſiderable advance. Beſides, it is a well known fact, that ſome practitioners are either ſo negligent, or ignorant, that they never advert at all to the ſtate of the back, as the cauſe of lameneſs. How many caſes have we ſeen, in which children's legs have been rubbed with liniments, while their backs were never examined, nor ſuſpected, as being the ſeat of the primary diſeaſe, to which the paralytic weakneſs of the limbs was entirely owing. If Mr. Crowther's aſſertion be true, that in caſes of diſeaſed vertebræ, one limb is little affected with lameneſs, while the power of the other is much impaired, the neceſſity for every ſign of diſcrimination will be ſtill greater, becauſe, when the ſpinous proceſſes do not project, as is often the caſe at firſt, a ſerious lameneſs on one ſide will be the only one particular complaint, both in diſeaſe of the ſpine and of the hip. The obſervations, however, which we have made, by no means juſtify the concluſion, that either in the early or advanced period of the diſtemper of the vertebræ, one leg is always, or even generally, affected with little lameneſs in compariſon with the great weakneſs of the other. But whether there are examples, in which one limb ſuffers ſo much more than the other or not, has nothing to do with the fact advanced, that in caſes of diſeaſed vertebræ, both limbs are affected with weakneſs. The projection of the ſpinous proceſſes is, in the earlier periods of the diſorder, far leſs invariable.

Another remarkable ſymptom of the diſeaſe of the hip, in its early ſtage, is an elongation of the limb, a circumſtance, which is quite manifeſt, on comparing the condyles of the os femoris, the patella, the trochanter major, and the malleolus internus of the diſeaſed limb, with the ſame parts of the ſound one.

Until lately, no ſatisfactory explanation had been given, by ſurgical writers, of the manner in which the lengthened ſtate of the limb was produced in the early ſtage of the hip diſeaſe. "The ancients, and, indeed, many practitioners, even of modern times, have aſſigned as cauſes of the increaſed length of the limb, a ſuppoſed relaxation of the orbicular ligament, or a diſtention of the articular cavity by fluid effuſed into the capſule. Such are the notions brought forward by Galen and Fabricius, to illuſtrate the meaning of the two aphoriſms of Hippocrates, concerning the nature of this diſeaſe." Sæpe in articulis humor pituitoſus acervatur, quem myxam appellat, (Hippocrates,) a quo madefacta articulationis ligamenta, laxiora redduntur: atque ideo facile a cavitate articulus excidit, et rurſus non cum difficultate incidit. Galen. in Aphor. Hippocr. Comm. 6. See Crowther on White Swelling, &c. p. 259. edit. 2.

We ſhall paſs over the erroneous opinions, that the limb is lengthened by a diſtention and relaxation of the orbicular ligament, or by a ſwollen ſtate of the head of the thigh-bone, and a thickening of the acetabulum, or in conſequence of a deſtruction of the articular cartilages, and of the ligament completing the lower and inner margin of the acetabulum. In ſhort, nothing can be more certain, than that while the elongation of the limb laſts, the head of the bone muſt be ſituated in the acetabulum, or elſe the muſcles would draw the bone upwards, and ſhorten the member, as we find actually occurs as ſoon as the upper and poſterior part of the acetabulum, and the ligamentum teres are ſo deſtroyed, that they make no reſiſtance to this kind of diſlocation.

If then the head of the bone does not quit its ſituation, the lengthened ſtate of the limb can depend upon nothing leſs, than an alteration in the poſition of the pelvis. That the pelvis does undergo a change of its poſture is now perfectly aſcertained. The publication in which this fact was firſt noticed, we believe, is Dr. Falconer's pamphlet on iſchias. "The tubercle, or lower part of the iſchium may, in many inſtances, but not always, be diſcovered by feeling it behind to be lower on the affected ſide than the other. A man, now in the hoſpital, is a remarkable inſtance of the difference between the height of the bones on each ſide; and a pelvis of a perſon who died at the ſame place, and was preſerved there many years, ſhewed it ſtill more ſtrongly." It appears, from ſome remarks in Mr. Crowther's work on the white ſwelling, that Mr. John Hunter uſed to attribute the lengthening of the limb to the ſituation of the pelvis. Mr. Crowther and Mr. Lawrence inſtituted together an examination of this point, upon two children with diſeaſed hips, and they aſcertained, that when the patients were laid on the table, with the whole body in a ſtraight line, the anterior ſuperior ſpinous proceſs of the ilium on the affected ſide was lower than that of the ſound one, juſt in proportion to the difference in the length of the two limbs; this was about a quarter of an inch in one patient, and a full inch in the other. A ſimilar obliquity of the pelvis was equally manifeſt from behind, when the patients were placed on the abdomen, with the precaution of laying the body in a ſtraight line. It was impoſſible to place the pelvis in its natural horizontal poſition, without bringing the body into a curved line, and when this was done, the lower extremities, inſtead of falling ſtraight under the body, deviated from the perpendicular towards the diſeaſed ſide. A ſtraight line drawn along the ſpinous proceſſes of the ſacrum, and continued downwards, did not fall between the lower limbs, as it would in a pelvis, poſſeſſing its natural poſition, but, on the contrary, extended to the heel of the ſound limb. Mr. Crowther thinks, that in theſe caſes, the obliquity of the pelvis can be aſcribed to no other cauſe, than that of the patient's endeavouring to throw the weight of the body, as much as poſſible, on the ſound hip. The pain, and the general weakneſs of the affected limb, induce a conſtant effort of this kind. Hence children are obſerved bending the knee and hip, and hopping about on the healthy limb. The pelvis naturally ſinks on the diſeaſed ſide, and this deviation, which would affect the centre of gravity of the whole body, is counterbalanced by a bend of the upper parts of the trunk towards the ſound ſide. Accordingly, both the patients under Mr. Crowther were noticed to incline their heads towards the ſhoulder of the ſound ſide of the body. On White Swelling, &c., p. 265—268, edit. 2.

Another remarkable ſymptom which attends the diſeaſe of the hip-joint, is the alteration in the natural fulneſs and convexity of the nates, that part appearing flattened which is uſually moſt prominent. The glutæus magnus becomes emaciated, and its edge no longer forms ſo bold a line, as it naturally does, at the upper and back part of the thigh, in the ſound ſtate of the limb. This is one very ſtrong feature of the early ſtate of the diſeaſe, and has been accurately repreſented in one of the plates of the late Mr. Ford's book on the preſent ſubject.

Though there may be more pain about the knee than the hip at ſome periods of the malady in its incipient ſtate, the former joint may be bent and extended without any increaſe of uneaſineſs; but the thigh-bone cannot be moved without a vaſt increaſe of the patient's ſufferings.

Patients with diſeaſed hips ſoon get into the habit of bearing the weight of the body chiefly on the other limb, ſo that they bend the thigh of the affected ſide forwards, in order to touch the ground only lightly with the foot. This is at all times found to be the moſt eaſy poſition of the limb, and every attempt to put the member in a ſtraight poſture gives conſiderable pain.

Such is the firſt ſtage of the diſeaſe in its ordinary form, in which we generally find the health little diſturbed.

When the hip is touched, the patient does not in general ſuffer any particular pain, unleſs the preſſure be applied to the front of the joint, the part which is undoubtedly the moſt ſuperficial. Yet it deſerves notice, that a few inſtances do occur, in which all the ſoft parts ſurrounding the joint are tenſe, exceedingly painful when handled, and in which the integuments are even tinged with a light pink colour.

It remains for us to deſcribe the ſecond ſtage of the diſeaſe, or that which is attended with ſuppuration.

The ſymptoms which are the fore-runners of the formation of pus, are different in different caſes. This variety depends upon the preſence of acute or only chronic inflammation. When the former occurs, the parts ſurrounding the joint become tenſe and extremely painful; the ſkin is even reddiſh, and the patient experiences an attack of inflammatory fever. As the local pain abates, rigors take place, a ſwelling forms in the vicinity of the joint, and very ſoon points.

When the abſceſs is the conſequence of that languid kind of inflammation which uſually occaſions ſcrofulous collections of matter, there is not ſo remarkable an increaſe of pain in the articulation, before the commencement of ſuppuration. Startings and other ſpaſmodic complaints have been ſet down as the moſt certain ſigns of the formation of matter in this diſeaſe. When the pus is formed in this ſlow manner, it does not make its way to the ſurface of the body ſo quickly, as when the abſceſs has been the immediate reſult of an attack of active inflammation on the morbid joint. A large fluctuating tumour preſents itſelf; but it does not directly point. The patient ſuffers greater uneaſineſs in the part; yet his ſenſations do not amount to that acute deſcription of tenderneſs, which affects in the foregoing inſtance not only the deep, but alſo the moſt ſuperficial parts around the articulation.

At length the limb becomes ſhortened, and this circumſtance, when the retraction is very conſiderable, ariſes from nothing leſs, than an actual diſlocation of the head of the thigh bone, in conſequence of the deſtruction of the cartilages, ligaments, and articular cavity. The ſhortening of the limb may happen before ſuppuration as well as after it. There are inſtances, in which the head of the bone is diſlocated, and anchyloſis enſues without the occurrence of any abſceſs at all.

Sometimes, before matter is formed, the patient is ſeriouſly dejected by hectic ſymptoms. In the ſuppurative ſtage of the diſtemper, theſe effects on the conſtitution always become worſe. The patient loſes his appetite, cannot ſleep, has a ſmall frequent pulſe, colliquative ſweats; and, too often, a very obſtinate and debilitating diarrhœa.

The openings through which the abſceſs is diſcharged continue, in moſt inſtances, to emit an unhealthy kind of matter for a long time after their firſt formation, becoming in fact the terminations of ſinuſes, which lead down to the diſeaſed joint.

When the diſeaſe follows external violence, the inability of uſing the limb is ſaid by Sabatier not to be ſo complete, as when that ſymptom depends upon a fracture of the neck of the thigh bone; a circumſtance, which may aſſiſt the judgment of the ſurgeon in any doubtful caſe.

When a diſeaſed hip is examined after death, collections of matter are often ſeen on the glutei muſcles, on the dorſum of the os ilium, and in the acetabulum. Sometimes, the muſcles at the upper and fore-part of the thigh are covered with pus. The femur is frequently found drawn up on the external ſurface of the ilium. The cartilage which covers the head of the thigh bone is occaſionally quite deſtroyed, while the round ball itſelf is marked with deep excavations, the effect of caries. The acetabulum is often totally deſtroyed, ſo that the os femoris, not being confined in the articular cavity, is pulled upwards by the muſcles. Even the outſide of the ilium is ſometimes affected with a kind of caries.

According to Mr. Ford, the os innominatum is always more extenſively carious than the thigh bone. We have ſeen a caſe, where the head of the latter bone was quite perfect, notwithſtanding the acetabulum was completely annihilated. If this ſtatement be generally, or even frequently correct, it muſt refute the doctrine of De Haen, that the diſtemper begins in the ſoft parts, at the ſame time, that it diſplays the abſurdity of all thoughts of undertaking amputation at the hip, ſince moſt of the diſeaſe, ſituated on the bones of the pelvis, could not be taken away.

The remote cauſes of the hip diſeaſe are very imperfectly underſtood. External violence is undoubtedly one, and the teſtimony of numerous reſpectable writers confirms, that lying down on the damp ground in ſummer time, and, indeed, all kinds of expoſure to damp and cold, are frequently conducive to the origin of the diſorder. For this reaſon, the lower orders of ſociety are rather more ſubject to the affliction than the higher claſſes. The particularities, however, in the affected joint, or, in the conſtitution, which cauſe the diſeaſe to take place in ſome perſons, and not in others, though ſimilarly circumſtanced in life, are perhaps beyond the reach of human inveſtigation. A ſcrofulous habit is certainly one prediſpoſing circumſtance; but the diſeaſe often takes place without any ſuſpicion of ſcrofula, and without any palpable cauſe whatever.

When the diſeaſe is attended with a degree of active inflammation, the moſt advantageous treatment is topical bleeding with leeches, cupping the circumference of the affected joint, and applying the ſaturnine lotion. When the pain is ſevere, the hip may be fomented in the morning and evening, and an opiate may be adminiſtered at night. Care muſt be taken to keep the bowels open with mild purgatives.

The foregoing plan is always highly beneficial, while there are manifeſt marks of active inflammation about the joint. But it is not to be continued after ſuch ſtate has ſubſided. Morbid anatomy tends to ſhew, that the hip diſeaſe conſiſts in the ſame alteration of the bones, ligaments, and cartilages, as we find prevails in the generality of white ſwellings. Experience proves, that both diſeaſes ought to be treated on ſimilar principles. The plan, therefore, on which the beſt ſurgeons place the greateſt reliance, is the endeavour to ſtop the progreſs of the diſeaſe by making an iſſue with cauſtic juſt behind and below the great trochanter. This iſſue is to be kept open with peas. The benefit which it effects, is accompliſhed not merely through the diſcharge that is produced, but alſo on the principle of counter irritation. For nothing is more certain in medical ſcience, than the frequent poſſibility of arreſting and ſubduing one diſeaſe by the artificial formation of another. In general, it will be requiſite to keep the iſſue open for ſeveral months, or even a year or two, before the diſtemper is effectually checked. During all this time, the patient ſhould be adviſed to reſt the limb as much as poſſible.

The efficacy of the Bath water, in the cure of the hip diſeaſe, has been much praiſed by Drs. Oliver, Charlton, and Falconer. The patient is put into a warm bath for 15 or 25 minutes, two or three times a week. It is to be noticed, that the Bath water is only recommended as an external application, and merely in the early ſtage of the diſeaſe, before ſuppuration has commenced. We ſuſpect, that many caſes, which have been ſet down as cured by the Bath water, have been rheumatic affections; and we believe that any warm bathing would have had equal power over the hip diſeaſe.

When abſceſſes form, the ſurgeon ſhould let out the matter, and apply a poultice. The iſſue, however, is not to be diſcontinued; or, if the inflammation or any other circumſtance ſhould compel the ſurgeon to heal it for a time, it will be proper to make another as ſoon as the joint is in a more eaſy ſtate. We ſcarcely need obſerve how neceſſary it is to ſupport the patient's ſtrength with tonics, good air, eligible nouriſhment, &c. when hectical ſymptoms prevail. Pain is to be appeaſed, and ſleep procured by opium. See Ford on the Diſeaſe of the Hip-joint, Falconer on Iſchias, Crowther on White Swelling, edit. 2. Samuel Cooper on the Diſeaſes of the Joints.

Hip-*mould*, in *Building*, is by ſome uſed for the back of the hip. Others underſtand it as a prototype, or pattern, commonly made of a piece of thin wainſcot, by which the back and the ſides of the hip are ſet out.

Hip-*ſhot*, a diſorder of a horſe, when he has wrung or ſprained his haunches or hips, ſo as to relax the ligaments that are to keep the bone in its due place.

The ſigns are, that the horſe will halt much, and go aſidelong, trailing his leg after him; and the hip which is hurt will be lower than the other, the fleſh falling away on the ſide of his buttock.

Hip-*tiles*. See Tiles.

HIPPA, in *Zoology*. See Cancer.

HIPPAGOGA, in *Antiquity*, a veſſel uſed in tranſporting horſes. It was otherwiſe called hippago.

HIPPARCHION and Ruffinus, in *Biography*, celebrated performers on the lyre, meeting in contention for the prize at the public games, Hipparchion was ſo terrified at the ſight of the crowd in the theatre, that he was utterly unable to diſpute the premium, which was beſtowed on Ruffinus. Hence the name of Hipparchion became proverbial for any one who promiſed much, and performed nothing.

HIPPARCHIA. See Crates.

HIPPARCHUS, an ancient aſtronomer, was born at Nice, in Bithynia, and flouriſhed between the 154th and 163d Olympiads. He was the firſt perſon who attempted to count the number of the fixed ſtars; and his catalogue is ſtill preſerved in Ptolemy's "Almageſt," where they are ſet down with their longitudes and apparent magnitudes. According to Pliny he foretold the courſe of the ſun and moon for 600 years; he predicted the times of eclipſes, and taught mankind that they ought not to be alarmed at the recurrence of ſuch phenomena. Thales was the firſt among the Greeks who could foretel the approach of an eclipſe; and among the Romans, Sulpitius Gallus began to be ſucceſsful in that kind of prediction, and he made a ſeaſonable eſſay of his ſkill on the night before the day in which the deciſive battle againſt Perſeus was fought. Hipparchus came after theſe, and greatly improved that ſcience, making ephemerides, and other learned and uſeful helps to the practice of aſtronomy. He diſcovered a new ſtar; and he is memorable for having been the firſt who diſcovered the Preceſſion *of the Equinoxes*, which ſee. He endeavoured to reduce to rule the many diſcoveries which he had made, and invented new inſtruments by which he marked the places of celeſtial objects, and their magnitudes. Hipparchus made his firſt obſervations in the iſle of Rhodes, but he afterwards purſued his ſtudies in Bithynia and Alexandria. His commentary upon the phenomena of Aratus, which is a kind of criticiſm on that poem, is ſtill extant. This commentary was firſt publiſhed by Peter Victorius at Florence, about the middle of the 16th century; but a more correct edition of it was given by father Petau, with a Latin verſion and notes, in his Uranologia, publiſhed at Paris, 1650. Hipparchus was author of many other works, which were highly ſpoken of by the ancients, but which are now loſt. Every man of ſcience has without heſitation agreed in rendering a juſt tribute to the praiſe of this aſtronomer, on account of the obligations which this kind of knowledge is under to him. He is likewiſe celebrated for his ardent patriotiſm and public ſpirit, under the influence of which he is ſaid to have been greatly inſtrumental in delivering his country from tyranny. He is thought to have died about 125 years before the Chriſtian era, and ſtatues were erected to his memory. Bayle. Hutton's Math. Dict.

HIPPARCHUS's *Period.* See PERIOD.

HIPPASUS, in *Biography*, is enumerated among the Greek writers on muſic whoſe works are loſt. He was a native of Metapontus, a diſciple of Pythagoras, and, according to Theon of Smyrna, an excellent muſician.

HIPPED ROOF, in *Architecture*, is that whoſe ends riſe immediately from the wall plate, with the ſame inclination to the horizon as the other two ſides of the roof have.

Backing of a hip is the angle made on its upper edge, to range with the two ſides or planes of the roof between which it is placed.

Jack rafters are thoſe ſhort rafters fixed to hips equidiſtantly diſpoſed in the planes of the ſides and ends of the roof, and parallel to the common rafters, to fill up the triangular ſpaces, each of which is contained by a hip rafter, the adjoining common rafter and the wall plate between them.

The ſeat or baſe of the rafter is its ichnographic projection on the plane of the wall-head, or on any other horizontal plane.

The principal angles concerned in hipped roofing are, the angle which a common rafter makes with its ſeat on the plane of the wall-head; the vertical angle of the roof; the angle which a hip makes with the adjoining common rafter; the angles which a hip make with the wall plate on both ſides of it; the angle which a hip rafter makes with its ſeat; and the acute angle which a hip rafter makes with a vertical line. The principal lengths concerned are, the height of the roof; the length of the common rafters and their ſeats; the length of the hips and their ſeats; and, laſtly, the length of the wall plate contained between the lower end of a hip and the lower end of the adjacent common rafter.

The ſides and angles may be found by geometrical conſtruction or trigonometrical calculation. It is evident, that if the hipped end of a roof be cut off by a vertical plane parallel to the wall, through the upper extremity of the hips, it will form a rectangular pyramid, or one whoſe baſe is a rectangle. The baſe of this pyramid is bounded by the wall plate between the two hips on one ſide, and on the oppoſite ſide by the ſeat of the two adjoining common rafters; on the other two oppoſite ſides by that part of the wall plate on each ſide contained by the lower end of the hip and the next common rafter adjoining. One of the ſides is the iſoſceles triangle contained by the two adjoining common rafters with their ſeat; the oppoſite ſide is the hipped end of the roof, forming alſo an iſoſceles triangle; the other two oppoſite ſides are the right-angled triangles contained by the two hips and the two adjoining rafters on the ſide of the roof. This rectangular pyramid may be divided into three triangular pyramids by the two vertical triangular planes, formed by the hip rafters, their ſeats, and the common perpendicular from their vertex.

Two of theſe pyramids, when the plan of the building is a rectangle, are equal and oppoſite. In each of theſe equal and oppoſite pyramids the baſe is a right-angled triangle, contained by the ſeat of the hip rafter, the ſeat of the adjoining common rafter, and the part of the wall plate between the hip and the adjoining common rafter. One of the ſides is a right-angled triangle contained by the adjoining common rafter, its ſeat, and perpendicular; a ſecond ſide is a right-angled triangle contained by the common rafter, the hip rafters, and the wall plate between them; and the remaining third ſide is the triangle contained by the hip rafter, its ſeat and perpendicular. With regard to the remaining pyramid, its baſe is a right-angled triangle contained by the ſeats of the two hips and the wall plate between them, the right angle being that contained by the ſeats of the two hips; two of its ſides are the triangular planes paſſing the hip rafter, which are alſo common to the other two pyramids; its third ſide is the hipped end of the roof.

Given the plan of a building, or the form of a wall plate of a hipped roof, and the pitch of the roof, to find the various lengths and angles concerned, whether the roof is ſquare or bevel.

To find the Length of the Rafters Geometrically.—Let ABCD (*Pl.* LXXV.) be the plan. Draw E F parallel to the ſides A D and B C in the middle of the diſtance between them. On D C, as a diameter, deſcribe the ſemicircle D F C. Draw F D and F C, then the angle D F C is a right angle. Draw G F H perpendicular to E F, cutting the ſides A D and B C in G and H. From F E cut off F I equal to the height or pitch of the roof, and join G I. From F C cut off F K equal to F I, and join K D; then G I is the length of a common rafter, and D K that of the hip; for if the triangles G F I and D F K be turned round their ſeats, G F and D F, until their planes become perpendicular to the triangle G F D, the perpendicular F I will coincide with F K, and the point I will coincide with the point K; the lines G I and D K, repreſenting the rafters, will then be in their true poſition.

The ſame by Calculation.—$GI^2 = GF^2 + FI^2$ (Euclid I. 47), therefore $GI = (GF^2 + FI^2)^{\frac{1}{2}}$ the length of the common rafter, $DF^2 = GF^2 + GD^2$ the ſquare of the ſeat of the hip. $DK^2 = DF^2 + FK^2 = GF^2 + GD^2 + FI^2$, therefore $DK = \overline{GF^2 + GD^2 + FI^2}^{\frac{1}{2}}$.

In the ſame manner the other hip rafter C L is found, as alſo the hip rafters A M and B N.

To find the Backing of the Hips and the Shoulders of Jack Rafters and Purlins.

Geometrically.—Let it be required to find the backing of the hip rafter, whoſe ſeat is C F.

Imagine the triangle C F L to be raiſed upon its ſeat C F, until its plane becomes perpendicular to the plane of the wall plate A B C D, then there will be two right-angled ſolid angles; the three ſides of the one are the plane angles F C D, F C L, and the hypothenuſal plane angle D C L. In each of theſe ſolid angles the two ſides containing the right angle, *viz.* the plane angles F C H, F C D, and the perpendicular plane angle C F L, which is common to both, being given, to find the two oppoſite inclinations to the ſides F C H and F C D, and the remaining third ſides.

Now the angles G D C and H C D are biſected by the ſeats F D and F C of the hip rafters; for if E F is produced to meet D C in U, U will be the centre of the circle D F C; and U C, U F, U D, are equal to each other: and becauſe U F is equal to U C, the angle C F U is equal to F C U; but C F U is equal to the alternate angle F C H; therefore the angle F C U is equal to F C H: that is, the angle U C H is biſected by the ſeat F C of the hip rafter. In the ſame manner it may be ſhewn that U D G is biſected by the ſeat D F of the other hip rafter. From any point O in F C, draw O V perpendicular to L C, cutting it in P, and O W perpendicular to F C, cutting D C in W; from O C cut off O Q equal to O P. Join Q W, then O Q W will be the inclination oppoſite the plane angle F C U, and this is the angle which the end of the roof makes with the vertical triangle contained by the hip rafter, its ſeat and perpendicular. Produce W O to meet B C in X, and join Q X, then W Q X is the inclination of the two planes of a ſide, and end of the roof, whoſe interſections are B C and C D, on the plane of the wall-head. Now the angle W Q X, which is double the angle W Q O, is the backing of the hip. Make P V equal to Q W, and join C V, then will P C V be the angle contained by the two ſides L C, C D, or that of the hypothenuſal plane angle contained by the interſection B C, and the hip rafter L C. This angle may be otherwiſe found thus: produce G H to R; make C R equal to C L, then the angle H C R is equal to P C V. Now the angle H C R, or P C V, is the angle which the purlins (when one of their faces is in the ſide of the roof) makes with the hip rafter L C; and the angle C V P, or C R H, is the angle which a jack rafter makes with the ſame hip: in the ſame manner may the backings of the other hips be found. The other bevel of the jack rafters is the angle H I F. To find the other bevel for cutting the ſhoulder of the purlin proceed thus: on F, as a centre, with the diſtance F G, deſcribe the arc G Y; draw F Y perpendicular to G I; Y Z parallel to E F, cutting F D in Z, and Z & parallel to G H, cutting A D in &. Join & F, then G & F is the angle which the other ſide of the ſhoulder makes with the length of the purlin.

At the upper end of this diagram is ſhewn the manner of finding the two bevels for cutting the ſhoulder of the purlin againſt the hip rafter, when the ſide of the purlin is not in the plane of the ſide of the roof.

To find the ſame things by calculation.—The backing of the hip rafter, and hypothenuſal ſide, is obtained as follows: it has been ſhewn that the three plane angles, and the three inclinations of ſolid angles, conſiſting of three plane angles, are found exactly as the ſides and angles of ſpheric triangles, any three parts being given; the degrees of the plane angles being exactly the ſame as the ſides of the ſpheric triangle, and the inclinations the proper meaſures of the ſpheric angles: therefore if two of the plane angles ſhould be perpendicular to each other, the ſpheric triangle repreſenting this ſolid angle will have alſo two of its ſides perpendicular to each other. Now in this, there are given the two ſides containing the right angle to find the hypothenuſe and angles.

It is ſhewn by writers on ſpherical trigonometry, that in any right-angled ſpherical triangle, radius is to the coſine of either of the ſides, as the coſine of the other ſide to the coſine of the hypothenuſe. Suppoſe the plane angle F C L to be 27°, and the angle F C H 52°, to find the hypothenuſe and angles of a right-angled ſpherical triangle, one of whoſe legs is 27° and the other 52°, it will therefore be

As radius, ſine of 90° - - - - = 10.00000
Is to the coſine of F C L, 27° - = 9.94988
So is the coſine of F C H, 52° - - = 9.78934

19.73922
10.00000

To the coſine of the hypothenuſal ſide 56° 44′ - - - } = 9.73922

This aſcertains the angle which the jack rafter makes with the hip. Since all the ſides are now given, we ſhall have, by another well known property of the ſines of the ſides being as the ſines of the oppoſite angles, the following proportion,

As the ſine of the hypothenuſe 56° 44′ = 9.92227
Is to the ſine of a right angle, or 90° = 10.00000
So is the ſine of the ſide F C H, 52° = 9.89653

19.89653
9.92227

To the ſine of the oppoſite angle 70° 28′ = 9.97426

Therefore the backing is twice 70° 28′ = 140° 56′

In finding the angle oppoſite the ſide F C H, it was not neceſſary that the hypothenuſal ſide ſhould have firſt been found, it might have been found independently thus: the ſine of either of the ſides about the right angle is to radius, as the tangent of the remaining ſide is to the tangent of the angle oppoſite to that ſide; therefore

As the ſine of the ſide F C L, 27° - = 9.65705
Is to the tangent of the ſide F C H, 52° = 10.10719
So is radius, ſine of 90° - - - - = 10.00000

20.10719
9.65705

To the tangent of the angle oppoſite the ſide F C H, 70° 28′ - } = 10.45014

In the ſame manner may other bevels be found by trigonometrical calculations; but as ſuch extreme exactneſs is not neceſſary, the geometrical conſtructions ought to be well underſtood.

HIPPELAPHUS, among the *Ancient Zoologiſts*, was only the name of a large race of ſtags with longer hair on the neck, giving it the appearance of a mane. See Cervus *Elaphus*.

HIPPER River, in *Geography*, is a ſmall river which riſes in the Eaſt Moors of Derbyſhire, in the townſhip of Brampton, and falls into the Rother at the S.E. end of the town of Cheſterfield. This river collects all the rain waters of about 7000 acres of land, according to Mr. Farey's Report of Derbyſhire, vol. i., where the ſtrata are mentioned over which it flows. A great variety of manufactures are eſtabliſhed on this river in New or Little Brampton and Cheſterfield.

HIPPEUS, or Equinus, in *Phyſiology*, a ſort of comet which ſome writers ſuppoſe to bear a reſemblance in its tail to a horſe. But the ſhape of this kind of comet is not always alike; being ſometimes oval, and ſometimes imitating a rhomboides. Its train alſo is ſometimes ſpread from the front or fore-part, and ſometimes from the hind-part.

Hence this claſs of comets is diſtinguiſhed into equinus barbatus, equinus quadrangularis, and equinus ellipticus. See Comet.

HIPPI Promontorium, in *Ancient Geography*, *Ras-el-Hamrah*, a promontory of Africa, E. of the promontory of Tapſus, and N.W. of the promontory of Stoborrum.

HIPPIA, a town of Greece, in Theſſaly, in Perrhæbia. —Alſo, a fertile and delightful level country at the mouth of the Cephiſus.

Hippia, in *Botany*, a name which ſeems to have originated with Valerius Cordus for the common Chickweed, *Stellaria media*, Fl. Brit. See his Hiſt. Stirp. 159. It is ſaid by Ambroſinus to be derived from ἵππος, *a horſe*, becauſe it affords that animal a grateful food. Whatever truth there may be in this account, we are unable to trace the meaning of Linnæus in applying it to the little ſyngeneſious genus, reſembling Tanſy, of which we are here to treat.—Linn. Mant. 158. Schreb. 586. Willd. Sp. Pl. v. 3. 2382. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 278. Juſſ. 184. Lamarck. Dict. v. 3. 130. Illuſtr. t. 717. Gærtn. t. 164.—Claſs and order, *Syngeneſia Polygamia-neceſſaria*. Nat. Ord. *Compoſitæ Diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Calyx* hemiſpherical, of ſeveral ovate, ſomewhat imbricated, ſcales. *Cor.* compound, diſcoid; with numerous male florets in the diſk, and ten female ones in the circumference; the petal of the males is funnel-ſhaped, five-cleft, erect; that of the females obſolete, tubular, ſlightly three-cleft. *Stam.* Filaments in the male florets five, very ſhort; anthers ſtill ſhorter, united into a cylinder. *Piſt.* Germen in the female florets large, bordered; ſtyle cloven; ſtigmas erect. *Peric.* none, except the unchanged calyx. *Seeds* in the female florets oval, encompaſſed all round with a very broad margin, without any crown. *Recept.* naked.

Eſſ. Ch. Receptacle naked. Seed-down none. Seeds with a broad margin. Calyx hemiſpherical, ſomewhat imbricated. Florets of the radius ten, obſolete, obſcurely three-cleft.

1. H. *fruteſcens*. Linn. Mant. 291. Suppl. 390. (Tanacetum fruteſcens; Linn. Sp. Pl. 1183. T. africanum arboreſcens, foliis lavandulæ multifido folio; Comm. Hort. v. 2. 201. t. 101.)—Shrubby, erect, and hairy. Leaves pinnatifid. Flowers corymboſe.

A native of the Cape of Good Hope, flowering in our greenhouſes from February to Auguſt, and ſometimes perfecting ſeed in the autumn. The whole plant is clothed with ſoft ſhaggy hairs, eſpecially the young leaves and branches, and has the ſmell and taſte of common Tanſy. *Stem* ſhrubby, round, alternately branched, leafy, five or ſix feet high, with a brown bark. *Leaves* ſcattered, ſtalked, an inch or inch and half long, deeply and elegantly pinnatifid, their ſegments numerous, parallel, elliptical, entire, decurrent into the ſtalk. *Flowers* terminal, corymboſe, deep yellow, like Tanſy, but ſmaller. The chief beauty of the plant conſiſts in its foliage, which is ſo regularly cut as to be almoſt pectinate. Indeed Linnæus, thinking it at one time an *Eriocephalus*, named it *E. pectinifolius* in his Syſt. Nat. ed. 12. v. 2. 579.

2. H. *minuta*. Linn. Suppl. 389.—Herbaceous, procumbent, creeping. Leaves pinnate. Flower-ſtalks axillary, ſingle-flowered.—Sent by Mutis from New Granada. *Root* of very long fibres. *Stems* procumbent, creeping, a few inches in length, branched, round, hairy. *Leaves* oppoſite at the baſe of the branches, otherwiſe alternate, ſcarcely an inch long, pinnate or very deeply pinnatifid, their leaflets or lobes much reſembling thoſe of the former ſpecies, but ſometimes having one or two notches. They are hairy when young, nearly ſmooth when full-grown. *Footſtalks* rather longer than the leaves, ſheathing and membranous at the baſe. *Flower-ſtalks* axillary, longer than the leaves, deflexed, ſimple, ſlender, naked, ſolitary, each bearing an extremely ſmall yellowiſh *flower*, of the difficulty of examining which the younger Linnæus might well complain; but he has copied his father's manuſcript from the back of the ſpecimen, and poſſibly the whole was written by the latter, as was the caſe with the greater part of the *Supplementum*, though publiſhed in the name of the former. We have already pointed out a miſtake into which Juſſieu has been led reſpecting this plant. See GYMNOSTYLES *naſturtiifolia*.

3. H. *ſtolonifera*. Broter. Luſit. v. 1. 373. Phytogr. faſc. 1. 29. Willd. n. 3.—Herbaceous, procumbent, creeping. Leaves pinnatifid. Flowers ſeſſile at the root.—Frequent in Portugal, according to the worthy father Brotero, growing in moiſt ground, eſpecially where the ſoil is chalky, and flowering in winter, ſometimes ſo late as April. The plant is inſipid and inodorous. *Root* annual, fibrous, crowned with the ſeſſile *flowers*, and throwing out from beneath them a few ſhoots, ſcarcely above half an inch long. *Leaves* copious, radical, ſpreading in a circle, ſmooth or ſlightly downy, pinnatifid with five, ſeven, or only three lobes, which are very ſmall and linear-lanceolate. *Footſtalk* from half an inch to an inch long, being twice the length of the leaf, or more. *Florets* enveloped in down, all tubular; the females 40 or more, in the circumference; males ſeven or eight only, in the centre. *Corolla* of the females awl-ſhaped or briſtle-like, cloſely embracing the ſtyle, with a ſcarcely perceptible limb; that of the males funnel-ſhaped, apparently three-cleft. The *ſtyles* of the former all meet over the male florets in the centre, while the flower is in perfection. *Seeds* numerous, ſmooth, wedge-ſhaped, or obovato-triangular, the upper angles pointed; crowned with the ſtyle and a membranous partial calyx, without down, and winged longitudinally.—Such are the moſt important circumſtances in Brotero's deſcription, which certainly prove the plant a *Gymnoſtyles*, under which genus we ſhould have ranged it, had this account come under our notice before. It does not appear to be any of the ſpecies we have deſcribed, but makes a fourth, and the only European one. We have not however ſeen any ſpecimen.

4. H. *integrifolia*. Linn. Suppl. 389. (Grangea; Lamarck. Illuſtr. t. 699. f. 1.)—Roughiſh, upright. Leaves lyrate, unequally ſerrated; the upper ones undivided. Flowers in terminal cluſters.—Native of the Eaſt Indies? Our ſpecimen came from the Paris garden, as the *Grangea* of Juſſieu and Adanſon; we have already alluded to it under the firſt ſpecies of that genus; (ſee GRANGEA;) but were not then aware of its being figured as ſuch by Lamarck. The original ſpecimen, named by the younger Linnæus, is very bad, and the *leaves* were not perceived by him to be lyrate. He not unaptly compares them to thoſe of a nettle, which their deep unequal ſerratures reſemble. The *ſtem* is herbaceous, a foot or two high, roughiſh. *Leaves* alternate, ſtalked, two inches long and one broad. *Flowers* the ſize of a ſmall pea, in looſe, terminal, erect cluſters; their florets very numerous; receptacle convex; ſeeds obovate, bordered. We are certain this plant is not a *Grangea*, but dare not aver it to be a good *Hippia*, though we ſee no poſitive objection. The *ſeeds* indeed are much narrower than in *H. fruteſcens*.

5. H *bicolor*. (H. integrifolia; Ait. Hort. Kew. v. 3. 278. Sphæranthus africanus; Burm. Ind. 185. t. 60. f. 2, but not of Linnæus; Cotula bicolor; Willd. Sp. Pl. v. 3. 2171, excluding the ſynonym of Lamarck.)—Roughiſh, ſpreading. Leaves obovate, deeply ſerrated. Flowers in terminal, divaricated, leafy cluſters.—Native of the Eaſt Indies. We had it (as the plant adopted by Willdenow from Roth,) out of the ſtove of the Cambridge garden in October, 1805, and have no doubt of the ſynonyms of Burmann and Aiton. It appears ſufficiently diſtinct from the laſt deſcribed in its ſpreading mode of growth, paler colour, differently ſhaped and leſs divided leaves, whoſe ſerratures are more pointed, and in the divaricated cluſters. In genus it certainly accords with the *integrifolia*, which name would ſuit the preſent ſpecies better than that to which it is applied. S.

HIPPIAS, in *Biography*, a philoſopher of Elis, and a diſciple of Hegoſidamus; he was crowned at the Olympic games, and wrote upon muſic.

HIPPIATRICE, of ἱππος, *horſe*, and ιατρος, *phyſician*, the art of curing the diſeaſes of brutes, and particularly horſes.

This makes what we rather call the *farrier's art.* See Farrier.

HIPPION, in *Botany*, a name ſynonymous in ſome authors with Horſe Violet, derived from ἱππος, *a horſe*; but for whoſe application in the preſent inſtance we cannot account. It is retained by Schmidt in his Flora Boëmica, after Geſner, for the *Gentianæ* with a bearded corolla, of which he makes a diſtinct genus. Mr. Brown, however, Prodr. Nov. Holl. v. 1. 450, quotes the *Hippion* of Schmidt as a ſynonym of what he conſiders as the real *Gentianæ*, whoſe corolla is naked at its orifice.

HIPPIUM, in *Antiquity*, that part or tract of the *hippodrome* which was beaten with the horſes' feet. See Hippodrome.

HIPPO Diarrhytus, or *Zarytus*, in *Ancient Geography*. See Biserta.

Hippo-*Regius*, an ancient town of Africa, in that part of Numidia called the Eaſtern province or Conſtantina, ſituated near the ſea, on a bay in the vicinity of the promontory of Hippi. The ruins of this ancient city are ſpread over the neck of land that lies between the rivers Boo-jeemah and Seibouſe, which near the bank is plain and level, but riſes afterwards to a moderate elevation. They are about half a league in circuit, conſiſting of broken walls and ciſterns. This city was called Hippo Regius, not only in contradiſtinction to the Hippo Zarytus, but from its having been one of the royal cities of the Numidian kings. For Silius Italicus (l. iii. v. 259.) informs us, that it was formerly one of their favourite ſeats; and indeed if a city ſtrong and warlike, commodiouſly ſituated, as well for commerce as for hunting and diverſion, that enjoyed a healthful air, and took in at one view the ſea, a ſpacious harbour, a diverſity of mountains loaded with trees, and plains interſected by rivers, would fix the affection and attachment of the Numidian kings, Hippo had all theſe circumſtances to recommend it.

HIPPOBOSCA, in *Entomology*, a genus of the Diptera order, diſtinguiſhed by having the mouth furniſhed with a ſhort, ſtraight, and cylindrical two-valved ſucker, the valves of which are equal; the antennæ filiform; feet armed with numerous claws, and the body flat and hard. This is the Linnæan character, to which it is added by Scopoli that the roſtrum has only one briſtle. Geoffroy obſerves, that the hippoboſcæ are the only dipterous inſects that want ſtemmata, except the culices, and that their antennæ are ſetaceous, and compoſed of a ſingle hair. According to Schæffer the abdomen is as broad as the thorax. Fabricius adopts the genus as propoſed by Linnæus, with the following eſſential character. Beak ſhort, ſtraight, and bivalve, with the valves equal, and the antennæ filiform; adding, as a ſecondary character, that the body of the hippoboſca is ſmall, ovate, depreſſed, flat, glabrous, and immarginate: the head ſmall, rounded, and flat; the eyes ovate, lateral, and diſtant; thorax ovate; ſcutel large; and the wings two, membranaceous, and the length of the abdomen.

The hippoboſcæ are denominated "Spider flies" by ſome Engliſh writers, no doubt in conformity with the French of Reaumur, "mouches araignées." This is not a name, however, by which they are excluſively known in France, being called in Normandy "mouches bretonnes," and elſewhere "mouches d'Eſpagne." In England alſo they bear the name of horſe-flies, the largeſt ſpecies being extremely troubleſome to horſes. They haunt woods and marſhy places, and are commonly found attached to the bodies of quadrupeds and birds, the blood of which affords them their natural ſubſiſtence. In the act of feeding they thruſt their acute proboſcis into the ſkin, and occaſion a ſmarting ſenſation, ſimilar to that inflicted in the bite of a flea, but rather more pungent. They move ſluggiſhly, and with caution, and are at all times ſo firmly attached to the ſkin by the aſſiſtance of their numerous claws, that it is ſcarcely poſſible by any effort to remove them, unleſs by at the ſame time plucking out the fleſh to which they adhere. The ſpecies are not numerous.

Some modern writers divide the hippoboſcæ into three diſtinct genera, retaining to one the former term, and naming the other two *Ornithomyia* and *Melophagus*. The very cloſe affinity the two firſt mentioned bear to each other in external appearance ſeems ſcarcely to allow a deviation ſo remote from the example of Linnæus and Fabricius as that propoſed, and we rather wiſh to eſteem them as two diſtinct families of the ſame natural tribe than as diſtinct genera: the difference that prevails in the ſtructure of the antennæ in thoſe two families is certainly remarkable, and the very peculiar diſtinction of the head is alſo to be conſidered, one having ſtemmata on that part, and the other none. With regard to Melophagus, the diſſimilarity in its general appearance is far more ſtriking to the caſual obſerver, this, unlike the two former, being deſtitute of wings: in the ſtructure of the antennæ it agrees with H. equina, a ſpecies admitted by every writer under the name of hippoboſca. We ſhall conſider theſe new genera as ſectional diviſions of the hippoboſcæ in the ſubſequent arrangement.

* *Hippoboſca.* Winged; eyes very diſtinct; head without ſtemmata; antennæ in the form of a globoſe tubercle inſerted in a hollow at the baſe of the beak.

Equina. Wings obtuſe; thorax variegated; feet armed with four claws. Linn. *Horſe ſpider fly*, Donov. Br. Inſ.

Inhabits Europe, and infeſts cattle, hiding themſelves under the hairs, and attaching themſelves firmly to the ſkin by means of the double pair of crotchets or hooks of their feet: it is of a diſguſting form, flat, and hard, and, like the two ſucceeding ſpecies, not eaſily killed by preſſure. The head is brown; thorax brown, varied with yellowiſh, and a band of the ſame down the middle; wings hyaline, with a brown ſpot near the outer margin; legs annulated with yellow and brown. Length about three quarters of an inch.

* *Ornithomyia.* Winged; eyes very diſtinct; head furniſhed with ſtemmata; antennæ lamelliform and advanced.

Avicularia. Wings obtuſe; thorax immaculate. Linn. *Bird ſpider fly*, Donov. Br. Inſ. *Ornithomye verte*, Latr.

Infeſts birds as the former infeſts quadrupeds, ſecreting itſelf among the feathers, and ſubſiſting on their blood. The body is dull brown, with a greeniſh caſt; ſize inferior to the former; length about half an inch.

Hirundinis. Wings tapering to a point, feet with ſix claws. Linn. Donov. Br. Inſ.

Body brown tinged with blueiſh; abdomen darker. Like the preceding, infeſts birds, but more generally the ſwallow, and is often found in the neſt of the common European kind.

* *Melophagus.* No wings; eyes leſs diſtinct; antennæ in the form of a tubercle, lodged in a hollow; valves of the ſucker longer than the head.

Ovina. Body dull, teſtaceous. Linn. Donov. Br. Inſ. *Sheep ſpider fly*, *melophage*, Latr. *L'hippoboſcque des moutons.*

Found lodged among the wool of ſheep in Europe.

HIPPOCAMPUS, in *Ichthyology*, a ſpecies of *Syngnathus*; which ſee.

HIPPOCASTANUM, in *Botany*, from ἱππος, *a horſe*, and καστανοι, *a cheſnut*, the Horſe Cheſnut. Cluſius, in his Hiſt. Plant. v. 1. 8, ſays the name is a tranſlation of the

Turkiſh appellation of this tree, *at céſtaneſi*, or *ad caſtaneſi*, given to it becauſe the fruit was found good for the cough or broken wind in horſes. (See Æsculus.) Some have ſuppoſed this fine tree, ſo ornamental to our Engliſh plantations, parks, and avenues, a native of America; but it appears from the works of Cluſius to have been brought from Conſtantinople to Vienna, and was found wild by Mr. Hawkins, the companion of the late Dr. Sibthorp, on mount Pindus, of whoſe celebrated groves it makes a principal part. The greateſt wonder is, that no name or deſcription, applicable to ſo ſingular and beautiful a tree, ſhould be diſcoverable among the writings of the ancients, and that the epithet *pinifer* ſhould have been given to this famous mountain, but none expreſſive of what muſt conſtitute its great and peculiar beauty, the rich foliage and magnificent bloſſoms of the horſe-cheſnut. See Clusius.

HIPPOCENTAUR, formed of ἵππος, *horſe*, κεντεω, *pungo*, *I ſpur*, and ταυρος, *bull*, in *Antiquity*, a fabulous monſter, ſuppoſed to be half horſe and half man.

What gave occaſion to this fable was, that the people of Theſſaly, inhabiting near mount Pelion, became thus denominated, becauſe they were the firſt who taught the art of mounting on horſeback; which occaſioned ſome of their neighbours to imagine, that the horſe and man made but one animal.

The hippocentaurs ſhould ſeem to have differed from the centaurs, in this, that the latter only rode on bullocks, and the former on horſes, as the names themſelves intimate. (See Centaurs.) Under that article it has been ſhewn that the appellation was derived from the practice of breaking or mounting horſes, for which the Theſſalians were the moſt famous. Theſe horſemen afterwards, in order to acquire greater ſtrength and agility, performed a kind of exerciſe, in which they fought with bulls, which they pierced with their javelins, or overthrew by graſping them by the horns. Pliny informs us, not only that this exerciſe was common among the Theſſalians, who invented it, but alſo that it was one of the ſhows which Julius Cæſar exhibited to the Romans. It is very probable, therefore, that in ſpeaking of theſe Theſſalians, they added to the name of Hippios that of Centaur, and hence of theſe three words, ἵππιος, κεντέω, ταυρος, was compounded that of hippocentaur, a horſeman-bull-ſhooter. As theſe horſemen became formidable afterwards by their depredations, the equivocation which appeared in the name made them to be accounted monſters compounded of two natures. The poets availed themſelves of this idea; and as in other inſtances they gave the air of marvellous to the ſubjects of which they treated, they made no difficulty in taking horſemen for Centaurs. And theſe horſemen became giants both in hiſtory and fable.

On the medals of Gallienus is repreſented a centaur drawing a bow, or holding a globe in the right hand, and the helm of a ſhip in the left; with this inſcription, APOLLINI CONS. AUG. *To Apollo the conſervator of Auguſtus.* Triſtan conſiders both the one and the other as a ſymbol of the protection Gallienus received from Apollo in his wars againſt the Perſians.

HIPPOCEPHALOIDES, the *horſe-head ſtone.*

The word is derived from the Greek ἱππο-, *horſe*, and κεφαλη, *the head*; and is a name given by Dr. Plot to a ſtone found in Oxfordſhire, and many other places, and ſuppoſed to reſemble the head of a horſe in figure, though the truth is, it requires a very warm imagination to make out the reſemblance.

The ſtone is compoſed of the matter of the common coarſer quarry ſtone, and owes its figure to a ſhell of the cockle-kind, into which having been received at a time when it was ſoft and moiſt, it has taken the exact figure and lineaments of its inner parts. It is about the ſize of the larger bucarditæ, from an inch and a half to two inches and a half in length, and indeed very much reſembles that ſtone, having been formed wholly in the ſame manner, and in a ſhell of the ſame genus. Hill's Hiſt. of Foſſils, p. 646.

HIPPOCRAS, *Vinum Hippocraticum*, a kind of medicated wine.

Menage approves the conjecture of thoſe who derive hippocras from Hippocrates, as ſuppoſing him the inventor of it, but we may better deduce it from the manica Hippocratis, or Hippocrates's ſleeve, uſed in the filtration of it.

Hippocras is a drink compoſed of wine, with ſpices and other ingredients infuſed in it; much uſed among the French by way of a cordial dram after meals.

There are various kinds of hippocras, according to the kind of wine, and the other additional ingredients made uſe of; as white hippocras, red hippocras, claret hippocras, ſtrawberry hippocras, hippocras without wine, cyder hippocras, &c.

That directed in our late college diſpenſary, is to be made of cloves, ginger, cinnamon, and nutmegs, beat, infuſed in canary, with ſugar; to the infuſion, milk, a lemon, and ſome ſlips of roſemary, are to be put, and the whole ſtrained through a flannel. It is recommended as a cordial, and is good in paralytic, and all nervous caſes.

HIPPOCRATEA, in *Botany*, is ſo named in commemoration of Hippocrates, the moſt celebrated of ancient phyſicians; and univerſally termed the "father of phyſic."—This genus was called *Coa* by Plumier, from the circumſtance of Hippocrates having been born in the iſland of Cos, and therefore uſually known by the name of Hippocrates Coas.—Linn. Gen. 25. Schreb. 34. Jacq. Amer. 9. Willd. Sp. Pl. v. 1. 193. Vahl. Enum. v. 2. 26. Mart. Mill. Dict. v. 2. Juſſ. 251. Lamarck. Illuſtr. t. 28. (Coa; Plum. 6. t. 35. Bejuco; Lœfl. It. 314.) Claſs and order, *Triandria Monogynia*. Nat. Ord. *Tribilatæ*, Linn. *Aceræ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, ſpreading, minute, coloured, deciduous, deeply divided into five, roundiſh, ſpreading, obtuſe ſegments, larger than the corolla. *Cor.* Petals five, ovate, ſomewhat excavated at the tip. *Stam.* Filaments three, awl-ſhaped, erect, as long as the corolla; anthers broad, with a tranſverſe furrow. *Piſt.* Germen oval; ſtyle as long as the ſtamens; ſtigma obtuſe. *Peric.* Capſules three, elliptical, compreſſed, large, with two-valved cells; valves keeled and compreſſed. *Seeds* five in each capſule, oblong, with a membranaceous wing.

Eſſ. Ch. Calyx in five ſegments. Petals five. Nectary fleſhy, bearing the ſtamens. Capſules three, obcordate or elliptic, gaping in the middle.

Profeſſor Vahl has deſcribed eight ſpecies of this genus in his *Enumeratio Plantarum*, though Linnæus was only acquainted with *Hippocratea volubilis*, but as this is a genus very little known, and curious for being triandrous in a natural order that has uſually eight or ten ſtamens, we are induced to give an abſtract of all the ſpecies found in the former author, following the profeſſor's arrangement.

1. H. *obcordata*. Vahl. Enum. n. 1. (H. ſcandens; Jacq. Amer. 9. t. 9.)—"Leaves ovato-lanceolate, ſerrated. Capſules obcordate."—Native of South America. It flowers in April and December, and bears fruit in July.—*Branches* purpliſh. *Leaves* from one to three inches long, and little more than an inch broad, rounded at the baſe, a little pointed, entire in the lower part. *Stipula* ſolitary, minute,

nute, ſetaceous, placed in the axils of the leaves. *Flowers* inodorous, yellowiſh-green. *Seeds* brown.

2. H. *ovata.* Vahl. n. 2. (H. volubilis; Linn. Syſt. Veg. 83.)—" Leaves oblong or ovate, lanceolate or elliptic, ſerrated. Capſules oval."—A native of South America.—*Leaves* two or three inches long, obtuſe at each end, ſmooth above; their ſtalks purpliſh, channelled above. Branches of the *panicle* divaricated, and, like the flowers, ſlightly ferruginous and downy. *Capſules* about two inches long, ſcarcely an inch broad, very obtuſe, ſeldom emarginate.

3. H. *lævigata.* Vahl. n. 3.—" Leaves ovate-oblong, ſlightly crenate."—Native of Cayenne.—*Branches* ſlightly ferruginous and downy. *Leaves* three inches long, rather obtuſe, ſhining, of a reddiſh-brown underneath, gracefully veined; ſtalks purpliſh, ſmooth. The partial flower-ſtalks two, at the diviſions of the *panicle.* Infloreſcence very ſimilar to that of the laſt ſpecies.

4. H. *viridis.* Vahl. n. 4. Fl. Peruv. v. 1. 44. t. 74. f *a.* —" Leaves ovate, obtuſely pointed, ſerrated and entire. Foot-ſtalks ſhorter than the leaves. Capſules oval, emarginate."—Found in groves upon the Andes.—Whole plant ſmooth. *Branches* forked. *Leaves* ſpreading, ſometimes oblong, ſomewhat leathery, ſmooth above; leaf-ſtalks twiſted, ſhort. *Bracteas* ovate, acute, hollow. *Flowers* yellow. *Stamens* united into a ſort of cup, which includes the germen; anthers gaping at the top. *Germen* obovate, triangular. *Style* three-furrowed at the top; ſtigma triangular. *Capſules* an inch long.

5. H. *diſperma.* Vahl. n. 5. (H. indica; Willd. Sp. Pl. v. 1. 193.)—" Leaves elliptical, pointed, minutely ſerrated. Capſules lanceolate, with two ſeeds, obtuſe at each end."—Native of the Eaſt Indies.—Whole plant ſmooth. *Branches* round. *Leaves* two inches long, ſlightly ſerrated towards the end, acute, ſometimes rather obtuſe, membranaceous, pale green, a little nervoſe on the upper ſide. *Panicles* ſhorter than the leaves. *Flowers* ſmooth. *Capſules* an inch long, ſtriated, gaping in the middle.

A variety, *β*, of this ſpecies, called by Vahl *Euonymoides*, is deſcribed by that author " with oblong or obovate leaves, entire or emarginate at the top." This variety differs in having the branches more remote, and its leaves three or four times as ſmall as in the original; there are alſo fewer flowers in the panicles.

6. H. *paniculata.* Vahl. n. 6.—" Leaves oblong, acute at each end, obtuſely ſerrated."—Found at Sierra Leone, and deſcribed by Vahl from a ſpecimen in the Herbarium of Juſſieu.—*Branches* ſhining, much ſpreading, extended at the joints, compreſſed at the top. *Leaves* three or four inches long, membranaceous, pale green. *Flower-ſtalks* half as long as the leaves. Its *fruit* is not known.

7. H. *macrophylla.* Vahl. n. 7.—" Leaves oblong, pointed, entire, ſhining, obtuſe at the baſe."—This, like the laſt, is a native of Africa, and preſerved in the collection of Juſſieu. —*Leaves* five or ſix inches long, a little acuminated, membranaceous, pale green, ſhining above. The *fruit* has not been ſeen.

8. H. *comoſa.* Vahl. n. 8. Swartz. Prod. 17. Ind. Occ. v. 1. 77.—(Bejuco; Lœfl. It. 314.)—" Leaves ſomewhat heart-ſhaped or ovate, pointed, entire. Peduncles much-branched, capillary. Capſules oblong or obovate."—Native of woods in the interior of Hiſpaniola, flowering in February and perfecting fruit in the middle of ſummer. The natives of St. Domingo call it *Amandier des Bois.* *Stem* climbing to a conſiderable height. *Branches* divaricated, reflexed, pendulous. *Leaves* oppoſite, entire, ſmooth on both ſides, having ſhortiſh, round footſtalks. *Panicles* terminal, repeatedly ſubdivided, bearing numerous, ſingle-flowered, white peduncles. *Flowers* polygamous, moſt of them barren. *Petals* oblong, obtuſe, white, perſiſtent. *Filaments* inſerted into the interior margin of the nectary. *Capſules* ſlightly ſtriated, of two valves, gaping in the middle. *Nuts* four, oblong, angulated, at firſt ſoft, but growing harder as they ripen, winged at the ſide and top; kernels ſweetiſh and oily.

The general habit of this genus is climbing, with very ſpreading branches, round and ſmooth in the lower part, and ſomewhat ſquare at the upper. Leaves oppoſite, on foot-ſtalks, ſmooth on both ſides. Panicles axillary and terminal, oppoſite, dichotomous. Flowers ſmall. Capſules ſmooth.

HIPPOCRATES, in *Biography*, the moſt diſtinguiſhed of the ancient phyſicians, and uſually called the *father of phyſic*, was born in the iſland of Cos, in the firſt year of the 80th Olympiad, or about 460 years before Chriſt. He was of the family of the Aſclepiades, *i. e.* the deſcendants of Æſculapius; his father, Heraclides, being the ſeventeenth lineal deſcendant from that perſonage, and the ſixteenth from Podalirius, who, with his brother, Machaon, followed the army of the Greeks, in the Trojan war, according to Homer. In this family the profeſſion of phyſic had been hereditarily followed from Æſculapius downwards, and under their direction the Coan ſchool attained its high degree of eminence. His maternal anceſtry was alſo honourable; his mother, Phenarete, being reputed the 18th lineal deſcendant from Hercules. Born under theſe favourable circumſtances, ſurrounded from his infancy with all the objects of his ſtudies, and aided by the collective knowledge, as well as incited to reſearch by the fame of his anceſtors, Hippocrates devoted himſelf zealouſly to the cultivation of the art, which he was deſtined to refine and improve. Not content with adopting the empirical practice which was hereditary in his family, he ſtudied medicine under Herodicus, who had invented the gymnaſtic medicine, and was inſtructed in philoſophy and eloquence by Gorgias, a celebrated ſophiſt, and brother of the phyſician juſt mentioned. He is ſaid alſo to have been a pupil of Democritus, (Celſus, lib. i. præf.) which, however, is conſidered as improbable; and to have been a follower of the doctrines of Heraclitus. In whatever ſtudy he engaged, however, he appears to have been a true eclectic, to have thought for himſelf, and to have adopted only thoſe principles which appeared to be founded in ſound reaſon. Thus, while he elucidated the empirical doctrines handed down to him by the light of philoſophy, he corrected, or rather rejected, the falſe theories with which the philoſophers, who had no practical knowledge of diſeaſes, had loaded the ſcience of medicine, and brought it into the true path of obſervation, under the direction of reaſon, that is, of a rational experience. Hence he is ſaid to have been the firſt who ſeparated the ſcience of medicine from philoſophy, or rather from mere ſpeculation, which then aſſumed that name. (" Hippocrates Cous primus quidem, ex omnibus memoriæ dignis, ab ſtudio ſapientiæ diſciplinam hanc (ſcil. medicinam) ſeparavit, vir et arte et facundia inſignis." Celſus, loc. cit.) For he conſidered philoſophy and medicine as mutual aids to each other, and the proper union of the two as conferring a god-like qualification on man: " ἰατρὸς γὰρ φιλόσοφος ἰσόθεος." (Lib. De decenti ornatu.) Hence the phyſicians of the rational or dogmatic ſect (ſo called in oppoſition to the empiric ſect) always acknowledged Hippocrates as their leader, being the firſt who combined reaſoning with experience.

Of the events of his life little is known with certainty: for of thoſe that are recorded, ſome have a fabulous appearance, and ſome are actually inconſiſtent with our knowledge of hiſtory. It is certain, that, after the manner of thoſe times, he ſpent the greater part of his life in travelling; reſiding, however, for a conſiderable period, at various places, in which he was occupied in the practice of his art. In this way he viſited the greater part of Greece and Aſia Minor; but it appears from his writings that his chief abode was in the provinces of Theſſaly and Thrace, eſpecially at Lariſſa, the chief city of the former, where he compoſed ſeveral books. Almoſt all the caſes of diſeaſe, which are well deſcribed in his books "on epidemical diſorders," occurred during his practice in theſe provinces. According to Soranus, he ſpent ſome time at the court of Macedon, where he ſignalized himſelf, in conſultation with Euryphon, a ſenior phyſician, by detecting the origin of the malady of the young Perdiccas. His obſervation of the emotion of the prince on the appearance of Phila, a miſtreſs of his father, led him to pronounce that love alone was capable of curing the diſeaſe which it had occaſioned. His fame cauſed him to receive invitations from different cities of Greece. He is ſaid to have been requeſted by the inhabitants of Abdera to go and cure their celebrated fellow-citizen, Democritus, of the madneſs under which they ſuppoſed him to labour. The alleged letter of the Abderites on this occaſion is ſtill preſerved. On viſiting the philoſopher, Hippocrates pronounced him not mad; but, on the contrary, the wiſeſt man in their city. A ſpeech aſcribed to his ſon Theſſalus is alſo extant, in which the ſervices of Hippocrates to the Athenians are enumerated. It is here ſaid, that Illyria and Pæonia being ravaged by the plague, the inhabitants of thoſe countries offered large ſums of money to induce Hippocrates to come to their relief; but that certain winds which at that time prevailed, led him to foreſee that the peſtilence was likely to penetrate into Greece; he, therefore, refuſed to quit his own country, but ſent his two ſons, and his ſon-in-law, through the different provinces, to convey the proper inſtructions for avoiding the infection; he himſelf went to Theſſaly, and thence to Athens, where he conferred ſuch eminent ſervices on the citizens, that they iſſued a decree honouring him with a crown of gold, and initiating him and his family in the ſacred myſteries of Ceres and Proſerpine. Hippocrates is likewiſe reported to have refuſed an invitation from Artaxerxes, king of Perſia, accompanied by a promiſe of every reward and honour which he might deſire, to repair to his dominions during a ſeaſon of peſtilence. The letters alleged to have paſſed on this occaſion are extant, in one of which Hippocrates replies, that "he has food, clothing, and a habitation, in his own country; that it would be unworthy of him to aſpire to the wealth and grandeur of the Perſians, or to cure barbarians who were the enemies of Greece." The enraged king ordered the inhabitants of Cos to deliver up Hippocrates, or to expect the terrors of his vengeance: but the iſlanders declared their reſolution to defend the life and liberty of their valued countryman at all hazards, and nothing was attempted by the Perſian. Moſt of theſe ſtories, however, are deemed fictitious by the moſt intelligent critics. The cure of the young Perdiccas probably originated from the report of a ſimilar cure aſcribed to ERASISTRATUS (which ſee); and the interview with Democritus is not ſupported by any ſatisfactory evidence. The relation of the ſervices of Hippocrates, during the plague at Athens, is altogether irreconcileable with the accounts of Galen and of Thucydides: the latter of whom is ſilent as to the name of Hippocrates, and affirms that the diſeaſe was unchecked, and that the phyſicians were its firſt victims. Beſides, that plague commenced during the Peloponneſian war, in the 2d year of the 87th Olympiad, at which time Hippocrates was about thirty years old, and therefore could not have had two ſons or a ſon-in-law in a condition to practiſe. It is ſuppoſed by M. Le Clerc, that Aetius aſcribed to Hippocrates the operations during the plague at Athens, which Plutarch, with more appearance of truth, imputed to Acron of Agrigentum (ſee ACRON); and Dr. Ackermann juſtly conjectures, that theſe fables were all invented after the death of Hippocrates, and aſcribed to him by the followers of the Dogmatic ſect, of which, as we have already obſerved, he was regarded as the founder. (See Fabric. Biblioth. Græca. tom. ii. p. 512. edit. Harles.) The letters and other pieces, which are preſerved with the works of Hippocrates, under the title of τὰ ἐξωτικὰ, and on the authority of which theſe anecdotes are related, are generally deemed ſpurious.

After a long life ſpent in the ſucceſsful practice of his art, in perfecting his rational ſyſtem of medical inquiry, and in forming diſciples worthy to ſupply his place, Hippocrates died at Lariſſa in Theſſaly, at the age of 85, or 90, or, as others affirm, of 104, or even 109 years. He was buried between that city and Gyrtona. Beſides two ſons, Theſſalus and Draco, both eminent practitioners, he left a daughter, married to his favourite pupil, Polybus, who arranged and publiſhed the works of his great maſter; he left alſo a number of diſciples.

How dubious ſoever many of the circumſtances of the life of Hippocrates may be, it is not queſtioned that he acquired a reputation, which has ranked him high among the great men of Greece, and which may be traced from age to age, from the time in which he flouriſhed through all ſucceeding periods. He has not only paſſed, by almoſt univerſal conſent, for the father of phyſic and the prince of phyſicians, but his opinions were every where reſpected as oracles, not only in the ſchools of medicine, but in the courts of law. Philoſophers of every ſect were eager to read, to quote, and to comment upon his writings. He has ſhared with Plato the title of *Divine;* and not only ſtatues, but temples were erected to his memory, and his altars were covered with incenſe, like thoſe of Æſculapius himſelf. Indeed the qualifications and duties required in the character of the phyſician, were never more fully exemplified than in his conduct, or more eloquently deſcribed than by his pen. He had formed a very exalted notion of the dignity and uſefulneſs of his profeſſion, which is only lowered, he ſaid, in the public eſtimation, by the ignorance of its profeſſors; and he ſupported this dignity in his own perſon by the moſt rigid attention to the morality of private life, by great ſimplicity, candour, and benevolence in all his intercourſe with the ſick, and by unwearied zeal in inveſtigating the nature and progreſs of diſeaſes, and in adminiſtering to their cure. He is ſaid to have admitted no one to his inſtructions without the ſolemnity of an oath, the form of which is tranſmitted to us among his writings. In this the moſt religious attention to the advantages of the ſick, the ſtricteſt chaſtity, and inviolable ſecrecy, in regard to whatever it ſeems improper to divulge, are the principal points inculcated.

The books attributed to Hippocrates amount to ſeventy-two in number, of which, however, a conſiderable part are regarded as ſpurious; ſome containing opinions which were not prevalent till long after the age of Hippocrates, and ſome differing altogether in ſtyle and compoſition from the genuine writings of that maſter, which are compoſed in the Ionic dialect, and are diſtinguiſhed by a remarkable conciſeneſs, and, as it were, compreſſion of language, which at times, indeed, borders upon obſcurity. Some pieces have been obviouſly written after the commencement of the Chriſtian era, and Galen affirms that ſeveral interpolations and alterations were made by Dioſcorides and Artemidorus, ſurnamed Capito, in the time of Adrian. Polybus, the ſon-in-law of Hippocrates, who collected and edited his works, is believed to have written ſome of the pieces, and Theſſalus and Draco, his ſons, as well as Hippocrates III. and IV., his grandſons, are ſuppoſed to have written others, eſpecially ſeveral of the books of "Epidemics." Again, Hippocrates, the firſt of the name, and grandfather of the great Hippocrates, is the reputed author of the treatiſes Περὶ ἀγμῶν and Περὶ ἄρθρων, as well as of that Περὶ τέχνης: while ſome eſſays have been aſcribed to the phyſicians of the contemporary Cnidian ſchool.

The following works are generally deemed original productions of Hippocrates, the Coan: namely, 1. The eſſay "On Air, Waters, and Soils;" 2. The firſt and third books of "Epidemics;" 3. The book "On Prognoſtics;" 4. The firſt and ſecond books of "Predictions;" and 5. The books of "Aphoriſms;" but the two laſt contain many interpolations by the two writers above mentioned, and others; 6. The treatiſe "On the Diet in Acute Diſeaſes;" 7. That "On Wounds of the Head." Haller includes ſeveral more treatiſes in the liſt of genuine works of Hippocrates, which, however, have been diſputed, even from ancient times; ſuch as thoſe "On the Nature of Man;" "On the Humours;" "On Fractures;" "On the Joints;" and one or two others. Upon this ſubject the reader will find ample information in the able and learned eſſay of Dr. Ackermann, on the life and writings of Hippocrates, printed in Fabricius's Bibliotheca Græca, (4th edit. by Harles) tom. ii.:—alſo in Haller's Biblioth. Anat. Med. et Chirurg. Gælicke Hiſtor. Med. Period. 5ta. Le Clerc. Hiſt. de la Médecine, p. 1. liv. iii. chap. 30.

The prodigious degree of authority, ſo long attached to the writings of Hippocrates, has occaſioned ſuch a multitude of editions, verſions, commentaries, diſſertations, &c. that many pages would be required to enumerate them. Haller has beſtowed much labour upon this object, and may be conſulted by the curious. We muſt confine ourſelves here to a curſory notice of the principal editions of the whole works.

The *Greek editions* are thoſe of Aldus, at Venice, in 1526, folio; and of Frobenius at Baſle, in 1538, folio.

The *Latin editions* are thoſe of Cratander, at Baſle, in 1526, folio, tranſlated by ſeveral hands;—of M. F. Calous, at Rome, 1525 and 1549, tranſlated from MSS. in the Vatican, by order of pope Clement VII.;—of J. Cornarius, at Venice, in 1545, 8vo. whoſe verſion has been frequently reprinted; and the verſion of Anutius Foëſius, at Francfort, 1596, 8vo. by Wechel.

The *Greek and Latin editions* are thoſe of Hieronymus Mercurialis, at Venice, 1578, folio;—of Zwinger, with the verſion of Cornarius, at Baſle, 1579, folio;—of Anutius Foëſius, at Francfort, 1595, ſeveral times reprinted;—of J. A. Vander Linden, alſo with the Latin verſion of Cornarius, at Leyden, 1665, 2 vols. 8vo. reprinted at Venice, 1757, in 2 vols. 4to.;—of Renatus Chartrier, together with the works of Galen, at Paris, in 14 vols. folio;—and of Steph. Mack, at Vienna, 1743, 1749, and 1759, 2 vols. folio.

Doctrines of Hippocrates.—To give a minute detail of the extent of the knowledge of Hippocrates in medicine, and in the collateral branches of anatomy, phyſiology, &c. as it may be collected from his various treatiſes, would be to write a volume on the ſubject. We muſt, therefore, limit ourſelves to an outline of his general precepts, referring thoſe of our readers, who may wiſh for a more ample view of them, to the works above-mentioned as genuine, or to the writers quoted in the courſe of this article. The anatomical knowledge of Hippocrates was neceſſarily limited by the prejudices of the times in which he lived, when the human body had never been diſſected for the purpoſes of anatomical enquiry; Eraſiſtratus and Herophilus, as we have ſtated, were the firſt to whom this permiſſion was given. His knowledge of the internal organs could only, therefore, be derived from accident, or a compariſon with thoſe of other animals. Hence, much of his phyſiological doctrines, and of his opinions reſpecting the cauſes and ſeats of diſeaſe, muſt neceſſarily be erroneous, and the whole extremely defective; eſpecially, when to ignorance of anatomy, the general deficiency of the age, in regard to the properties of the external world, is added. But by unceaſing obſervation of the phenomena of health and diſeaſe, Hippocrates in a great meaſure ſupplied the want of ſuch knowledge; ſo that his pathology and principles of cure bear, in many inſtances, a ſurpriſing reſemblance to thoſe of our own times, notwithſtanding our knowledge of the intimate ſtructure of the human body, and the general improvements in the philoſophy of nature.

Hippocrates conſidered the functions of the body as under the direction of an intelligent or inſtinctive principle, which he called *nature.* To this principle he aſcribed the "diſtribution of the blood, the ſpirits, and heat, to the different parts of the body, which receive by theſe means life and feeling." (Lib. de Alimento.) "This faculty," he ſaid, "nouriſhes, preſerves, and cauſes the growth of all the parts." Its mode of operation he conceived to conſiſt in attracting, preparing, or changing whatever was uſeful, and in rejecting whatever was injurious or ſuperfluous, after having ſeparated it from the uſeful; and this he ſuppoſed to be effected by a ſort of affinity and repulſion in ſimilar and diſſimilar parts. This doctrine, under various modifications, has paſſed through all medical ſyſtems, differing in many inſtances only in the change of names; thus, in the "Nature" of Hippocrates, we ſee the "Archæus," the "vital principle," the "ſpirit of animation," the "*vis medicatrix naturæ,*" of the moſt enlightened medical philoſophers of later times. It is not eaſy to collect an accurate view of the anatomy of Hippocrates, ſince different ſtatements on many points are to be found in different parts of the works aſcribed to him; it is to be regretted, that the book written by Galen, "De Anatomia Hippocratis," is loſt. With reſpect to the *brain,* it does not appear that Hippocrates had the leaſt ſuſpicion of its connection with ſenſibility and underſtanding; indeed, ſo far from conſidering it as the peculiar ſeat of the thinking faculty, he places this faculty in the left ventricle of the heart. (Lib. De Corde.) He conſidered the brain as a glandular body, from its texture, and as a receptacle of redundant moiſture, collected by the condenſation of hot vapours, which it diſcharges again in defluxions and catarrhs. (Lib. De Glandulis.) In deſcribing the optic nerve, he repreſents it as a mere tube, through which the aqueous humour is diſtilled into the eye. But it ſhould be obſerved, that the book *De Glandulis* is deemed ſpurious by Galen; and that, *De Corde,* in which the ſtructure of the heart is rather minutely deſcribed, is neither mentioned by Erotian nor by Galen. The heart ſeems to have been regarded, at that time, as the organ for mixing with the blood ſome aërial principle, drawn from the lungs by its auricles, which are deſcribed as inflaters, or bellows, calculated for that purpoſe. Indeed, whatever was known to the ancients in regard to the motion of the blood, ſeems to have conſiſted in ſome vague idea of regurgitation, or a certain flux and reflux, barely ſufficient to prevent the ſtagnation of the contents of the veſſels. The lungs were deemed by Hippocrates the abſorbers and condenſers of ſuperfluous humours, and the moderators of internal heat; the liver, as the ſource of ſanguification and of heat, in common with the other abdominal viſcera. His phyſiology of generation indicates his imperfect knowledge of the organs concerned in that proceſs ; he had an extraordinary notion of the ſemen being prepared in the brain, and conveyed by the ſpinal marrow to the veſſels provided for its reception. He appears to have had no accurate ideas of muſcles or of muſcular motion, though he was acquainted with the number, figure, and connection of the bones.

The fluids were divided by Hippocrates into the four humours, blood, phlegm, yellow, and black bile (Lib. De Natura Hominis) ; to which he aſcribes peculiar properties of hot, cold, cold, dry, and moiſt, in different combinations. He conſidered health as the reſult of a due temperament and proportion of theſe ſeveral fluids, both in reſpect to quantity and quality ; and looked for the ſource of diſeaſe in the exceſs, defect, or depravation of any or all of theſe humours. He, likewiſe, included in his ſyſtem an analogy or connection between the four humours and the four ſeaſons of the year, as well as the four ages of man. Thus phlegm, which is the coldeſt humour, he believed to be increaſed during the winter and in old age ; whence at thoſe periods pituitous diſeaſes were prevalent, ſuch as expectorations, œdema, &c. In the ſpring, the blood begins to be redundant, eſpecially in young people, who then ſuffer bleedings from the noſe, dyſentery, &c. As the ſummer and autumn advance, the diſpoſition to bilious diſeaſes augmented, bilious evacuations occur ſpontaneouſly, and are procured by medicine. We have ſeen how this doctrine, of the four humours, and four qualities, when extended to all the agents employed in medicine by Galen, became the prevalent code of phyſic for thirteen centuries ; nor is it long ſince the relics of it yielded to the influence of experimental ſcience. See GALENICAL *Syſtem*.

But it is chiefly in matters of fact and obſervation that ſucceeding ages were indebted to the genius of Hippocrates, and in which the influence of his authority is ſtill extenſively viſible in the language of medical ſcience. He divided the cauſes of diſeaſes into external, including the influence of air, exerciſe, reſt, ſleep, and watching ; and internal, comprehending the food, drink, ſecretions, retentions, and paſſions of the mind. He divided diſeaſes themſelves into *epidemic*, *endemic*, and *ſporadic*, according to the preſent ſignification of thoſe terms ; and again into *acute* and *chronic*, limiting the former to the duration of fourteen days. He, likewiſe, divided the duration of an acute diſeaſe into four ſtages, the beginning, increaſe, height, and decline. It was in the third of theſe ſtages that he conceived the *concoction* of the morbid humours to be accompliſhed, and between this and the laſt ſtage, when he expected ſome indication from nature, by what outlet the morbific matter was to be expelled, which conſtituted the *criſis* of the diſorder, and which he was careful not to interrupt. (See CONCOCTION and CRISIS.) Theſe *critical* diſcharges and changes he was led, partly by experience, and partly by hypotheſis, to expect on particular days ; and many of his rules of prognoſis in acute diſeaſes, were built upon the obſervation of the changes of ſymptoms on ſuch days. This doctrine, however, we have already diſcuſſed at length (ſee CRITICAL *Days*) ; and ſhall only remark, that the notion of a concoction and critical diſcharge of peccant matter, as the ſource of the phenomena of febrile and inflammatory diſeaſes, continued, under ſome modifications, to be the leading feature in medical ſyſtems to the time of Hoffmann ; that even Dr. Cullen did not altogether reject it ; and that it ſtill exiſts in popular language, and in vulgar medical opinions.

To the induſtry of Hippocrates we are indebted probably for an account of all diſeaſes which came under his inſpection ; and of the whole number, the greateſt part are ſtill characterized by the names invented or adopted by him, and not more than five or ſix of them appear to be extinguiſhed or unknown. Le Clerc has occupied a long chapter in enumerating the diſeaſes which ſtill retain the appellations given them by the father of phyſic. (See Hiſt. de la Médecine, p. 1. liv. iii. chap. 8. ; alſo, Gælicke, loc. cit. pp. 577—600.) But a diſtinguiſhing feature in the pathological talent of Hippocrates was his ſkill in diagnoſis and prognoſis ; his ſingular and conſtant care in watching all the minute changes in diſeaſe, having obtained for him a critical knowledge of ſymptoms, which enabled him not only to diſcriminate one diſeaſe from another, but to foreſee almoſt all their variations and terminations. On this point, Celſus admits that Hippocrates ſtood unrivalled by any of his ſucceſſors : " cum recentiores quoque medici, quamvis in curationibus mutarint, tamen hæc illum optime præſagiſſe fateantur." (De Medicinâ, lib. ii. Præf.) He carefully noticed a multitude of ſigns, which eſcaped the eye of ſuperficial obſervers. In a number of little peculiarities of mind and body, in the poſition of the limbs, (ſee DECUBITUS,) in the voluntary and involuntary motions, and the expreſſions of countenance, he ſhewed that indications of great importance might be diſcerned. But his moſt certain prognoſis was founded on the nature of the ſecretions, and of the urinary and alvine diſcharges, the various appearances of which ſupplied him with ſuch rational grounds of judgment, as ſucceeding inveſtigation has ſcarcely been able to impeach. His books of " Aphoriſms," and " Prognoſtics," contain the principal ſummary of his experience in ſymptomatology. The books of " Predictions," however, and of " Coan Prognoſtics," contain many erroneous precepts, whence Galen doubts their authenticity, and conſiders all that is valuable in them, as having been compiled from the two former books, and the books of " Epidemics." It has been diſputed among writers, whether Hippocrates had any knowledge of the pulſe : and although the affirmative ſeems probable, it is obvious that he did not lay much ſtreſs upon it in forming his indications.

With reſpect to the practice of Hippocrates, the length, to which this article has already extended, compels us to be brief. It would appear, indeed, that he conſidered it to be the duty of a phyſician, rather to watch patiently the progreſs of the operations of the conſtitution, and to remove impediments and aid the ſalutary actions, than to excite any decided changes by the action of powerful medicines. His obſervations on the powers of nature, and on the wiſdom of truſting to her efforts, in preference to the haſty, violent, or uncertain aſſiſtance of art, are frequently repeated. His general principles of cure are ſtated in the following axioms : " that as contraries are cured by contraries, ſo cold is the remedy for heat, and heat for cold ; evacuation will cure repletion, and repletion will repair the loſs ſuſtained from evacuation : that the art of medicine conſiſts in ſupplying deficiencies and retrenching ſuperfluities, in treating relaxation and contraction by their oppoſites, and in bringing back to their own channels fluids that are moving in improper courſes." (See Lib. de Priſca Medicinâ, De Natura Hominis, De Flatibus, &c.) Their dependence on the curative powers of nature led Hippocrates and the ancients in general to commence their therapeutic operations by the regulation of diet alone, in which, indeed, their whole practice often conſiſted. In contemplating their plans on this ſubject, modern feelings, and eſpecially thoſe of Engliſhmen, are appalled at the diſcipline which they inſtituted : for in very acute diſeaſes, they interdicted every kind of nutriment for the firſt three or four days ; allowing only as much thin drink as was ſufficient to moiſten the parched throat, which was often adminiſtered on a ſmall ſponge, to prevent the thirſty patient from ſwallowing too copious a draught. During this period it was intended to leave the active powers of the conſtitution at full liberty to drive out or change all morbid matter. But if this effect did not follow, or if the ſtrength of the patient failed in the trial, a more plentiful dilution was then allowed, with a beverage compoſed of eight parts of water, one of honey, and occaſionally one of vinegar, ſometimes enriched with the juice of acid fruits, cooling herbs, or ſome weak ſharp wine: ptiſan, or barley-water, was alſo a common beverage given by Hippocrates in acute diſeaſes. This plan, when neceſſary, was generally continued till the fourteenth day, (the reputed commencement of the chronic term,) when a more ſubſtantial diet was allowed, though ſtill without recourſe to any medicine, except gentle emetics and laxatives, the former conſiſting generally of a decoction of hyſſop with ſalt and vinegar, and the latter of expreſſed juice or decoction of common cabbage, or the herb mercury, or the more pleaſant exhibition of whey a little ſalted. For the laſt mentioned purpoſe glyſters of ſea-water, or of vetches boiled in milk with a little ſalt, were in common uſe.

When more powerful medicines became neceſſary, the ancients recurred to ſome of the moſt active purgatives hitherto diſcovered in the vegetable world; ſuch as black and white hellebore, elaterium, colocynth, and ſcammony, which were frequently adminiſtered in quick ſucceſſion: but theſe were never preſcribed to children, old people, or pregnant women. Notwithſtanding the caution, however, with which theſe draſtic medicines were given, it would ſeem that the moſt ſerious miſchief ſometimes enſued from their exceſſive operation; as Hippocrates mentions, among his aphoriſms, that "convulſions after taking hellebore are fatal." In order to excite perſpiration, he uſed every external means of increaſing heat, ſuch as warming the room, covering the patient, pouring hot water on the head and limbs, with a free internal uſe of heated liquors, and often of pure wine. And to increaſe the urine, he gave garlic, cucumbers, melons, celery, fennel, and other ſtrong flavoured herbs.

Hippocrates did not, however, excluſively confine himſelf to the adminiſtration of internal remedies, and the regulation of diet; he reſorted to external means of cure, in ſome of which he appears to have exceeded the bounds of modern activity, as far as he fell ſhort of them, in merely watching the efforts of the conſtitution in other caſes. He employed blood-letting (an operation, the origin of which is concealed by the remoteneſs of its antiquity) with great freedom. In extreme caſes of pain or inflammation, it was his cuſtom to open at once the veins of both arms, and let the blood flow till the patient fainted. He often likewiſe drew blood copiouſly from the legs and feet, to relieve complaints of the head and upper parts of the body, by large and deep inciſions with the knife, which he then covered with copper or other metallic veſſels, exhauſted of their air by fire, reſembling the cupping glaſſes of our own times. He ſeems, indeed, to have entertained many ſingular notions of the revulſion, which might thus be produced. For example, he recommends bleeding in the forehead for a head-ache in the occiput; and in order to reſtrain the catamenia, when exceſſive, he applied large cupping veſſels to the mammæ. (Aph. ſect. v. 60. and 68.) He laid down a maxim, which forms a contraſt with the inertneſs of ſome of his precepts, that "thoſe diſeaſes, which medicines will not cure, yield to the knife; and thoſe which the knife will not cure, may be removed by fire; but where this laſt and moſt powerful remedy fails, the malady muſt be deemed incurable." (Aph. § viii. 6.) Accordingly in obſtinate chronic caſes, the local bleedings above-mentioned were commonly ſucceeded by the actual cautery, which produced large and long continued diſcharges from the head, neck, breaſt, ſide, limbs, or other parts, to which the burning was freely applied. Nor did he even ſpare the bones, which he burnt, ſawed, and perforated without ſcruple; and he uſed the trepan itſelf in caſes of violent head-ache. It appears, as well from theſe operations, as from his rational directions for the treatment of fractures and diſlocations, and the frequent cautions that he gives reſpecting the danger and difficulty attending wounds and bruiſes in nervous or tendinous parts, that Hippocrates combined the practice of ſurgery with that of medicine. But it would ſeem that he thought the difficult operations of ſurgery ſhould be performed only by thoſe, who, by confining their profeſſional employment to this exerciſe alone, had attained a peculiar dexterity of hand; for he enjoins his diſciples, even in their inaugural oath, to forbear from performing the operation of lithotomy.

Theſe operations, as well as the number of medicines mentioned by Hippocrates, imply a conſiderable previous advancement both in internal and manual medicine. Le Clerc has enumerated upwards of three hundred articles of diet and the materia medica, which were employed by him, from the animal, vegetable, and mineral kingdoms. Among theſe are various preparations of iron, copper, lead, and ſilver, alum, nitre, vitriol, &c. Narcotics are mentioned by Hippocrates, and were certainly uſed in ancient times; but he ſeems to have been cautious in adminiſtering them, and it is even a matter of diſpute whether he ever employed opium, the moſt potent and uſeful of the whole claſs. Among the articles of diet, Hippocrates is careful to mention the properties of the fleſh of the dog, fox, horſe, and aſs, which implies that theſe viands were then in uſe, at leaſt among the people.

We ſhall conclude this account of Hippocrates, with the brief and philoſophical view of the ſcience of medicine, exhibited in his firſt Aphoriſm, which in the terſeneſs of its expreſſion cannot be imitated in a modern language. It contraſts the brevity of human life with the long experience neceſſary to the cultivation of the art of medicine; and reminds us of the difficulty of obtaining that ſolid experience in an art where opportunity is tranſient, where experiment itſelf is often hazardous and deceptive, and the inferences of the judgment, therefore, extremely difficult. "Vita brevis, ars longa, occaſio celeris, experimentum lubricum, judicium difficile." See Le Clerc, Gœlicke, and Fabricius, as above quoted; alſo the works of Hippocrates, Vita Hipp. à Sorano, Walker's Memoirs of Medicine. General Biog.

HIPPOCRATES's *Sleeve, manica Hippocratis,* a kind of filtre, or ſtraining-bag, formed by joining the oppoſite angles of a ſquare piece of flannel, in form of a pyramid, and uſed to percolate or ſtrain ſyrups, decoctions, &c. for clarification.

HIPPOCRATIA, in *Antiquity*, feaſts celebrated by the Arcadians in honour of the equeſtrian Neptune, from a notion that the deity conferred horſes on men. During the celebration of them, horſes were exempted from all labour, and were led in proceſſion through the ſtreets, ſuperbly harneſſed, and adorned with garlands of flowers. The Romans celebrated thoſe feaſts under the title of CONSUALIA.

HIPPOCRATICA FACIES. See FACIES *Hippocratica.*

HIPPOCRENE, derived from ιππος, *horſe*, and κρηνη, *fountain*, *q. d.* the fountain of the horſe Pegaſus, was a ſpring at the foot of mount Helicon, ſuppoſed to ſpring up upon

Pegaſus's ſtriking his foot againſt the mountain. See Helicon and Aganippe.

HIPPOCREPIS, in *Botany*, is derived from ἵππȣ κρηπὶς, *a horſe-ſhoe*, in alluſion to the particular conformation of its legumes, or rather the parts of its legumes, which reſemble as it were a connected ſeries of horſe-ſhoes. Few genera poſſeſs ſo decided and perceptible a character as this, by which it may be at once known, the horſe-ſhoe appearance of its fruit being ſo ſtriking, that no doubt can exiſt reſpecting any of the plants, which conſtitute the genus before us. Linn. Gen. 381. Schreb. 503. Willd. Sp. Pl. v. 3. 1158. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. v. 2. 777. Ait. Hort. Kew. v. 3. 60. Juſſ. 361. Lamarck Dict. v. 3. 131. Illuſtr. t. 630. (Ferrum equinum; Tourn. t. 225.)—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, permanent, five-toothed; the two upper teeth united or leſs divided. *Cor.* papilionaceous. Standard heart-ſhaped, with a claw the length of the calyx. Wings ovate-oblong, obtuſe. Keel lunulate, compreſſed. *Stam.* Filaments diadelphous (ſimple and nine-cleft) aſcending; anthers ſimple. *Piſt.* Germen ſlender, oblong, terminating in an awl-ſhaped, aſcending ſtyle; ſtigma perfectly ſimple. *Peric.* Legume compreſſed and membranaceous, very long, curved inwards, cut from the lower ſuture almoſt to the upper into ſeveral roundiſh ſinuſes, ſo as to conſiſt of ſeveral bluntly triangular joints, connected by the upper ſuture. *Seeds* ſolitary in each joint, oblong, incurved.

Eſſ. Ch. Legume jointed, compreſſed, curved, with many deep ſinuſes, in one of its edges.

1. H. *uniſiliquoſa*. Single-legumed Horſe-ſhoe Vetch.—Linn. Sp. Pl. 1049. (Ferrum equinum vulgare; Column. Ecphr. t. 300.)—"Legumes ſeſſile, ſolitary, ſtraight."—Native of Italy and Switzerland, where it flowers in June and July. *Root* ſimple, annual. *Stems* ſeveral, ſimple, various in length, the long linear cotyledons often remaining at their baſe. *Leaves* alternate, of about five pair of emarginate leaflets, and an odd one, nearly ſmooth and ſomewhat glaucous. *Flowers* axillary, ſolitary, nearly ſeſſile, ſmall, pale yellow. *Legumes* ſpreading, an inch and half long, frequently with briſtly tufts at the back, where every ſeed is lodged, their ſides curiouſly veined and ſtriated. An excellent figure of this ſpecies, under the name of *Ferrum equinum*, may be ſeen in Gerarde's Herbal. 1235, alſo in Rivinus, Pentap. Irreg. t. 97. f. 1.

2. *H. multiſiliquoſa*. Many-legumed Horſe-ſhoe Vetch.—Linn. Sp. Pl. 1050. Villars Dauph. v. 3. 400. (Ferrum equinum alterum πολυκέρατον; Column. Ecphr. t. 300).—"Legumes ſtalked, crowded, circular."—Native of a chalky ſoil in the ſouth of France, Spain, and Italy, flowering in July and Auguſt.—This is alſo annual, and very cloſely allied in habit to the laſt. *Stem* ſimple, furrowed. *Leaves* alternate, of about five pair of emarginate leaflets, and an odd one, ſmooth, bright green. *Flowers*, axillary, yellow, many-cluſtered, upon long peduncles. *Legumes* curved, ſometimes ſo much as to form a circle.

3. *H. balearica*. Shrubby Horſe-ſhoe Vetch—Willd. n. 3. Jacq. Ic. Bar. t. 149. Curt. Mag. t. 427.—"Legume pedunculated, crowded, ſmooth, lobed only in the outer margin."—Native of Minorca, flowering in May and June. *Root* woody, ſending forth aſcending *branches*. *Leaves* pinnate, ſmooth, of about eight pair of ovate-linear leaflets, with an odd one. *Peduncles* very long, terminated by an umbel of many yellow *flowers*, which have a faint, ſweet ſmell. *Legume* oblong, obtuſe, ſtraightiſh, or a little curved, ſinuated twice or thrice on the upper ſuture, ſmooth and browniſh furniſhed with ſhining, round, brown *ſeeds*.

4. *H. comoſa*. Tufted Horſe-ſhoe Vetch.—Linn. Sp. Pl. 1050. Sm. Fl. Brit. v. 2. 777. Engl. Bot. t. 31.—"Legumes pedunculated, cluſtered, curved, waved in the external margin."—Found on dry chalky banks in Kent, Cambridgeſhire, and other parts of England, bearing flowers from May to Auguſt. This is rather a ſcarce perennial, with a woody *root* and ſmooth herbage. *Stems* proſtrate, furrowed. *Leaves* pinnate, of numerous obovate emarginate leaflets, with an odd one. *Stipulas* lanceolate. *Peduncles* axillary, very long; partial-ſtalks ſhort, hairy. *Flowers* yellow. *Legumes* recurved, rough with little glands. *Seeds* kidney-ſhaped.

5. *H. barbata*. Bearded Horſe-ſhoe Vetch.—Loureir. Cochinch. v. 2. 453.—"Legume pedunculated, ſtraight, ſpike of flowers oblong, terminal."—Native of fields in Cochinchina.—*Stem* ſomewhat ſhrubby, four feet high, erect, round. *Leaves* ovate, entire, ſmooth, ternate, the middle leaflet larger. *Flowers* purple. *Legume* barbed, moſtly on the exterior ſuture, and deeply emarginate. *Seeds* angularly kidney-ſhaped, ſmall, compreſſed.—This ſpecies has not yet been introduced into Europe. We know it only from Loureiro.

HIPPODROME, Hippodromus, compoſed of ἵππος, *horſe*, and δρόμος, *courſe*, of the verb δρεμω, *curro*, *I run*, in *Antiquity*, a liſt, or courſe, wherein chariot and horſe-races were performed, and horſes exerciſed.

The Olympian hippodrome, or horſe-courſe, was a ſpace of ground of 600 paces long, ſurrounded with a wall, near the city Elis, and on the banks of the river Alpheus. It was uneven, and in ſome degree irregular, on account of the ſituation; in one part was a hill of moderate height, and the circuit was adorned with temples, altars, and other embelliſhments. (See Stadium.) Pauſanias (l. vi.) has given us the following account of this hippodrome, or horſe-courſe: As you paſs out of the ſtadium, by the ſeat of the Hellanodics, into the place appointed for the horſe-races, you come to the barrier (Αφεσις) where the horſes and chariots rendezvous before they enter into the courſe. This barrier, in its figure, reſembles the prow of a ſhip, with the roſtrum or beak turned towards the courſe. The other end, which joins on to the portico of Agaptus (ſo called from him who built it), is very broad. At the extremity of the roſtrum or beak, over a bar that runs acroſs the entrance (ἐπὶ κάλωνος), is placed a figure of a dolphin in braſs. (This dolphin is a ſymbol of Neptune, ſurnamed Hippian or Equeſtrian, for his having produced a horſe by ſtriking the earth with his trident, according to the fable; without the recollection of which circumſtance the reader might be ſurprized to meet with the figure of a dolphin in a horſe-courſe.) On the two ſides of the barrier, each of which is above 400 feet in length, are built ſtands or lodges, as well for the riding-horſes as the chariots, which are diſtributed by lot among the competitors in thoſe races; and before all theſe lodges is ſtretched a cable, from one end to the other, to ſerve the purpoſe of a barrier. About the middle of the prow is erected an altar, built of unburnt brick, which every Olympiad is plaiſtered over with freſh mortar; and upon the altar ſtands a brazen eagle, which ſpreads out its wings to a great length. This eagle, by means of a machine which is put in motion by the preſident of the horſe-races, is made to mount up at once to ſuch a height in the air, as to become viſible to all the ſpectators; and at the ſame time, the brazen dolphin beforementioned ſinks to the ground. Upon that ſignal the cables, ſtretched before the lodges on either ſide of the portico of

Agaptus, are firſt let looſe, and the horſes there ſtationed move out and advance till they come over againſt the lodges of thoſe who drew the ſecond lot, which are then likewiſe opened. The ſame order is obſerved by all the reſt, and in this manner they proceed through the beak or roſtrum ; before which they are drawn up in one line, or front, ready to begin the race, and make trial of the ſkill of the charioteers and fleetneſs of the horſes. (See Chariot.) On that ſide of the courſe, which is formed by a terrace raiſed with earth, and which is the largeſt of the two ſides, near to the paſſage that leads out of the courſe acroſs the terrace, ſtands an altar of a round figure, dedicated to Taraxippus, the terror of the horſes, as his name imports. The other ſide of the courſe is formed, not by a terrace of earth, but a hill of moderate height, at the end of which is erected a temple, conſecrated to Ceres Chamyne, whoſe prieſteſs has the privilege of ſeeing the Olympic games.

There is a very famous hippodrome at Conſtantinople, which was begun by Alexander Severus, and finiſhed by Conſtantine. This circus, called by the Turks *atmeidan*, is 400 paces long, and above 100 paces wide, *i. e.* geometrical paces of five feet each. Wheeler ſays it was in length about 550 ordinary paces, and in breadth about 120 ; or, allowing each pace to be five feet, 2750 feet long and 600 broad. At the entrance of the hippodrome there is a pyramidal obeliſk of granite, in one piece, about 50 feet high, terminating in a point, and charged with hieroglyphics erected on a pedeſtal of eight or ten feet above the ground. The Greek and Latin inſcriptions on its baſe ſhew that it was erected by Theodoſius ; the machines that were employed to raiſe it were repreſented upon it in baſſo relievo. See Circus.

The beauty of the hippodrome at Conſtantinople has been long ſince defaced by the rude hands of the Turkiſh conquerors ; but under the ſimilar appellation of atmeidan, it ſtill ſerves as a place of exerciſe for their horſes. Whether the Olympic hippodrome was ſo long or ſo wide as this of Conſtantinople, it is not now eaſy to determine ; but it muſt evidently have been conſiderably longer than an ordinary ſtadium, in order to allow for the turnings of the chariots and horſes round the pillars which ſerved as metas or goals, without running againſt them, or againſt one another. The length of the courſe, or the diſtance between the two metas or goals, is not eaſily aſcertained. It is probable, however, that the two pillars, *viz.* that from which the horſes ſtarted, and that round which they turned, which divided the courſe into two equal lengths, were two ſtadia diſtant from each other ; conſequently, the whole length of the race, for a chariot drawn by full aged horſes, conſiſting of 12 rounds, amounted to 48 ſtadia, or ſix Grecian miles ; and that of the chariot drawn by colts conſiſted of eight rounds or 32 ſtadia, or four Grecian miles ; a Grecian mile, according to Arbuthnot's computation, being ſomewhat more than 800 paces, whereas an Engliſh mile is equal to 1056. Pauſanias informs us, that in the Olympic hippodrome, near that pillar called Nyſſé, probably that which was erected at the lower end of the courſe, ſtood a brazen ſtatue of Hippodamia, holding in her hand a ſacred fillet or diadem, prepared to bind the head of Pelops for his victory over Oenomaus ; and it is probable that the whole ſpace between the pillars was filled with ſtatues or altars, as that in the hippodrome at Conſtantinople ſeems to have been. Here, however, ſtood the tripod, or table, on which were placed the olive-crowns and the branches of palm deſtined for the victors. Beſides the hippodromes at Olympia and Conſtantinople, there were courſes of a ſimilar kind at Carthage, Alexandria in Egypt, and other places.

We have ſome veſtiges in England of the hippodromus, in which the ancient inhabitants of this country performed their races. The moſt remarkable is that near Stone-henge, which is a long tract of ground, about 350 feet, or 200 druid cubits wide, and more than a mile and three quarters, or 6000 druid cubits in length, incloſed quite round with a bank of earth, extending directly eaſt and weſt. The goal and career are at the eaſt end. The goal is a high bank of earth, raiſed with a ſlope inwards, on which the judges are ſuppoſed to have ſat. The metæ are two tumuli, or ſmall barrows, at the weſt end of the courſe. Theſe hippodromes were called, in the language of the country, *rhedagua*, the racer *rhedagwr*, and the carriage *rheda*, from the Britiſh word *rhedeg*, *to run*. One of theſe hippodromes, about half a mile to the ſouthward of Leiceſter, retains evident traces of the old name *rhedagua*, in the corrupted one of *rawdikes*. There is another of theſe, ſays Dr. Stukeley, near Dorcheſter ; another on the banks of the river Lowther, near Penrith in Cumberland ; and another in the valley, juſt without the town of Royſton.

HIPPODROMUS, in *Chronology*, the Bœotian name for the Athenian month Hecatombæon, or Ecatombæon.

HIPPOGLOSSUM, Horse-tongue, in *Botany*, the name of a plant of the *ruſcus*, or butcher's broom kind, called by others the Alexandrian bay, or *laurus Alexandrina*.

HIPPOGLOSSUS, in *Ichthyology*, *Holibut*, a ſpecies of Pleuronectes, which ſee.

HIPPOLAPATHUM, in *Botany*, a ſpecies of lapathum, called alſo monk's rhubarb.

HIPPOLAUS, in *Ancient Geography*, a promontory of European Scythia, which was a tongue of land between the mouth of the Boryſthenes and that of Hypanis. Herodotus ſays, that here was a temple dedicated to Ceres.

HIPPOLITHOS, a name given by ſome authors to the ſtones found in the ſtomachs and inteſtines of horſes : there are often a great number of theſe in one horſe ; and they are frequently found in the colon of a very large ſize. See Bezoar.

HIPPOLYTUS, St. in *Biography*, a Chriſtian biſhop and martyr, in the third century, was the diſciple of Irenæus, and the inſtructor of Origen. He is celebrated for his zeal and labours in preaching the goſpel, and in defending the Chriſtian religion. The ſeat of his principal labours was at Rome, where it is probable he ſuffered martyrdom. This event took place in the year 230, under the emperor Alexander Severus. Some, however, aſcribe it to the perſecution under Maximinus, five years later ; and there are others who contend that it did not occur till the Decian perſecution, about the year 250. He was held in high eſtimation for his piety and learning, and he was author of a number of works on a variety of ſubjects. Of his great fame, a noble monument erected to his honour near Rome affords ſome proof. This monument conſiſts of a marble ſtatue, repreſenting a venerable perſon ſitting in a chair, on the ſides of which are engraved, in Greek letters, cycles of 16 years, forming the moſt ancient paſchal canon in exiſtence. It was publiſhed in Greek by Joſeph Scaliger, with commentaries, in 1595, and afterwards in Latin, by father Giles Bucher in 1694. Hippolytus was author of many other works ; but ſome given to him are unqueſtionably ſpurious. Dr. Lardner has inveſtigated their authenticity, and having ſo done he adds, " If I may at laſt deliver my own opinion, I would ſay, though ſcarcely any of them are altogether ſincere and uncorrupted, there are few of which ſome good uſe may not be made by a man of candour and judgment." Lardner's Credibility.

HIPPOMANE, in *Botany*, an ancient Greek name adopted by Linnæus for an American genus to which it could not poſſibly originally belong, but whoſe qualities perhaps may excuſe its application. The word is conſtructed of ἵππος, *a horſe*, and μανια, *madneſs*, the ancient plant being of ſo virulent a nature as to bring madneſs upon ſuch animals, if they happened to partake of it.—The genus in queſtion is not behind-hand with any plant in noxious qualities.—Linn. Gen. 205. Schreb. 659. Swartz. Obſ. Bot. 369. Willd. Sp. Pl. v. 4. 571. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 378. Juſſ. 391. Lamarck Illuſtr. t. 793. (Mançanilla; Plum. Nov. Gen. 50.)—Claſs and order, *Monœcia Monadelphia*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. Male-flowers in a terminal catkin. *Cal.* Perianth of one leaf, bifid, turbinate, obtuſe, very ſmall. *Cor.* None. *Stam.* A ſingle thread-ſhaped filament, twice the length of the calyx; anthers four, roundiſh, affixed croſſwiſe to the ſides of the filament towards the top. Female-flower ſolitary, terminal. *Cal.* Perianth withering, of three roundiſh, concave, obtuſe converging leaves. *Cor.* None. *Piſt.* Germen ovate, large; ſtyle very ſhort; ſtigma about ſeven-cleft, acute, reflexed. *Peric.* Drupa globular, very large, one-celled, crowned with the permanent ſtigma. *Seed.* Nut woody, irregular, acuminated, excavated with little pits and accompanied by appendages, of ſeven cells and ſeven valves; kernels ſolitary, roundiſh.

Eſſ. Ch. Male, a catkin. Perianth two-cleft. Corolla None. Female, Perianth three-cleft. Corolla None. Stigma ſeven-cleft. Drupa with a nut of ſeven cells.

1. H. *Mancinella*. Linn. Sp. Pl. 1431. Jacq. Amer. 250. t. 159. (Juglandi affinis arbor julifera lacteſcens venenata pyrifolia, Mançanilla Hiſpanis dicta; Sloan. Jam. v. 2. 3. t. 159.)—Leaves ovate, ſerrated, with one gland at the baſe; ſtalks half as long as the leaves.—Native of ſandy, watery places near the coaſt in various parts of the Weſt Indies.—This is a tall and ſpreading tree, of handſome appearance, compared by Jacquin to a Pear-tree. Every part, when wounded, exudes a plentiful, very white, but highly cauſtic and venomous milk, raiſing bliſters on the ſkin like a burn, nor can ſcarcely any part of the plant be touched with ſafety. It is reported, that many of the Europeans who firſt landed at Surinam died ſuddenly from ſleeping under this tree. Jacquin ſays, that ſome kind of Land-Crabs become poiſonous food from eating the fruit, which is by no means wonderful. The *wood*, however, is valued for being capable of taking a high poliſh, and being beautifully variegated with ſeveral dark colours. The *Leaves* are ſcattered, ovate, acute, with ſhallow ſerratures, ſmooth, veiny, about two inches long, on ſtalks not quite ſo long, which are ſlender and ſmooth, crowned where they enter the baſe of the leaf with one, round, depreſſed gland. The male *Catkins* grow at the end of the branches and are of a yellowiſh-green colour. Female-flowers at the diviſion of the twigs, ſolitary, round and green. *Fruit* the ſize of a walnut without the coat, of a yellowiſh-green, reſembling a crab-apple in ſize and ſmell; the coat is very thin, and nut large. Sloane ſays, that goats are very fond of the fruit, which does not render either their fleſh or their milk poiſonous.

It is neceſſary to obſerve, that *Hippomane biglanduloſa* of the *Plantæ Surinamenſes*, n. 129, *Amæn. Acad.* v. 8. 263, appears by the Linnæan Herbarium to be a totally different plant from that originally ſo called by Linnæus, as well as from the above deſcribed. Its leaves are like thoſe of *Magnolia grandiflora*, but we have not materials to determine its genus. Linnæus ſays, the fruit is tricoccous; if ſo, it may belong to the genus *Sapium* of Jacquin, Willd. v. 4. 572, to which the other Linnæan ſpecies of *Hippomane* are now referred. If they remain ſo, the ſpecific character of the *Mancinella* becomes ſuperfluous.

HIPPOMANES, compounded of ἵππος, *horſe*, and μανια, *madneſs*, a ſort of poiſon, famous among the ancients as an ingredient in amorous philtres, or charms.

Naturaliſts are not agreed about the nature of the hippomanes. Pliny deſcribes it as a blackiſh caruncle, found on the head of a new-foaled colt; which the dam bites off and eats as ſoon as ſhe is delivered. He adds, that if ſhe be prevented herein by any other's cutting it off before, ſhe will not take to, nor bring up her young.

Virgil, and after him Servius and Columella, deſcribe it as a poiſonous matter trickling from the pudendum of a mare, when proud, or longing for the horſe. Æn. lib. iv. ver. 515.

At the end of Mr. Bayle's Dictionary is a very learned diſſertation on the hippomanes; and all its virtues, both real and pretended.

HIPPOMYREX, the *horſe ant*, the name of a ſpecies of ant much larger and nimbler than the common kind. This builds in woods, and makes its neſts of ſticks and ſtraws, and fragments of various parts of trees. The common ant builds only with earth.

HIPPONE, in *Mythology*, the goddeſs of horſes and chariots.

HIPPONESUS, in *Ancient Geography*, a town of Aſia, in Caria.—Alſo, a town of Libya.

HIPPONIATES SINUS, a gulf of the Tyrrhenian ſea, on the weſtern coaſt of the kingdom of Naples.

HIPPONITES, a lake of Africa, on the banks of which was built the town of Hippo-Zarytus.

HIPPONIUM, called alſo *Vibo Valentia*, *Bivona*, a town of Italy, upon the weſtern coaſt of Brutium, at the lower part of a gulf, which opened to the north.

HIPPOPECTINITE, in *Natural Hiſtory*, or great ſcallop, is a foſſil ſhell, half a foot over, found in a great rock in Virginia, 40 miles from a ſea or river, according to Dr. Grew. Rarities of Greſham College, p. 262.

HIPPOPHÆ, in *Botany*, apparently from ἵππος, *a horſe*, and φαω, *to deſtroy*, a name in Dioſcorides for what he ſays was uſed by fullers in dreſſing cloths, but whoſe deſcription anſwers to ſomething of the *Rhamnus* kind. It is however in ſome points applicable to the ſhrub for which it is retained by Linnæus.—Linn. Gen. 517. Schreb. 682. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 1075. Juſſ. 75. Lamarck. Illuſtr. t. 808. Gærtn. t. 42.—(Rhamnoides; Tourn. t. 481.)—Claſs and order, *Diœcia Tetrandria*. Nat. Ord. *Calycifloræ*, Linn. *Elæagni*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of one leaf, divided almoſt to the baſe into two equal, roundiſh, obtuſe, concave, erect lobes, cohering at their ſummit, but a little gaping below. *Cor.* None. *Stam.* Filaments four, very ſhort; anthers oblong, angular, nearly equal to the calyx.

Female, *Cal.* Perianth of one leaf, ovate-oblong, tubular, ſlightly cloven at the top, deciduous. *Cor.* None. *Piſt.* Germen ſuperior, ſmall, roundiſh; ſtyle ſimple, very ſhort; ſtigma thickiſh, oblong, recurved, reaching twice the length of the calyx. *Peric.* Berry nearly globoſe, of one cell. *Seed* ſolitary, oblong, ſhining, with a furrow at each ſide, inveſted with a double membranous coat.

Eſſ. Ch. Male, Calyx in two deep ſegments. Corolla none. Female, Calyx tubular, cloven. Style one. Berry ſuperior. Seed ſolitary, doubly coated.

Obſ. Mr. Viborg, the Daniſh naturaliſt, has diſcovered ſome hermaphrodite flowers, occaſionally intermixed with the others. Gærtner deſcribes but a ſingle coat to the ſeed, which he properly calls the lining of its cell, overlooking a thicker, almoſt leathery, integument, or arillus, which cloſely enfolds the ſeed itſelf, and which is well diſplayed by Mr. Sowerby in Engl. Bot.

1. H. *rhamnoides*. Linn. Sp. Pl. 1452. Engl. Bot. t. 425. Pall. Roſſ. v. 1. t. 68. Fl. Dan. t. 265. (Rhamnus ſecundus Cluſii: Ger em. 1334.) Sallow-thorn, or Sea Buckthorn.—Leaves lanceolate.—Native of ſandy banks and marſhes near the ſea, in various parts of Europe, from the ſouth of France to Finland. It is abundant on the Norfolk coaſt, growing on the cliffs and ſand-banks, and flowering about the middle of May, nor is it unfrequently cultivated in ſhrubberies. The woody buſhy *ſtem* is ſix or eight feet high, thorny. *Leaves* ſcattered, about two inches long, lanceolate or almoſt linear, bluntiſh, entire, of a ſilvery white beneath. Both their ſurfaces, as well as the young bark and half-ripe fruit, are cloathed with minute umbilicated ſcales, as in the genus *Elæagnus*. *Flowers* ſmall, green, in the boſoms of the lowermoſt leaves of each branch, while very young, the two ſexes on different ſhrubs. *Berries* ripened in autumn, very copiouſly on the wild plants, never, as far as we have ſeen, on garden ones. They are the ſize of large currants, of a glowing orange-colour, pulpy, very acid, agreeable enough when preſerved with ſugar. Linnæus found the Finlanders uſing them as a ſauce to their fiſh, but he complained of their intolerable acidity. Rouſſeau gives a ludicrous account of the ſingular politeneſs of a young man, who ſeeing him eat theſe berries, as they were walking together, did not preſume to take the liberty of telling him they were conſidered as poiſonous.

2. H. *canadenſis*. Linn. Sp. Pl. 1453.—Canada Sea Buckthorn.—Leaves ovate.—Gathered by Kalm in Canada. It differs from the former in its much ſhorter, broader, ovate or elliptical *leaves*, very conſpicuous for their ſilvery backs, and the ruſty ſcales ſcattered over them. The *flowers* are in little, brown, ſhining, axillary cluſters.

HIPPOPHEOS. This was a name given not only to the larger ſpecies of the pheos or ſtebe, but to a very different plant, a kind of dodder, more vulgarly called epipheos, from its growing upon the pheos, as the dodder of thyme is called epithymum, from its growing upon that plant. It is poſſible indeed that it might be called originally hippopheos, from its riding, as it were, on the pheos. But however this be, there is great reaſon to ſuſpect that Dioſcorides confounds this dodder with the plant itſelf, and gives its virtues as thoſe of the proper hippopheos; which, according to Theophraſtus, and all the other writers of credit in antiquity, is only a larger ſpecies of the pheos, a prickly ſhrub, not a plant, growing on it. See Epipheos.

HIPPOPHTHALMIC Muscles, a name given by the ichthyologiſts to a pair of large muſcles found in the head of fiſh, one placed immediately under the eye; theſe ſerve to move the eyes; and, with the two maxillary muſcles placed under the jaws, are the principal muſcular parts of the head of fiſh.

HIPPOPODES, or Hippopedes, compoſed of ἵππος, *horſe*, and πους, *foot*, in *Ancient Geography*, an appellation given to a certain people ſituated on the banks of the Scythian ſea; as being ſuppoſed to have horſes' feet.

The hippopodes are mentioned by Dionyſius, Geogr. v. 310. Mela, lib. iii. cap. 6. Pliny, lib. iv. cap. 13. and St. Auguſtine, De Civit. lib. xvi. cap. 8. But the truth is, that they had this appellation given them on account of their ſwiftneſs, or lightneſs of foot.

HIPPOPOTAMUS, in *Zoology*, a genus of Mammalia in the order Belluæ; the front teeth in each jaw are four, thoſe in the upper jaw are remote and form a pair each ſide; thoſe in the lower are prominent, and the two middle ones longeſt; the tuſks are ſolitary, the lower ones long, curved, and obliquely truncated; feet furniſhed with hoofs at the margin.

Whether in reality there may exiſt more than one ſpecies of this genus appears uncertain; there is every reaſon to apprehend the morſe has been ſometimes confounded by travellers with the true hippopotamus; and the diſcordance which we trace in their reports, ariſing as it muſt be conceived from this particular cauſe, may have erroneouſly given birth to the prevailing ſuppoſition of thoſe writers who believe there are two ſpecies. The obſervations of Sonnini ſeem in favour of the exiſtence of more than one kind, yet his concluſions, however juſt, are not apparently founded on better authority than the diſcordance of writers, to which we before alluded. Thoſe who apprehend there are two ſpecies conſider one as an inhabitant of the freſh water, or rather of inland rivers, lakes, and marſhes, and the other to be entirely confined to the ſea; the latter is probably the morſe.

After the elephant and the rhinoceros, the hippopotamus has been in all ages an object of admiration to mankind; its ſize is often equal to that of the rhinoceros, and its force but little, if at all, inferior; and thus in magnitude, as well as ſtrength, it yields alone to the decided ſuperiority of the elephant.

The appearance of the hippopotamus when on the land is altogether uncouth, the body being extremely large, flat, and round, the head enormouſly large in proportion, and the legs as diſproportionately ſhort. Authors vary conſiderably in deſcribing the ſize of this animal. The length of a male has been known to be ſeventeen feet, the height ſeven feet, and the circumference fifteen; the head three feet and a half, and the girt nine feet; the mouth in width about two feet. The general colour of the hippopotamus is browniſh; the ears ſmall and pointed, and lined very thickly with fine ſhort hairs; the eyes are ſmall in proportion to the ſize of the creature, and black; the lips are very thick, broad, and beſet with a few ſcattered tufts of ſhort briſtles; the noſtrils ſmall. The armament of teeth in its mouth is truly formidable, more particularly the tuſks or canine teeth of the lower jaw, which are of a curved form, ſomewhat cylindrical, ſtriated in a longitudinal direction, and obliquely truncated at the end; theſe are ſo ſtrong and hard, that they will ſtrike fire with ſteel, are ſometimes more than two feet in length, and weigh upwards of ſix pounds each. The teeth in the upper jaw much ſmaller; thoſe in the upper jaw are of a moderate ſize; thoſe in the lower ſtrong, ſomewhat conic, ſharp pointed, and projecting forwards almoſt horizontally. The whole ſurface of the body is covered with ſhort hair, which is more ſparingly ſet on the under parts than the upper. The tail is ſhort, thick, ſlightly compreſſed, a little hairy, and marked by ſeveral ſtrong circular wrinkles. The feet are large, and each of the four lobes or toes furniſhed with a hoof.

The colour of the hippopotamus, when juſt emerging from the water, is paliſh brown, or mouſe colour, the lower parts inclining to blueiſh or ſlate colour, the belly fleſh colour, and the ſkin appearing through the hair. Sparrman ſpeaks of its "ſlimy appearance when newly come out of the water, which is ſaid to gliſten in the moon-ſhine like a fiſh," and other writers agree that the blueiſh tinge of colour that appears on the body, when riſing out of the water, is entirely diſſipated as the ſkin becomes dry.

This animal was well known to the ancients. Moſt commentators conceive it to be the behemoth of Job, who deſcribes its manners, food, and haunts ſo admirably, as to leave little reaſon for believing that ſcriptural writer alluded to any other animal. In the verſe, "Behold now Behemoth which I made near thee ; he eateth graſs as an ox." It is repreſented as an inhabitant of the Nile, in the neighbourhood of Uz, the land of Job, and as an animal that ſubſiſts on vegetable food ; the ſecond, " Lo ! now his ſtrength is in his loins, and his force is in the navel of his belly ;"—and " his bones are as ſtrong as pieces of braſs, his bones are like bars of iron," indicate its great ſtrength and the hardneſs of his bones. Its reſidence among the vaſt reedy marſhes, in rivers overſhadowed with thick foreſts, is implied in the verſe, " He lieth under the ſhady trees in the covert of the reeds and fens." And in the fifth verſe, " Behold ! he drinketh up a river ; he truſteth he can draw up Jordan into his mouth," refers to the characteriſtic wideneſs of his mouth, which is poetically deſcribed as large enough to exhauſt ſuch a ſtream as the Jordan.

By writers of antiquity, the hippopotamus is deſcribed as poſſeſſing the moſt marvellous powers of ſtrength. They alſo feigned that it vomited fire, in alluſion, no doubt, to the prodigious hardneſs of its teeth, which give fire with ſteel. Among the ancient Egyptians it was revered as a tutelary divinity ; they paid it ſacred honours, and engraved its image upon their obeliſks. But if we may credit Diodorus Siculus, they would ſometimes wage war againſt this object of their adoration, attacking it with ſpears and daggers, and after inflicting many grievous wounds, leave the poor lacerated beaſt to expire through the loſs of blood. In like manner the negroes of Congo, Angola, Elmina, and other adjacent parts of Africa, at this day regard the hippopotamus as a god, and yet they not only attack and deſtroy it, but devour its fleſh with great avidity. The hippopotamus occurs among the little figures in the caſts taken from the ancient tombs of Siberia, now at Paris, from whence it is concluded this animal was formerly known in that part of the world ; not as an inhabitant, the rigorous coldneſs of the climate forbidding that idea, but as an idol, and being there worſhipped as a divinity as well as in Egypt.

Pliny relates that Scaurus, during his ædileſhip, exhibited before the Roman people four crocodiles, and one hippopotamus, in a temporary lake prepared for the occaſion. Auguſtus alſo produced one of the latter on his triumph over Cleopatra ; and after this the figure of the hippopotamus appears on various medals of the Roman emperors. For many ages after no authentic hiſtory of this animal was obtained. The firſt among modern deſcribers who have noticed it with accuracy was Zerenghi, an Italian ſurgeon, who, about the beginning of the ſeventeenth century, printed an account of it at Naples, accompanied by a figure taken from a dried ſkin, which figure is again given in the works of Aldrovandus. Since that period the hiſtory of this animal has been more fully developed, through the zealous attention beſtowed on the ſubject by travellers, to whom an opportunity has been afforded of examining the animal in the living ſtate, and in its native regions ; and to none of whom the curious are more indebted, for ſatisfactory information in this particular, than to the ingenious Dr. Sparmann.

The vaſt ſtrength of this animal would render it one of the moſt formidable of terreſtrial quadrupeds, were its diſpoſitions ferocious ; on the contrary, it is an animal of very tranquil diſpoſitions, unleſs under circumſtances of great irritation, and then its power is really to be dreaded. Its bulk is ſo great that twelve oxen have been found neceſſary to draw one aſhore that was ſhot in a river above the Cape. The largeſt hippopotamus, among about thirty, killed by colonel Gordon, was eleven feet long ; this was a female ; the largeſt male, which always exceeds the other ſex in ſize, was eleven feet eight inches. Dr. Sparmann, however, deſcribes ſome larger ; and Mr. Bruce ſpeaks of others in lake Tzana, that were more than twenty feet long. It is aſſerted by Haſſelquiſt, that the hide alone is a load for a camel.

Theſe animals inhabit the warmer parts of the globe ; and, as in ancient times, are found in the Nile, where it flows through the fens of Upper Egypt, below which it is rarely ſeen. The lateſt inſtance on record of its appearing near the mouth of that river, was in the year 1600, when two were killed near Damietta. It abounds moſt in the rivers among the woods and deſerts of Ethiopia, and in thoſe of Africa, as the Gambia, Senegal, Zaira, reſiding equally in rivers near their fall into the ſea, and in the inland lakes from the very interior of Africa to the Cape of Good Hope. Formerly they abounded in rivers near the Cape, but are now almoſt extirpated ; and it was even found neceſſary under the Dutch government, in order to preſerve the few remaining in the Berg river, to prohibit ſhooting them without expreſs permiſſion.

From the unwieldineſs of the body and the ſhortneſs of the legs, the hippopotamus is not able to move very ſwiftly upon the land, and he then becomes timid. His pace is, however, quicker on the land than generally imagined. When purſued he takes to the water, plunges in, ſinks to the bottom, and is ſeen walking at perfect eaſe, or ſwimming with like facility, the great ſize of his belly rendering his ſpecific gravity equal to that of water. He cannot, however, continue long under water without riſing towards the ſurface to breathe ; and in the day-time he is ſo fearful of being diſcovered, that when he takes in a freſh ſupply of air, the place is hardly perceptible, for he does not venture even to put his noſe out of the water. In rivers unfrequented by mankind he is leſs cautious, and puts his whole head out of the water. If wounded, he will riſe and attack boats or canoes with great fury, and often ſink them by ſtriking, or biting large pieces out of their ſides, and thus people are frequently drowned by theſe animals. It is reported alſo that they will at once bite a man in two. In ſhallow rivers the hippopotamus makes deep holes in the bottom, in order to conceal its great bulk. When he quits the water he uſually puts out half his body at once, and ſmells and looks around, but ſometimes ruſhes out with great impetuoſity, and tramples down every thing in his way. It is hazardous to navigate canoes in rivers much infeſted by theſe animals, as the ſlighteſt movement of their bodies may eaſily overſet them.

The food of the hippopotamus is entirely of the vegetable kind, in queſt of which he quits his watery reſidence, under the favourable darkneſs of the night, and ranges in ſecurity along the banks and adjacent places, deſtroying in his progreſs, by the tramplings of his feet, an infinitely greater portion of herbage than could poſſibly be required to ſatisfy the craving of its appetite. He feeds on the roots of graſs which he readily tears up with his teeth. In cultivated places he commits incredible miſchief, eſpecially among the plantations of ſugar, rice, corn, and other grain, and among young and tender trees, the ſhoots of which he eagerly devours.

The manners of the hippopotami approach nearer to thoſe of the hog than the horſe tribe, with which its name implies an affinity ; for which reaſon Alpin calls them *Cheropotames*, or river-hogs. They commonly ſleep in the reedy iſlands, in the middle of rivers, and if poſſible in ſituations ſurrounded by thick foreſts, and deep impenetrable marſhes ; and in ſuch ſituations they bring forth their young. A herd of females is ſaid to have but one male ; they bring forth one young at a time, and that on the land, but ſuckle the young in the water. The males often conteſt each other's right over the females; and the attack of two ſuch powerful animals, as may naturally be imagined, is terrible. The earth ſhakes beneath them, the water trembles, their blood flows in torrents, and the maſſes of fleſh torn out by their mighty graſp of teeth lie ſcattered upon the blood-ſtained ſcene of conflict. Sometimes the weakeſt, perceiving his efforts ineffectual, leaves his antagoniſt maſter of the field, but this does not happen often; for it is ſeldom that one or both of them does not periſh on the ſpot. The female is ſuppoſed to go with young nine months. She is often ſeen in the rivers with the young one on her back, and her manner of ſuckling is not diſſimilar to that of the cow, the teats, which are ſmall, and two in number, being placed far back under the belly; the milk is thin and more aqueous than that of the cow. The female, at particular ſeaſons, has a ſtrong ſmell of muſk.

The modes of capture adopted in taking theſe animals are various. They are ſometimes ſhot, ſometimes attacked with harpoons, and ſometimes taken in pit-falls prepared for the occaſion in the banks of rivers. In ſome parts the natives place boards full of ſharp irons in the ground, which theſe heavy beaſts ſtriking into their feet become incapable of moving, and thus fall an eaſy prey. Sometimes they are ſtruck in the water with harpoons fixed to cords, and ten or a dozen canoes are employed in the chaſe. This is the common method in which it is taken in Africa. Haſſelquiſt tells us the Egyptians have a curious manner of relieving themſelves in ſome degree from this deſtructive animal. "They remark the places (he ſays) which he frequents moſt, and there lay a large quantity of peas; when the beaſt comes aſhore, hungry and voracious, he falls to eating what is neareſt him; and, filling his belly with the peas, they occaſion an unſupportable thirſt. He then returns immediately into the river, and drinks upon theſe dry peas large draughts of water, which ſuddenly cauſe his death; for the peas ſoon begin to ſwell with the water, and not long after the Egyptians find him dead on the ſhore, blown up as if killed by the ſtrongeſt poiſon."

The fleſh of the hippopotamus is eaten in Africa by the poorer orders of people, who, as a matter of emolument, firſt ſeparate it from the fat, a kind of fine lard with which the animal abounds, and which bears a conſiderable price, both on account of its flavour, and becauſe it is ſuppoſed to poſſeſs many admirable virtues. This animal is alſo taken for the ſake of the hide, which on the back is two inches thick or more, and which, when dried, is ſaid to be proof againſt the ſtroke of a muſket-ball. This is converted by the Africans into ſhields or bucklers. The value of the teeth is another inducement for its deſtruction; theſe, the tuſks in particular, being ſuperior in hardneſs to ivory, at the ſame time they are not ſo ſubject to become yellow, and therefore better for the purpoſe of the dentiſt: ſuperſtition has further ſtamped on them an additional value, the Africans conſidering them as an antidote to poiſon, and uſually wearing ſome trinkets formed of theſe teeth about their perſons. And finally it may be added, upon the credit of Labat, that the blood of this animal is employed by the Indian painters in the preparation of their colours, though in what manner we are not informed.

The mild diſpoſition of theſe animals is confirmed by Belon, who aſſures us that when young they are eaſily tamed. He ſaw one kept in a ſtable, and which ſhewed no inclination to eſcape, or do any kind of miſchief, when, as ſometimes happened, he was releaſed from his confinement. The cry of this animal has been variouſly deſcribed; Adanſon, an author of veracity, declares it to be ſimilar to that of the horſe, uttered with conſiderable force.

In concluſion, we ſhall notice the intereſting obſervations made on the hippopotamus by Dr. Sparrman, a writer whoſe accuracy is in general indiſputable; the ſtyle adopted by that author is rather prolix, and it beſides abounds in local incidents not immediately neceſſary to be related, but as theſe cannot eaſily be expunged without detriment to the fidelity, and tendency of the repreſentation he has given, it will be beſt to repeat the obſervations of that traveller in their varied details, in his own words.

"Towards evening, on the 24th of January 1776, we came to a pit in the river, which our guides knew uſed to be frequented by ſea-cows (meaning the hippopotami.) For this reaſon, all unfrequented ways by which theſe animals might come up from the river were beſet by us ſeparately; our hunting party conſiſting in the whole of ſeven perſons, namely, five of us Chriſtians, together with my Hottentot, and another belonging to the farmers. Beſides this, the reſt of the Hottentots were ordered to go to the windward, and to the more open places; and by ſmacking their whips, and making other noiſes, to frighten and drive the animal towards us as ſoon as it ſhould make its appearance; in conſequence of which meaſures, it appeared to us, that when at length obliged to go on ſhore in queſt of its food, it muſt neceſſarily come to the hiding-place of ſome one of the hunters. Every one of theſe places were juſt at the edge of the river between the reeds which grew on the dry parts of the river, or in thoſe ſpots which the water had left, and at the ſame time cloſe to the very narrow paths which the animal had made for itſelf at each place; in conſequence of which diſpoſition, it would inevitably paſs not above ſix inches, or a foot at moſt, from the mouth of the ſportſman's piece. Conſequently our whole dependance was upon two circumſtances, *viz.* that our guns ſhould not miſs fire, and that the ſhot ſhould not fail to prove mortal. In the former caſe, the ſportſman muſt have inevitably paid for his temerity with his life; though in the latter, he had reaſon to hope, from inſtances of what had happened to others, that the fire, together with the report from the piece, as well as the ball itſelf, would confuſe the animal, ſo as to prevent it from immediately making towards its enemy. The banks of the pit, which were then beſet, were in moſt places ſteep and perpendicular, and the pit itſelf almoſt three quarters of a mile long; but my poſt, and that of my fellow traveller, (Mr. Immelman,) happened to be at the diſtance of not above thirty or forty paces from each other. To theſe very places too, after we had waited at them an hour and a half, in the moſt profound ſilence, the enormous animals did not fail to reſort. They had already, while on the other ſide of the river, got ſcent of the Hottentots, and now ſhewed, by their ſwimming up and down, and blowing themſelves, as well as by a ſhort but acute and piercing grunt or neighing noiſe, that they had a great ſuſpicion of the paſſes: I believe Mr. Immelman was not leſs eager and anxious than myſelf, each of us expecting at every moment to have a bout with a large enormous beaſt, which we knew had given certain proofs of its being able to bite a man aſunder. Yet were we each of us at times no leſs fearful leſt the other ſhould have the honour of killing game of ſuch conſequence. The hippopotamus, however, left us, and had made its appearance in the ſame manner, where the farmers were ſtationed; notwithſtanding which at that very inſtant we heard it ſhot at by one of the Hottentots.

"The ſable darkneſs of the night, and the glittering of the Hottentot's piece, together with the loudneſs of the report from it, occaſioned by the weight of the charge, and the vibrations of the echo prolonging the ſound along the neighbouring chain of mountains, all conſpired to compoſe a moſt awful and ſuperb ſpectacle, which was ſtill heightened by the expectation of ſeeing an animal fall, ſuperior in bulk to the elephant. This ſublime ſpectacle was immediately followed by a ridiculous kind of farce performed by a troop of baboons, which, from their calling and anſwering each other along a ſtraight line, we could diſcover to be encamped on a ſteep rocky mountain in the neighbourhood, with regular outpoſts in the trees on each ſide of it. After an interval of a couple of minutes, ſilence again took place, till two o'clock, when the other Hottentot fired his piece; and another alarm, though of ſhorter duration, went through the baboons' outpoſts and head-quarters.

"The next morning, for the arrival of which we ardently longed, in order to ſatisfy our curioſity, our Hottentot ſportſmen related to us the following particulars concerning the adventures of the night. Involved in darkneſs, covered up to the eyes in reeds, and overſhadowed with branches of trees, they could only get a glimpſe of the animal, and conſequently could not anſwer for their ſhots having taken place, and one of them acknowledged, that he was a little confuſed, as he could not well ſee what he was about, and for the ſame reaſon fired his piece too ſoon, before the animal had well riſen out of the water. The other indeed had had an opportunity, both with the ball and ſhot that made up the charge, of wounding the animal which went on its road and paſſed directly by him; but he could not ſee which part of the animal preſented itſelf before the muzzle of his piece. As ſoon as he had fired he ſlank away, and directly afterwards heard the beaſt take to the water. The reſt of the Hottentots had obſerved one of theſe animals, probably a different one from this, run up on a ſhallow along the river ſide, and thus make its eſcape, without having been able to prevent it. After this we ſtaid here till the afternoon, in hopes that the wounded animals would die, and riſe to the top of the water. But we ſtaid in vain, and to as little purpoſe would it probably have been had we waited longer, as there grew by the ſide of the river a great number of trees, to the roots of which theſe creatures, it is ſaid, in the agonies of death make themſelves faſt by means of their long and crooked tuſks. On the other hand, ſuppoſing thoſe two ſea-cows to be but ſlightly wounded, they would be cautious how they made their appearance, and indeed, in all probability, it would have been a dangerous ſervice to the ſportſman who would have ventured to have followed them any farther. Beſides, the water had now, in the ſpace of a few hours, riſen conſiderably, and had overflowed many ſpots fit for lying in ambuſh; for which reaſon we departed to another hippopotamus pit, leſs than this. Here, too, we laid, by way of ſnare, a large blunderbuſs. The Hottentots occupied one poſt; two of our companions guarded another; other two (an old farmer and his ſon) ſtationed themſelves at the third, and placed me in the middle of them. Juſt in this part the banks of the river were of a conſiderable height, and the river itſelf was dried up near an extenſive ſhallow, where it was ſpread out into a little plain covered with pebble ſtones and gravel. We three then ſet ourſelves down cloſe by the ſide of each other, in a path made by the ſea-cows, making ourſelves pretty certain, as the place was flat, and conſequently it was light here, of being able, if any hippopotamus ſhould chance to come upon the ſhallow and look about it, to ſee it plain enough to kill it with a volley of three ſhots. But to the great endangering of our lives, we on a ſudden found the animal much quicker in its motions as well as bolder than we had thought it; for while I was ſitting half aſleep and moralizing on the ſubject, ſtruck with the conſideration that we with our guns had at that preſent moment the dominion over Job's leviathan or behemoth; while on the other hand the flies or ſmall muſquitoes had the dominion over us, (ſo much indeed, that I was obliged to wrap my face up in a handkerchief,) a ſea-cow came ruſhing towards us out of the river with a hideous cry, as ſwift as an arrow out of a bow, at the ſame time I heard the farmer call out "Heer Jeſus!" But fortunately, at the very inſtant he diſcharged his piece, which flaſhing full in the animal's face, contributed perhaps more than the ball to make it ſtart back; when ſetting up another cry, it threw itſelf into the water again with as great precipitation as it came out.

"At this I was not a little alarmed, yet, what is very ſingular, not at the danger, which was real, of being trampled under foot, or being bitten aſunder by the beaſt, but in conſequence of my apprehenſions, which were merely imaginary, of being drowned; for the rattling noiſe ariſing from the creatures running out of the water, and along the ſtony beach, immediately ſuggeſted to me the idea that the river had on a ſudden overflowed its banks; a ſuppoſition to which I was the more inclined, as I knew that this accident very frequently happens here. And as to the hippopotamus, when it is newly come out of the water, and is wet and ſlimy, it is ſaid to gliſten in the moon-ſhine like a fiſh, it is no wonder that as ſoon as I took my handkerchief from before my eyes, it ſhould appear to me at ſo near a view as I had of it, like a high column of water, which ſeemed to threaten to carry us off and drown us in a moment; for which reaſon I ran, or rather flew towards the higher ground, leaving both my guns and my brother centinels behind me. But as juſt at this ſpot I was prevented by the ſteepneſs of the river's banks from aſcending the heights, and nevertheleſs perceived that neither my companions nor myſelf were drowned, it ran in my head, for the ſpace of ſeveral ſeconds, that we were all of us dreaming, or elſe delirious. The farmer's ſon had fallen aſleep, and ſtill continued to ſleep very ſoundly. As to the farmer himſelf, who, panting and breathleſs, every now and then looked up to heaven, and at the ſame time with much aukwardneſs and buſtle was endeavouring to make his eſcape. I made all the haſte I could to diſengage him from a large wrapper, which, as well on account of his gout as by way of keeping off the flies, he had wrapped round his legs. I then aſked him what courſe the water had taken when it overflowed? and he, after a long pauſe, anſwered only by aſking me, in his turn, if I was not mad? Upon which I was almoſt ready to put the ſame queſtion to myſelf. And even at laſt, when all this was unriddled to me, I could not help doubting the truth of it, till I found the farmer's gun was really diſcharged; for the rattling among the ſtones, and the ſquaſhing in the water occaſioned by the ſea-cow, was what I firſt heard, and what made me take to my legs; ſo that I did not in the leaſt attend either to the report of the gun or the cry of the animal, though theſe latter appeared to the reſt of our party the moſt terrible; ſo much indeed, that they occaſioned Mr. Immelman, together with the farmer's ſon-in-law, to fly from their poſt, though they had ſeen nothing of all that had happened, and could not eaſily have come to any harm."

"On the twenty-fifth, from ſome traces of the ſea cows which we found in the duſt near another ſpot, we concluded that many of theſe huge amphibious animals had lately taken up their quarters in a certain pit thereabouts; which we accordingly prepared to lay ſiege to in every poſſible way. In the mean time, we ſaw a young lion make its eſcape into a cloſe thicket on the ſide of this ſame pit, where it might be perfectly ſafe from us and our hounds. Not much approving of this animal's being ſo near a neighbour to us, we thought it beſt for ſeveral of us markſmen to be together at each hiding place; at the ſame time ordering our Hottentots, partly by making a noiſe and uproar, and partly by the means of making large fires, to frighten the ſea-cows from attempting any of the other paſſes. Theſe animals had probably been beſet in the ſame manner ſeveral times before, as this night we ſcarcely heard any thing of them. In the mean while, however, we flattered ourſelves, that by continuing to block them up, we ſhould, at leaſt, by ſtarving them, force them to quit their aſylum, and expoſe themſelves on the land, to the fire of our guns.

"On the following day we were likewiſe on the look out after theſe animals, between the hours of ten and eleven in the forenoon, and alſo juſt before duſk, though upon quite a different plan from what we had before, as we meant now to hit them on their ſnouts the inſtant they ſhould ſtick them up within the reach of our guns out of the water in order to take breath, or more properly (as it is not inaptly called by the coloniſts,) to blow themſelves. In order that the ſhot might prove mortal, we were obliged, however, on this occaſion, to direct it in ſuch a manner, that the ball ſhould paſs through the cavity of the noſe into the brain. It was merely upon this plan that we went out after the ſea-cows before we arrived at Agter Bruntjeſhoogte, and were ſtrengthened by the farmer's party. But we conſtantly found theſe animals too ſhy to allow us to put our deſigns in execution; for although, in thoſe places where they had not been frightened or wounded, they will often, in the middle of the day, raiſe their heads and part of their bodies above the ſurface of the water, they at this time ſcarcely ventured juſt to put out one of their noſtrils, in order to breath almoſt imperceptibly; and this only for the moſt part in thoſe ſpots in which they were ſheltered from us by the hanging branches of trees. Notwithſtanding this diſadvantageous ſituation, they, in conſequence of the acuteneſs of their ſmell, ſeemed ſtill to diſcern us, eſpecially when we were to the windward of them; as in that caſe they inſtantly withdrew to another part." "The ſame night we betook ourſelves again to our poſts, and at half an hour paſt eight, it being already very dark, a ſea-cow began at intervals to put its head up above the water, and utter a ſharp, piercing, and as it were, a very angry cry, which ſeemed to be between grunting and neighing. Perhaps this cry may be beſt expreſſed by the words *heurkh hurkh huh-huh*; the two firſt being uttered ſlowly, in a hoarſe, but ſharp and tremulous ſound, reſembling the grunting of other animals; while the third, or compound word, is ſounded extremely quick, and is not unlike the neighing of a horſe. It is true, it is impoſſible to expreſs theſe inarticulate ſounds in writing; but perhaps one may make nearer approaches to it than one can to the gutturo-palatal ſounds of the Hottentot language. At eleven o'clock came the ſame, or elſe ſome other hippopotamus, and, in like manner, viſited the poſts we occupied. He did not, however, dare to come up, though, to our extreme mortification, we heard him come and nibble the boughs which hung over the ſurface of the water, as well as a little graſs, and a few low ſhrubs which grew here and there on the inſide of the river's banks. We were, however, in hopes that this way of living would not long ſuffice animals, one of which only required almoſt a larger portion than a whole team of oxen. Thus far, at leaſt, is certain, that if any one ſhould calculate the conſumption of proviſions made by a ſea-cow from the ſize of its fauces, and from that of its body and his belly, which hangs almoſt down to the ground, together with the quantity of graſs."

"We paſſed the following night at the ſame poſts as we occupied on the night preceding, the ſea-cows acting much in the ſame manner as before. On the 28th after ſun riſe, juſt as we were thinking of going from our poſts home to our waggons, there came a female hippopotamus with her calf from ſome other pit or river, to take up her quarters in that which we were blockading. While ſhe was waiting at a rather ſteep part of the river's banks, and looking back after her calf, which was lame, and conſequently came on but ſlowly, ſhe received a ſhot in her ſide, upon which ſhe directly plunged into the water, but was not mortally wounded; for Flip, (the farmer's ſon,) the drowſieſt of all ſublunary beings, who had ſhot her, and that inſtant could hardly be awakened by two Hottentots, was ſtill half aſleep when he fired his piece. And happy was it for him that the enormous beaſt did not make towards his hiding, or rather ſleeping place, and ſend him into the other world to ſleep for ever. In the mean while his ſhot was ſo far of ſervice, that one of my Hottentots ventured to ſeize the calf, and held it faſt by its hind legs, till the reſt of the hunting party came to his aſſiſtance. Upon which the calf was bound faſt, and with the greateſt joy borne in triumph to our waggons; though while they were taking it over a ſhallow near the river, the Hottentots were very much alarmed, leſt the wounded mother and the other ſea-cows ſhould be induced, by the cries of the calf, to come to its reſcue; the creature, as long as it was bound, making a noiſe a good deal like a hog that is going to be killed, or has got faſt between two poſts. The ſound, however, proceeding from the hippopotamus calf was more ſhrill and harſh. It ſhewed likewiſe a conſiderable ſhare of ſtrength in the attempt it made to get looſe, and was found to be quite unmanageable and unwieldy; the length of it being three feet and a half, and the height two feet; though the Hottentots ſuppoſed it to be no more than a fortnight, or at moſt, three weeks old. When at laſt it was turned looſe, it ceaſed crying; and when the Hottentots had paſſed their hands ſeveral times over its noſe, in order to accuſtom it to their effluvia, began directly to take to them." "While the calf was yet alive, I made a drawing of it, a copy of which may be ſeen in the Swediſh Tranſactions for 1778. After this, it was killed, diſſected, and eaten up in leſs than three hours time. The reaſon of this quick diſpatch was partly the warmth of the weather, and partly our being in abſolute want of any other freſh proviſions. We found the fleſh and fat of this calf as flabby as one might have expected from its want of age, and conſequently not near ſo good as that of the old ſea-cows; of which I found the fleſh tender, and the fat of a taſte like marrow, or at leaſt not ſo greaſy and ſtrong as other fat. It is for this reaſon the coloniſts look upon the fleſh and fat of the ſea-cow as the wholeſomeſt meat that can be eaten; the gelatinous part of the feet in particular, when properly dreſſed, being accounted a great delicacy. The dried tongues of theſe animals is conſidered, even at the Cape, as a rare and ſavoury diſh. On my return to Sweden, I had the honour to furniſh his majeſty's table with a dried ſea-cow's tongue, two feet eight inches long. With reſpect to form, the tongue of a full grown hippopotamus is very blunt at the tip, and is in fact broadeſt at that part; if, at the ſame time, it is ſlanted off at one ſide, and marked with many lobes, as I was informed it is, this circumſtance may, perhaps, proceed from the friction it ſuffers againſt the teeth, towards the ſide on which the animal chiefly chews; at leaſt, ſome traces of this oblique form were diſcoverable on the dried tongue I am ſpeaking of."

The food of the hippopotamus, according to Dr. Sparrman, conſiſts entirely of herbs and graſs, a circumſtance, he remarks, of which we are informed by father Lobo, and which may partly be inferred from the figure of the ſtomach. Hence this writer thinks it very improbable the hippopotamus

mus ſhould ever hunt after fiſh, as is aſſerted by Buffon and Dampier; and this the more eſpecially, as in ſome of the rivers in the ſouthern parts of Africa, where the ſea-cows are daily ſeen in great abundance, there is no fiſh; and in others which they inhabit, only a few "baſtard ſpringers" (cyprinus gonorynchus), which are ſcarcely larger than the common herring. "It is true, (ſays Dr. Sparrman,) that the ſea-cows ſometimes frequent the mouths of the rivers here, which are full of ſea-fiſh, and even ſometimes the ſea itſelf: we know, however, that theſe huge quadrupeds are, notwithſtanding this, obliged to go from thence upon dry land in queſt of food. Neither is it probable that they can drink ſea-water, as an inſtance was related to me of the contrary in a hippopotamus, which having taken refuge in the ſea, and yet was obliged to go aſhore every night, and drink freſh water from a well in the neighbourhood, till at laſt it was ſhot by ſome people that lay in wait for it there. That the hippopotamuſes actually lived in ſalt water, I have ſeen evident proofs at the mouths both of the Kromme and Camtour rivers, particularly the latter, on my journey homewards; where many of theſe animals blowed themſelves in broad day-light, and thruſt their heads up above the water; and one of them in particular, which had been wounded by an ill-directed ſhot on the noſe, neighed from anger and reſentment. In Krakekamma, I ſaw on the beach manifeſt traces of an hippopotamus, which had come out of the ſea, but had retired thither again directly. That very attentive navigator Capt. Burtz informed me, that he had frequently ſeen, on the eaſtern coaſt of Africa, ſea-horſes (meaning probably the hippopotamus) raiſe their heads above the ſurface of the water, in order to blow themſelves and neigh. I have been induced to be rather circumſtantial on this ſubject, as M. Adanſon had taken it into his head, in his "Voyage au Senegal," to limit the abode of the hippopotamus to the freſh-water rivers only in Africa; and M. de Buffon has taken upon him to ſupport this opinion, and to render Kolbe's teſtimony to the contrary liable to ſuſpicion.

"The method of catching the hippopotamus conſiſts (beſides ſhooting it) in making pits for it in thoſe parts which the animal paſſes in its way to and from the river; but this method is peculiar to the Hottentots, and is only practiſed by them in the rainy ſeaſon, as the ground in ſummer is too hard for that purpoſe. It is ſaid that they have never ſucceeded in killing this huge aquatic animal with poiſoned darts, though this mode of killing game is practiſed with advantage by the Hottentots, for the deſtruction both of the elephant and rhinoceros. The coloniſts, likewiſe, were not entirely unacquainted with the method mentioned by M. Haſſelquiſt, as being common in Egypt, *viz.* to ſtrew on the ground as many peas or beans as the animals can poſſibly eat, by which means it burſts its belly and dies. But as this method is very expenſive, and they can generally have this animal for a ſingle charge of powder, and a tin ball, ſhot in a proper direction, they chiefly, and almoſt entirely have recourſe to this cheaper expedient."

Not on his own authority, but on the aſſurance of old experienced hunters, Dr. Sparrman tells us the hippopotamuſes couple in the ſame manner as the common cattle. A brother ſportſman, ſaid he, once obſerved a peculiar kind of vermin on the body of an hippopotamus. Theſe amphibious animals are likewiſe much infeſted with inteſtinal worms, one of which, found on the calf before-mentioned by Dr. Sparrman, he deſcribes as being a kind of leech of about an inch long, the colour blackiſh, with a browniſh line down the back, and the lower ſurface pale brown. With regard to its food, this writer imagines the adult animal may be not very choice, as the calf, apparently preſſed by hunger, was obſerved to eat the dung of one of the oxen belonging to their party.

"Having already (ſays Dr. Sparrman) exceeded the limits I had preſcribed to myſelf, I do not intend to dwell here on the anatomy of the hippopotamus we caught, particularly as the internal conformation of the calves is ſomewhat different from that of the adult animal. I ſhall, therefore, only briefly mention the following particulars: the ſtomachs were four in number, and conſequently one more than in the fœtus examined by M. Daubenton, which was kept in ſpirits. The two firſt ſtomachs were each of them about ſeven inches long, and three inches in diameter; the third nine inches in length, and a little wider than the two former; the fourth was ſeven inches long, and at the upper part five inches broad, but decreaſed by degrees on one ſide till it terminated in the *pylorus*, which had an aperture an inch wide, being about half as wide again as the *cardia*. I did not obſerve any ſuch valves as M. Daubenton has delineated. The firſt ſtomach we found moſtly empty, it containing only a few lumps of cheeſe and curd: it likewiſe differed from the reſt by the ſuperior fineneſs of its internal coat. The internal membrane of the ſecond ſtomach was rather coarſer, and had many ſmall holes in it; it likewiſe contained ſeveral clods of caſeous matter, together with a great quantity of ſand and mud. The third ſtomach had very viſible folds, both longitudinal and tranſverſe, on the inſide of it, and contained caſeous lumps of a yellow colour, and harder conſiſtence than the others, together with ſeveral leaves quite whole and freſh, and at the ſame time ſome dirt. The interior membrane of the fourth ſtomach was very ſmooth, though it was not without folds: in the ſtomach itſelf there was a good deal of dirt, with a ſmall quantity of curds, which were whiter than they were in any of the other ſtomachs. The fourth ſtomach in a great meaſure covered the reſt, being ſituated on the right ſide of the animal, and was found to have the upper part of the melt adhering to its ſuperior and interior edge. This latter viſcus, which was one foot long and three inches broad, diverged from it downwards on the left ſide. The inteſtinal canal was 109 feet long; the liver meaſured fourteen inches from right to left, and ſeven or eight from the hind to the fore-part; on its anterior edges it had a large notch, being in other reſpects undivided and entire; it was of an oblique form, being broadeſt towards the left ſide, where I diſcovered a gall-bladder five inches in length. In the uterus there was nothing particular worthy of obſervation. I found two teats, and the heart ſurrounded with much fat; the length of this muſcle was five inches, and the breadth about four inches and a half. The communication between the auricles, called the *foramen ovale*, was above an inch in diameter. Each lung was eleven inches long and undivided: but at the ſuperior and exterior part of the right lung, there were two globules or proceſſes, elevated half an inch above the ſurface; and on the ſide correſponding to it, in the left lung, and in the upper part of it, there was a little excreſcence terminating in a point: ſomewhat below this, yet more forwards, there was found likewiſe a proceſs half an inch in height. Directly over the lower part of the communication formed between the right and the left lung, there was a kind of creſt or comb, meaſuring an inch from the top to the baſis."

HIPPOPOTAMUS *Foſſil.* Zoologiſts are acquainted with one living ſpecies of hippopotamus only; but late obſervations have proved that the bowels of the earth contain the foſſil remains of *two* perfectly diſtinct ſpecies, one of which appears not to differ in any reſpect from the one ſtill exiſting; the other, being, as it were, a miniature copy of the larger, is nearly of the ſize of the wild boar. The diſcovery of this latter we owe to the indefatigable Cuvier, who has likewiſe proved the exiſtence of the other ſpecies in a foſſil ſtate. Several authors, prior to that celebrated naturaliſt, have mentioned foſſil bones of the great African hippopotamus, but ſubſequent obſervations have proved that they had been rather too raſh in forming their diagnoſis. Some of the teeth deſcribed by Daubenton as the *molares* of the hippopotamus, are proved by Cuvier to be thoſe of the maſtodonte, or the great American animal improperly called mammouth. Peter Camper, who has given an account of foſſil teeth of the hippopotamus, appears to have fallen into the ſame error as Daubenton. Merk likewiſe deſcribes a tooth of a hippopotamus found in the neighbourhood of Frankfort on the Mayn, which turns out to be a worn out intermediate tooth belonging to the ſame American animal. The tooth of a hippopotamus, mentioned by Deluc as having been found among the volcanic productions in the vicinity of Frankfort, is, according to Merk, nothing but the tooth of a rhinoceros. The teeth which Lang has figured under the ſame name are probably thoſe of a horſe, partly undeveloped, partly worn off. Alſo, Romé de l'Iſle, de Lametherie, and Faujas St. Fond were led into error with regard to the teeth they deſcribed as belonging to the river horſe. Some writers, on the other hand, have been in the poſſeſſion of real foſſil remains of the hippopotamus without being aware of it. Thus Aldrovandus has figured ſeveral *molares* of this animal under the name of elephant's teeth, while the real elephant's tooth, of which he has likewiſe given a repreſentation, was conſidered by him as belonging to ſome large unknown animal. The only authors who have been more correct, both in the application of the name of hippopotamus, and in their obſervations reſpecting the foſſil remains of the animal in queſtion, are Antoine de Juſſieu and Daubenton: the foſſil bones deſcribed by the former as early as 1724, cannot be doubted to be really thoſe of the river horſe; and thoſe indicated by Daubenton under the ſame name, and depoſited (promiſcuouſly with others, which, as above-mentioned, belong to the maſtodonte) in the muſeum at Paris, were the firſt that ſerved to convince Cuvier of the exiſtence of foſſil remains of

1. *The great or common Hippopotamus.*—One of the laſt-mentioned ſpecimens of oſſeous remains conſiſts in a portion of the right ſide of the lower jaw containing two molar teeth; the other in a ſingle molar tooth. The place where they were found is not known with certainty. A third ſpecimen, examined by Cuvier, is a fragment of the upper jaw, with two molar teeth, in the collection of M. de Drée; it is penetrated by a ferruginous ſubſtance, but does not bear any indication of its origin; it is not, however, improbable that it was found in the neighbourhood of Montpellier.

More ſatisfactory than the preceding ſpecimens, with regard to its locality, was one in the collection of M. Miot. This bone, which was known to have been gathered in the Val d'Arno, in Tuſcany, is an aſtragalus, reſembling that of a hog, to which animal the hippopotamus approaches more than to any other, with regard to the conformation of all its parts. The place where bones of the hippopotamus are actually found being thus aſcertained, Cuvier applied to Fabbroni at Florence, who ſent him drawings of two molar teeth, and one repreſenting a fragment of a tuſk or canine tooth, which Cuvier ſoon aſcertained to belong to the animal in queſtion. Reſpecting the canine tooth, it is obſerved by Fabbroni, that it differs from that of the African hippopotamus in its diameter being greater compared with its length, and alſo in its ſpiral curvature being much more diſtinct. He adds, that theſe teeth are ſcattered in various parts of the upper valley of Arno, but unaccompanied either by jaws or other bones.

Cuvier thinks there is no material difference either between theſe foſſil teeth or the aſtragulus he has examined, and thoſe of the living ſpecies; and, indeed, it is remarkable, that the animal, whoſe exiſtence in a foſſil ſtate had at firſt appeared doubtful to geologiſts, ſhould be one whoſe foſſil remains far more ſtrikingly reſemble the bones of the ſtill exiſting ſpecies, than is the caſe with any other foſſil remains which naturaliſts have referred to living animals, ſuch as the elephant, the rhinoceros, &c.

2. *The ſmall foſſil Hippopotamus.*—The maſs out of which Cuvier extracted the remains of this ſpecies, (but the geological relation of which is unfortunately unknown,) reſembles the oſſeous breccia of Gibraltar, Dalmatia, and Cette, except that the matrix, inſtead of being calcareous and ſtalactitical, is a homogeneous ſand-ſtone, which uniformly fills up all the intervals between the bones; the bones alſo form a far more conſiderable portion of the maſs than is the caſe in the Gibraltar rock. After having performed the difficult operation of diſengaging all the ſeparate oſſeous fragments, M. Cuvier found that they belonged to an animal, of which no traces had hitherto been diſcovered, but which was unqueſtionably a congener of the common hippopotamus. The teeth were found to agree in all eſſential points with thoſe of the other ſpecies; and the remainder of the oſſeous fragments which were next examined, confirmed, without a ſingle exception, what had been indicated by the characters of the teeth.

For a detailed deſcription, together with the repreſentation of the foſſil bones of both theſe ſpecies of hippopotamus, we refer to Cuvier's Memoir, in vol. v. of the Annales du Muſeum National d'Hiſtoire Naturelle.

HIPPOSIS, in the *Writings of the Ancient Phyſicians*, ſignifies a reducing any part of the body into its natural ſituation, by means of compreſſion.

HIPPOTAURUS, in *Natural Hiſtory*, the name given by authors to a creature generated between a bull and a mare. It ſeems a very unnatural copulation; but Wagner, in his Hiſtory of Switzerland, aſſures us, that the creature produced by it is ſometimes found wild in the mountainous parts of that country.

HIPPURIS, in *Botany*, is a name adopted by Linnæus from the ancients, in preference to ſome that had been given to this ſame genus by Vaillant and Dillenius. The original ἵππουρις of Dioſcorides is evidently, from his deſcription of both ſpecies, an *Equiſetum*, (ſee that article.) The preſent plant has great affinity to that genus in habit and place of growth, though differing materially in its generic characters. Its name is compounded of ἵππος, *a horſe*, and ουρα, *a tail.* Mr. Curtis has remarked that "*Hippuris* of Linnæus is Πολυγονον θῆλυ, *Polygonum fæmina*, of Dioſcorides, arranged by his commentator Matthiolus with our *Polygonum aviculare*, and *Herniaria.* Succeeding botaniſts, imagining, from the growth of its leaves, or from its producing ſeed, that it had better pretenſions to be ranked with the *Equiſetum*, abſurdly enough called it *Cauda equina fæmina*, to which Mr. Hudſon could not well avoid giving the Engliſh name of Mare's-tail." This genus was denominated *Limnopeuce* by Vaillant and Haller, and *Pinaſtella* by Dillenius.—Linn. Gen. 5.

Schreb. 8. Willd. Sp. Pl. v. 1. 26. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 4. Ait. Hort. Kew. ed. 2. v. 1. 12. Juſſ. 18. Lamarck Illuſtr. t. 5. Gærtn. t. 84.—Claſs and order, *Monandria Monogynia.* Nat. Ord. *Inundatæ*, Linn. *Naiades*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, obſolete, undivided, or ſlightly two-lobed. *Cor.* none. *Stam.* Filament one, erect, inſerted on the top of the germen; anther roundiſh, two-lobed, compreſſed. *Piſt.* Germen oblong; ſtyle awl-ſhaped, erect, longer than the ſtamen; ſtigma ſimple, acute. *Peric.* none. *Seed* only one, roundiſh, naked, rather bony, covered with a thin ſort of membrane.

Eſſ. Ch. Calyx obſolete, undivided. Corolla none. Stigma ſimple. Seed one, inferior.

1. H. *vulgaris*, Mare's-tail.—Linn. Sp. Pl. 6. Engl. Bot. t. 763. Curt. Lond. Faſc. 4. t. 1.—"Leaves whorled, numerous, linear."—A common inhabitant of ditches, pools, and ſtreams which are not very rapid, in Norfolk and the neighbourhood of London, flowering abundantly in May and June. In other parts of England it is of rarer occurrence, ſeeming to delight in a gravelly ſoil.—*Root* conſiſting of long verticillate fibres. *Stem* entirely ſimple, round, of a reddiſh tinge, and cloſely ſet with whorls of linear, entire, ſmooth leaves, about eight or more in a whorl. *Flowers* axillary, ſeſſile, and of very ſimple ſtructure, for "they conſiſt of only an oval germen, crowned with an almoſt imperceptible margin or calyx, without a corolla, and terminating in a ſimple, thread-ſhaped, pointed ſtyle, by whoſe ſide ſtands one ſimple ſtamen with a two-lobed anther. The germen becomes a ſingle naked ſeed."

2. H. *tetraphylla.* Linn. Suppl. 81. (H. lanceolata; Retz. Obſ. faſc. 3. 7. t. 1. H. maritima; Hellen. Diſſ. t. 1. Retz. Prod. 2.)—Leaves four or five in a whorl, elliptical, obtuſe. This was ſent to Linnæus by profeſſor Leche of Abo, in Finland, in which neighbourhood it is ſaid to have been firſt diſcovered by a Mr. Schulſen. It is remarkable that Pallas ſent it from Kamtſchatka as a new *Elatine*, enquiring of Linnæus if it were diſtinct from the *Alſinaſtrum*, though his ſpecimens moſt evidently diſplay the flowers of an *Hippuris*, with their ſtamen and ſtyle in full perfection. This has the habit of the ſpecies juſt deſcribed, differing only in the fewneſs of leaves in each whorl, and their broad, elliptical ſhape. Whether it has in winter any difference of appearance in foliage, like the former, whoſe immerſed leaves at that ſeaſon are peculiarly elongated and pellucid, we have no information. Retzius, in his faſciculus above quoted, contends that this genus is gynandrous.

Hippuris, in *Ancient Geography*, an iſland of the Archipelago, being one of the Cyclades.

HIPPURISCUS, an iſland of Aſia, on the coaſt of Caria.

HIPPURITES, in *Natural Hiſtory*, a name given by ſome writers to a ſtone which they fancy to repreſent a ſaddle. It is deſcribed to be a ſoft argillaceous ſtone, owing its figure of a ſaddle to certain depreſſions. This is only a luſus naturæ, and is of the nature of the hand-ſtones, and foot-ſtones, with ſeveral others, which fancy has aſſiſted in their reſemblances, but which have been very improperly called by particular names.

Hippurites is alſo a name which Dr. Grew applies to a foſſil plant of a ſtony texture, conſiſting of three ſtalks elegantly figured, to reſemble the equiſetum or horſe-tail plant. Rarities, p. 268.

HIPPURUS, in *Ichthyology*, a ſpecies of Coryphæna, which ſee.

HIPPUS, in *Medicine*, a diſorder of the eyes, wherein they continually ſhake and tremble, and thus repreſented objects as if continually fluctuating.

It is thus called from the Greek ἵππος, *horſe*; becauſe, according to Blanchard, objects appear to ſhift in it, as much as when we are riding.

HIR, in *Geography*, a town of Perſia, in the province of Kerman; 18 miles S. of Sirgian.

HIRA, a word uſed by the writers in medicine either for the inteſtinum jejunum, or for all the inteſtines, or in a yet larger ſenſe for all the contents of the abdomen. Caſtel. Lex. in voc.

Hira, or *Alexandria*, *Meſjid-ali* or *Meham-ali*, in *Ancient Geography*, a town of Aſia, near a lake, at ſome diſtance from the right bank of the Euphrates: the reſidence of a dynaſty of princes, who ſerved the Perſians and Parthians againſt the Romans.

HIRABAD, in *Geography*, a town of Perſia, in the province of Irak. N. lat. 32° 16′. E. long. 55° 50′.

HIRÆA, in *Botany*, ſo called by Jacquin after John Nicholas de la Hire, a French phyſiological writer in the Memoires de l'Acad. des Sciences, whoſe remarks are ſometimes cited by Du Hamel and others; and who diſcovered an exudation reſembling manna on the leaves of orange-trees.—Jacq. Amer. 137. Linn. Syſt. Veg. ed. 14. 427. Schreb. 307, 804. Willd. Sp. Pl. v. 2. 743. Mart. Mill. Dict. v. 2. (Flabellaria; Cavan. Diſſ. 436. Triopteris Hiræa; Gærtn. t. 116.)—Claſs and order, *Decandria Trigynia.* Nat. Ord. *Trihilatæ*, Linn. *Malpighiæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ſmall, erect, in five deep ſegments, permanent, without any nectariferous external glands. *Cor.* Petals five, roundiſh, concave, widely ſpreading, with long linear claws. *Stam.* Filaments ten, awl-ſhaped, erect, ſlightly connected at the baſe, five of them alternately ſhorter; anthers erect. *Piſt.* Germens three, ſuperior, ovate, connected; ſtyles awl-ſhaped, erect; ſtigmas capitate or cloven. *Peric.* Capſules three, roundiſh, not burſting, with two very large, tranſverſe, rounded wings, ſometimes united, and a ſmaller longitudinal central one. *Seeds* ſolitary, ovate.

Eſſ. Ch. Calyx in five deep ſegments, without any honey-pores. Petals roundiſh, with claws. Filaments connected at the baſe. Capſules three, cloſed, ſingle-ſeeded, with two or three unequal wings.

Obſ. This genus has been confounded with *Triopteris*, and it is doubtful whether they ought not to be united, according to the ſentiments of Gærtner and Juſſieu. The chief difference lies in the two nectariferous glands or pores, ſaid to diſtinguiſh the calyx of *Triopteris*, and its narrower, more vertical, and more divided wings.

1. H. *reclinata.* Jacq. Amer. 137. t. 176. f. 42. Gærtn. t. 116. Linn. Mant. 240.—Leaves obovate, blunt at each end, ſmooth beneath.—Gathered by Jacquin in woods at Carthagena in South America, flowering in June, and ripening ſeed in September. It is a weak and trailing *ſhrub*, ſeldom riſing to the height of more than fifteen feet, and reſting its long, pliant, ſmooth branches upon the neighbouring buſhes. The *bark* is grey. *Leaves* oppoſite, oblong, ſomewhat obovate, blunt at each end, entire; ſmooth beneath; clothed with ſoft, depreſſed, ſcarcely viſible hairs above. Their length is from three to ſix inches. *Footſtalks* ſhort, with a pair of briſtle-ſhaped *ſtipulas* at the baſe. *Flowers* yellow, beautiful, an inch broad, in very long, compound, terminal cluſters.

2. H. *odorata.* Willd. n. 2.—"Leaves ovate, acute; ſmooth above; downy beneath."—Found by Iſert in Guinea.—A *ſhrub. Leaves* oppoſite, ovate, acute, entire, veiny;

dark green and ſmooth above; clothed with yellowiſh ſhaggy cloſe down beneath. *Cluſters* copious at the ends of the branches, axillary, forming a terminal leafy panicle, with downy ſtalks. The *flowers* are ſaid to be fragrant. *Fruit* exactly like the following. *Willdenow*.

3. H. *pinnata*. Willd. n. 3. (Flabellaria paniculata; Cavan. Diſſ. 436. t. 264.)—"Leaves pinnate with an odd one, ovate-oblong, alternate, ſmooth on both ſides."—Gathered by Smeathman at Sierra Leone. About this plant there is much obſcurity. Nothing brought by Smeathman anſwers to it, but ſome ſpecimens of his well agree with the preceding deſcription, except that the backs of the *leaves* are rather ſilvery than yellowiſh. Cavanilles may very reaſonably be ſuſpected of a miſtake with regard to the leaves, no plant of this natural order being known to have either compound or alternate foliage. We are therefore ſtrongly perſuaded that this ſuppoſed ſpecies is no other than the former.

HIRAM, in *Geography*, a poſt-town of America, in York county, Maine, containing 184 inhabitants.

HIRARA, in *Zoology*, the name of an animal of the Braſils, much reſembling the *hyæna*.

HIRCANIA. See HYRCANIA.

HIRCUS, TRAGUS, or *Goat*, in *Anatomy*, a part of the auricle, or outer ear; being that eminence next the temples.

HIRCUS, in *Aſtronomy*, a fixed ſtar of the firſt magnitude, the ſame with Capella.

HIRCUS is alſo a denomination given to the rank ſmell exhaling from the arm-pits; and which has its ſource in the axillary glands.

HIRCUS is alſo uſed by ſome writers for a comet, encompaſſed as it were with a mane, ſeemingly rough and hairy.

HIRE, PHILIP DE LA, in *Biography*, an eminent mathematician and aſtronomer, was born at Paris in the year 1640. His father took great care in having him inſtructed in thoſe branches of mathematics which ſhould lay a foundation for the ſtudy of the fine arts. After the death of his father, which took place when the ſon was only ſeventeen years of age, he paſſed ſome years in Italy, ſpending his time chiefly in the ſtudy of the mathematics, to which he devoted himſelf with the greateſt ardour. On his return to Paris he made himſelf known to the public by the ſecond part of a treatiſe on ſtone-cutting, printed in 1672, in continuation of Gerard d'Argues on the ſame ſubject. The reputation which he acquired by this performance, he encreaſed by his "Nouvelle Mèthode en Geometrie pour les Sections des Superficies coniques et cylindriques," and his treatiſe "De Cycloide." In the year 1678 he was elected member of the Academy of Sciences, and in the following year he publiſhed "Les nouveaux Elemens des Sections Coniques:" "Les lieux Geometriques:" "La Conſtruction ou Effection des Equations." In the ſame year, under the auſpices of Colbert, he commenced an undertaking, conjointly with M. Picard, in order to collect materials for a more correct general chart of the ſea-coaſt of France than had been before laid down: and viſited the province of Bretagne, where the two mathematicians made the ſurveys and obſervations requiſite for their deſign. In 1680 they proceeded to the coaſts of Guienne and Gaſcogny, and in 1681 M. de la Hire was directed to proceed alone to Calais and Dunkirk, in order to determine the exact poſitions of thoſe places. On this occaſion he took the opportunity of meaſuring the exact breadth of the ſtraits of Dover, which he found to be 21,360 toiſes. In 1682 he finiſhed his ſhare of the undertaking, and on his return to Paris he publiſhed his treatiſe "De Gnomonique," which he reprinted in 1698, in an enlarged form. From this time he frequently appeared before the public in the character of an author. And the diverſity of his productions, and his continual employments, give us ſome idea of the great labour which he muſt have undergone. His days, ſays his biographer, were almoſt uniformly ſpent in cloſe ſtudy, or in diſcharging profeſſional engagements, and a conſiderable part of his nights was frequently devoted to aſtronomical obſervations. Seldom did he enjoy any other relief from his labours than what aroſe from the exchange of one employment for another; nevertheleſs his health was generally good, till within a month of his death, which took place in 1718, after he had completed his 78th year. He was regarded as an honeſt and diſintereſted man, and as a good Chriſtian. Moreri. Hutton.

HIRLAW, or HARLEV, in *Geography*, a town of Moldavia, on the Bechlui; 30 miles N.W. of Jaſſy. N. lat. 47° 24'. E. long. 27° 6.

HIRMUND. See HEERMUND.

HIRPI, in *Ancient Geography*, a name diſtinguiſhing a number of families of Italy, at a ſmall diſtance from Rome, in the territory of the Faliſci, who every year marched over burning wood to mount Soracte, in order to offer a ſacrifice in honour of Apollo. It is ſaid that, on this account, they were exempt from going to war, and from all other charges. They are deſcribed in Virgil's Æneid. l. ii. v. 785:

> "Summe Deûm, ſancti cuſtos Soractis Apollo
> Quem primi colimus, cui pineus ardor acervo
> Poſcitur, et Medium freti pietate per ignem
> Cultores multa premimus veſtigia pruna."

Varro ſays, in ſpeaking of this practice of the Hirpi, that they applied ſome preparations to their feet in order to prevent their being burnt.

HIRPINI, a people of Italy, who formed a part of the Samnites; and as the term Hirpus ſignified in the Samnite dialect a wolf, they are ſaid to have migrated to their new habitations by tracing the ſteps of theſe animals. It was towards the end of the ſecond Punic war, that the Hirpini began to be diſtinguiſhed from the other Samnites. Their territory comprehended the towns of Beneventum, Candium, Abellinum, and Campſa.

HIRRIA, in *Geography*, a town of Hindooſtan, in Rohilcund; 28 miles S. of Pillibeat.

HIRSCHBERG, a town of Bohemia, in the circle of Boleſlau; 12 miles N. W. of Jung-Buntzel.—Alſo, a town of Sileſia, in the principality of Jauer, and next to Breſlau, the town of the moſt conſiderable trade in Sileſia, having many manufactures both in the town and neighbouring villages. The churches in the town belong to the Roman Catholics, but the Lutherans have purchaſed the privilege of erecting a church and ſchool without the walls. It has been once and again burned and pillaged; 20 miles S. W. of Jauer. N. lat. 50° 44'. E. long. 15° 48'.—Alſo, a town of Saxony, in the Vogtland; 14 miles S.W. of Plauen. N. lat. 50° 20'. E. long. 11° 58'.—Alſo, a town of Bavaria, in the principality of Aichſtadt, 22 miles N. E. of Aichſtadt.

HIRSCHFELD, a town of Saxony, in the circle of Erzgeburg; ſeven miles S. of Zwickau.—Alſo, a town of Luſatia, on the Neiſſe; 40 miles E. of Dreſden. N. lat. 50° 56'. E. long. 14° 59'.

HIRSCHOLM, a town of Denmark, with a caſtle, in the iſland of Zealand, where Chriſtian VI. died in 1746; 12 miles N. of Copenhagen.

HIRSEL, in *Rural Economy*, a term employed among the northern ſtock-maſters, to denote the diviſion of ſheep into particular kinds.

HIRSON, in *Geography*, a town of France, in the department of the Aiſne, and chief place of a canton, in the diſtrict of Vervins; four miles N. E. of Vervins. The place contains 2150, and the canton 11,127 inhabitants, on a territory of 185 kiliometres, in 13 communes.

HIRST, in *Mining*, Ridge or Sow's-back, is applied by the colliers of Scotland, (ſee Willein's Min. Kin. 2d edit. i. 90.) to the tops or higher parts of undulating ſtrata, or thoſe which lay in HILL *and Trough*, ſee that article.

HIRTELLA, in *Botany*, ſo named by Linnæus, as he himſelf informs us, in the *Hortus Cliffortianus*, p. 17, from *hirtus*, hairy, becauſe of the hairineſs of its young branches. —Linn. Gen. 110. Schreb. 153, 824. Willd. v. 1. 1151. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 2. 40. Jacq. Amer. 8. Juſſ. 340. Lamarck. Illuſtr. t. 138.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Senticoſæ*, Linn. *Roſaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, its border in five deep, nearly ovate, ſpreading, unequal, permanent ſegments. *Cor.* Petals five, roundiſh, concave, ſlightly ſpreading, equal, deciduous. *Stam.* Filaments five, ſometimes but three, inſerted into the rim of the calyx on one ſide, very long, briſtle-ſhaped, flattiſh, permanent, at length rolled in ſpirally; anthers orbicular, of two lobes. *Piſt.* Germen ſuperior, roundiſh, compreſſed and ſloping, hairy; ſtyle thread-ſhaped, as long as the ſtamens, ariſing from the depreſſed ſide of the germen oppoſite to the ſtamens, near the bottom; ſtigma ſimple. *Peric.* Berry oval, ſwelling upwards, ſlightly compreſſed, ſomewhat triangular, the ſtyle and much of the hairineſs which clothed the germen remaining attached to its baſe on one ſide. *Seed* one, large, ſhaped like the pericarp. Aublet deſcribes it as a nut of two cells.

Eſſ. Ch. Calyx with five permanent ſegments. Petals five. Filaments inſerted into the rim of the calyx, very long, permanent, ſpiral. Style lateral. Berry ſuperior, with one ſeed.

The hiſtory of the ſpecies is ſingularly confuſed. We ſhall endeavour to collect under one view all that has been ſaid of them.

1. H. *americana*. Willd. n. 1. Swartz. Obſ. 94. Aubl. Guian. v. 1. 247. t. 98.—Cluſters upright, ſimple, axillary; their common ſtalk villoſe. Leaves oblong, pointed. Stamens five.—Native of Cayenne and Guiana. A *tree* 25 feet high or more, and ſix inches in diameter, with a reddiſh bark. *Branches* long, ſlender, ſcattered, and ſubdivided. *Leaves* alternate, oval, long-pointed, entire, ſmooth and green; the largeſt of them ſix inches long by 2½ broad. *Footſtalks* very ſhort, with a pair of awl-ſhaped, downy, deciduous *ſtipulas*. *Cluſters* axillary, long, hairy, reddiſh; their partial ſtalks alternate, with one or two little ſcale-like *bracteas* at their baſe. Segments of the *calyx* reflexed. *Petals* blueiſh, emarginate. *Stamens* five, all on one ſide of the flower, very long, blueiſh upwards, as are likewiſe their *anthers*. *Style* rough in its lower part with red hairs. This tree flowers in March. Swartz and Willdenow ſeem to depend entirely on Aublet for this ſpecies, yet they take it for the original one of Linnæus, which he ſaw in Piſo's herbarium, and which had five ſtamens. However this may be, what he deſcribes in the *Hortus Cliffortianus* had but three, and ſhould ſeem to be different. What he quotes in the *Species Plantarum*, ed. 2: 290. from Marcgraave's Braſil, t. 78. f. 2, and which he ſays is bad, does not at all agree with any *Hirtella*.

2. H. *triandra*. Swartz. Prodr. 51. Ind. Occ. v. 1. 508. (H. americana; Jacq. Amer. 8. t. 8.)—Cluſters compound, terminal, ſolitary, downy, looſely ſpreading. Leaves elliptic-oblong, pointed, naked on both ſides. Stamens three.—Native of woods, by the ſides of torrents in Jamaica, Hiſpaniola, and other parts of the Weſt Indies, flowering in April and May. The *branches* are beſprinkled with minute warts, their young extremities clothed with depreſſed ſattin-like down. *Leaves* about three inches long, nearly elliptical; with a taper point, contracted, and ſomewhat rounded at their baſe, naked and ſhining, but rather rough to the touch. *Cluſter* five or ſix inches long, ſimple in Jacquin's figure, very compound in our ſpecimens. *Fruit* an inch long, or more, ſlightly hairy. Willdenow conſiders this as the *Hirtella* of Hort. Cliff. Swartz ſays the *petals* are white, *ſtamens* three, with the rudiments of from two to five minute filaments in the vacant ſpace oppoſite to them.

3. H. *pendula*. Herb. Linn. fil.—Cluſters compound, terminal, long, pendulous, hairy. Leaves oblong, pointed; heart-ſhaped at the baſe; downy beneath. Stamens three.—Native of the Weſt Indies? The *leaves* exactly reſemble thoſe in Aublet's figure of *H. americana*, both in ſize and figure, but are rough with ruſty down at the back. The *cluſters* are above a foot long, ſolitary, terminal, ſtalked, clothed all over with denſe, prominent, ruſty, ſhort hairs; their partial ſtalks generally cloven and two-flowered, the lower ones many of them much more compound and forked. *Calyx* very hairy; ſilky within. *Stamens* three, long and twiſted, as well as the *ſtyle*, which is quite ſmooth throughout. *Fruit* above an inch long, ſmooth, obovate, compreſſed upward, and emarginate. Fine ſpecimens of this, in the herbarium of the younger Linnæus, appear to have made a part of a numerous collection of Weſt Indian plants given him, when in England, by ſir Joſeph Banks. Yet we find no deſcription in Swartz or any other author applicable to them, nor does the above name any where occur.

4. H. *paniculata*. Swartz. Prodr. 51. Ind. Occ. v. 1. 510. Vahl. Symb. faſc. 2. 43. t. 31.—Cluſters compound, terminal, erect, hairy, ſometimes aggregate. Leaves oval, acute, ſhining; their ribs hairy beneath. Stamens five or ſix.—Native of Guiana. The *leaves* are peculiarly ſhining on both ſides, though their colour is paler at the back, and the ribs there hairy. In length they greatly vary, but ſcarcely in breadth. The young *branches*, *flower-ſtalks*, and *calyx*, are briſtly with long prominent tawny hairs. *Stamens* in our ſpecimens ſix. Some of Linnæus's remarks appear to indicate this ſpecies as what he had ſeen.

HIRTIUS, AULUS, in *Biography*, was an officer under Julius Cæſar, and wrote a ſupplementary part of the Commentaries publiſhed in his name. The books compoſed by Hirtius are the eighth of the Gallic war, and thoſe of the Alexandrine and African wars. Of the two latter he received his information partly from Cæſar's own mouth. His ſtyle is good, but his narrative is reckoned leſs clear than that of Cæſar himſelf. He was made conſul, together with Vibius Pauſa in the year B. C. 43, and the conduct of the war againſt Antony was committed to them in conjunction with the young Octavianus. He gave Antony a conſiderable check in the neighbourhood of Mutina, but his ardour carrying him too far into the enemy's quarters, he received a wound which laid him dead on the ſpot. Univer. Hiſt.

HIRUDELLA MARINA, in *Natural Hiſtory*, the name of a very remarkable little animal of the leech kind. The body of this creature is roundiſh and oblong, and adorned with many longitudinal lines or furrows; it is about an inch in length, and is of a greyiſh colour, and ſomewhat tranſparent; the bowels are ſeen through the ſkin, and appear at firſt ſight like ſtreaks on its ſurface; in the middle of the belly there is a remarkable protuberance, which, when cloſely examined, is found to be a muſcular body in form of a ſpherical bladder; this, when moſt diſtended, has the appearance of a ſpherical air-pump, and has all the properties of that machine, to be employed for the ſervice of the animal, and at its pleaſure. It reſembles, in its common figure, the cup of an acorn, with the mouth a little contracted. The head of the animal is of the ſame figure with that of the common leech, and ſerves to ſuck the juices of other animals in the ſame manner as in that inſect. The part of the body which reaches from the head to the middle protuberance is of a very irregular form, frequently in motion, and continually changing its figure; but the other part moves more ſlowly, and leſs frequently, and preſerves its ſhape unaltered. The protuberance has two motions, expanſion and undulation.

When the creature has a mind to fix itſelf any where, it does it by means of this protuberance, which it applies cloſely down to the ſubſtance, and void of air. Hence the external air ſo firmly preſſes its ſides againſt the ſubſtance, that it is not eaſy to remove it. When the creature changes its place, it draws the head round to the protuberance, and looſens it ſo as to be able to change its place as it has occaſion.

When this creature is kept out of water, it dies in a few hours; and when after being thus kept out a few minutes, it is put into ſea-water, it immediately darts out a fine green thread from its mouth; this it uſually makes of the length of its body, or thereabouts, though it varies it occaſionally; and by means of this it ſuſpends its body any length that it pleaſes in the water. It ſeems to be calculated only for living in the bodies of fiſh, for the ſea-water ſoon kills it; and it is obſerved to diminiſh its bulk very ſenſibly all the time that it is kept in it. Phil. Tranſ. No 410.

HIRUDO, in *Zoology*, a genus of Vermes, the body of which is oblong, truncated at both ends, unarmed, and cartilaginous; and the progreſſive motion is effected by dilating the head and tail, and contracting itſelf into an arch. Linn. To this eſſential character it ſhould be added, that the two extremities of the true hirudo are capable of being dilated into a fleſhy diſk, by means of which it can affix itſelf firmly to the ſkin of animals, and the mouth, which is triangular, ſituated under the anterior part of the body.

This is a genus of aquatic worms, known in England by the name of leech; ſeveral of its ſpecies inhabit our waters, and two in particular, the common or medicinal leech, and the horſe leech, are ſo well known as to be familiar to every one. The body in the leech tribe is compoſed of a great number of rings; the ſkin more or leſs ſmooth, and the head, when in a ſtate of contraction, more pointed than the tail; the opening of the mouth is triangular, and armed with three ſtrong teeth, beſides a numerous aſſemblage of ſmaller ones, and a ſucker at the bottom, by the aſſiſtance of which it draws the blood from the wound inflicted by this formidable armament of teeth in the fleſh of the bleeding animal. The teeth of the leech are powerful enough to penetrate not only through the ſkin of man, but alſo that of horſes and cattle, examples of which very frequently occur when the latter bathe in the water. The hirudo tribe reſpire by the mouth. The greater portion of the ſpecies are furniſhed with eyes, the number of which however varies according to the ſpecies, being ſometimes eight, in others ſix, and again in others no more than two. Every individual of the leech tribe, like thoſe of the ſnail, is complete in its own conformation, being, as Redi obſerves, of both ſexes, and often producing their young alive. Their common ſubſiſtence is the blood of quadrupeds, and other ſanguineous animals which they caſually meet with in the water, and which, as they can bear an abſtinence of ſome weeks or even months, they generally find in ſufficient abundance. Should it prove otherwiſe they prey on worms and the larvæ of aquatic inſects, which they ſuck to death, as they ſubſiſt only on their fluids, and the ſmall portion of blood the vital parts of ſome particular kinds afford. The leech ſwims in the manner of the eel, and ſome of the ſpecies live in ſalt waters, though the greater number are confined entirely to the freſh waters, ſome preferring the clear and pure element, and others the ſtagnant pools and ditches, ponds, and marſhes which moſt abound with aquatic plants. There is only one ſpecies (the common kind), that can be applied with ſafety to medicinal purpoſes.

Species.

MEDICINALIS. Elongated, blackiſh, lineated above with yellowiſh; beneath ſpotted with yellow. *Hirudo medicinalis*, Ray. *Hirudo major et varia*, Geſn. *Medicinal leech.*

Inhabits ſtagnant ponds and ditches in Europe; the body is compoſed above of numerous annular wrinkles, which are contractile at pleaſure, and marked with variegated lines; mouth ſmaller than the tail; the laſt compoſed of an annular muſcle, by which it has the power of faſtening its body firmly to any ſmooth ſurface. The medicinal virtues of this ſpecies as a phlebotomiſt is well known.

SANGUISUGA. Elongated, olive brown, with an ochre-yellow marginal band. Linn. *Hirudo maxime vulgaris*, Ray. *Horſe leech.*

Abundant in ſtagnant waters; the length from four to ſix inches; the body above dull olive black or brown; beneath paler, with ſometimes a few black ſpots, and tail thicker than the head. Sucks blood with great avidity and in large quantities.

LINEATA. Elongated and grey, with four dorſal lines diſpoſed longitudinally. Müll.

A rare ſpecies, found early in the ſpring in ſtagnant waters; the length about an inch and a half; body annulated with numerous wrinkles, and ſix deep black eyes placed in a double row.

VULGARIS. Elongated, yellow-brown, with eight eyes diſpoſed in a lunate ſeries. Müll. *Hirudo octoculata*, Bergm. &c.

Length fifteen lines, the body ſometimes brown, and without ſpots; ſometimes ſprinkled above with yellow dots, or with dots of black, or varied in the middle with a knotty line, and a lateral blackiſh one; and ſometimes yellowiſh with longitudinal lineations, the middle knotty, and the lateral ones with remote red dots; eyes eight in general, or ſometimes nine.

STAGNALIS. Elongated, cinereous, with two eyes. *Hirudo ſtagnalis*, Linn. *Hirudo bioculata*, Müll.

Body whitiſh, pellucid, ſprinkled with cinereous dots and plaited at the ſides; eggs about forty, ſurrounded by a pellucid circle. The young, after excluſion, adhere by their tails to the abdomen of the parent. Length nine lines.

COMPLANATA. Body dilated, cinereous, with a double tuberculated line on the back; the margin ſerrated. Müll. *Hirudo lateribus attenuatis*, Hill. *Hirudo ſex-oculata.* Bergm.

Length four lines, the body with tranſverſe bands, compoſed of three pale lines, the margin whitiſh; body beneath grey; head pointed and white, with ſix eyes; tail orbicular and cinereous. Found in ſhallow ſtreams.

HETEROCLYTA. Dilated, pellucid and yellow, with entire margin. *Hirudo heteroclyta hyalina poſtice lutea*, Linn. *Hirudo hyalina*, Müll.

Body flattiſh, the anterior part pointed, poſterior rather broad, and marked above with numerous fine longitudinal ſtriæ of black ſpecks, and remote browniſh ones ; head white, eyes four or ſix ; eggs numerous, ſpherical, green and ſurrounded with a pellucid ring ; the young that eſcape firſt are yellow, the latter green.

Geometra. Elongated, yellowiſh, with a pinnate white dorſal line. *Hirudo geometra, teres, extremitatibus dilatatis,* Linn. *Hirudo piſcium,* Müll. *Hirudo ore caudaque ampla,* Friſch.

Inhabits freſh waters, and fixes itſelf to the bodies of fiſhes ; eyes four, colours varying.

Inhabits freſh waters, and fixes itſelf on the bodies of trout and other fiſh after the ſpawning ſeaſon ; length eight lines, its progreſſive motion like the movement of a compaſs in meaſuring ; body tapering before, and very broad at the tail ; eyes four ; colour variable.

Tessulata. Cinereous with a teſſellated margin ; eyes eight, in a double longitudinal row. Müll.

Length eighteen lines ; the body dilated and covered with black ſpecks ; above with orange and white ſpots ; beneath grey, with two rounded white ſpots in the middle. Found in rivulets.

Marginata. Dilated, brown, with a teſſellated margin, and four eyes. Müll.

Inhabits rivers, and reſembles the laſt ; the length ten lines ; head obtuſe before and narrowed behind, white, pellucid, and marked with two tranſverſe brown bands ; abdomen reddiſh brown with very minute ſtriæ meeting beneath in doubled brown lines ; back with five rows of whitiſh dots, the lateral margin white, with a double brown line divided into ſquare patches ; tail orbicular and pale, with brown ſpots on the margin.

Grossa. Dilated, yellowiſh, and divided on the forepart. Müll.

A marine ſpecies found ſometimes within the ſhell of Venus exoleta ; the length about twelve lines, the breadth ſeven. The body marked with fine white ſtriæ, the anterior part narrower and obtuſe ; eggs very numerous, ſpherical, and ſwimming in a gelatinous fluid.

Hippoglossi. Dilated, whitiſh, with a double white eye in the middle of the body. Müll.

Inhabits the ſea and infeſts fiſhes, being often fixed to the ſkin of the turbots and holibuts. The body is oval, depreſſed, pellucid, a little pointed before, and ending in a globular ring behind ; head ſomewhat triangular with a cinereous ſpot each ſide ; eyes not viſible ; tail with a row of tubercles beneath from the centre, and towards the middle two hooks.

Muricata. Body round, tapering, tuberculated, and furniſhed with two ſhort horns on the head. Gmel.

A marine ſpecies that infeſts fiſhes, leaving a black mark on the ſpot to which it adheres ; the head is larger than the tail ; body ſtrongly annulated and tuberculated on the rings ; the tail much dilated.

Crenata. Slightly depreſſed, ſub-oval, with tranſverſe annular ſtriæ, and crenulated margin. Linn. Tranſ.

Found in ſhallow ſtreams among aquatic plants. The colour greeniſh, inclining to aſh, the upper ſurface ſomewhat convex ; its interanea are very viſible by means of its vitreous tranſparency, and appear like ſo many granula ; eyes two and much approximated.

It appears to us not altogether improbable, that among the numbers of ſpecies above deſcribed, ſome few at leaſt will be hereafter found to belong rather to the genus Planaria, than that of Hirudo.

In the firſt volume of the Linnæan Tranſactions Dr. Shaw deſcribes an animal of the molluſca family, under the title of hirudo viridis, and which, from a note annexed to another paper, in the ſame volume of the ſame work, that author afterwards conſidered referrable to the planaria tribe. The correction of this is material, as ſome writers, depending on the former authority, ſtill retain it among the hirudines. In the removal of this ſpecies to the genus planaria, it will be proper to change the trivial appellation by which it was before diſtinguiſhed, becauſe another ſpecies of planaria, very different from the animal deſcribed by Dr. Shaw, has been previouſly deſignated by the appellation of *viridis*.

The two kinds of vermes introduced to notice by the Rev. Mr. Kirby, in the ſecond volume of the Linnæan Tranſactions, under the names of *hirudo alba,* and *hirudo fuſca,* are, perhaps, planariæ likewiſe ; nor are we entirely ſatisfied that the ſpecies *crenata,* of the ſame author, and which is alſo deſcribed in the ſame paper, is ſtrictly of the hirudo tribe. Mr. Kirby himſelf ſuggeſts the idea, that they may be ſufficiently diſtinct to conſtitute a new genus. Though we agree with Mr. Kirby in this reſpect, and are inclined with Dr. Shaw to think, they may with propriety be referred to the planaria genus, we cannot ſo far aſſent to the opinion of Dr. Shaw, expreſſed in the note (p. 320.) as to believe the H. crenata to be the young of the Linnæan hirudo geometra. This laſt is delineated in all its ſtates of growth by Roeſel under the title of *hirudo piſcium,* (t. 3.) and the ſlighteſt compariſon of theſe figures, with thoſe of hirudo crenata in the Linnæan Tranſactions, will be ſufficient, we imagine, to diſcountenance ſuch conjecture. There is one diſtinction, at once ſo obvious, that we cannot refrain to mention it ; this conſiſts in the number of the eyes in the two animals, the hirudo geometra poſſeſſing no leſs than four, and the ſpecies crenata no more than two.

We ſhall finally direct our attention to the *hirudo branchiata* of the Linnæan Tranſactions, (vol. i.) a ſpecies of vermes, which is not, we believe, conſigned with any abſolute certainty to the genus at preſent under conſideration : in this reſpect, at leaſt, it is confeſſedly ambiguous, and as ſuch, appears to have excited ſome little curioſity in the minds of continental naturaliſts. The obſervations of Boſc, on this particular ſubject, appear to us rather intereſting and worthy of being tranſcribed, and this, the more eſpecially, ſince they do not ſeem to place the account of this ſingular animal, as originally given by its Engliſh obſerver, in that clear and ſatisfactory point of view we could wiſh for, or expect.

" On trouve (ſays M. Boſc) dans le premier volume des Actes de la Société Linnéenne de Londres, la deſcription et la figure d'une ſangſue trouvée ſur la tortue de mer, qui a de chaque côté ſept branchies rameuſes fort ſaillantes. Il eſt évident que l'on doit en former un genre nouveau, ſurtout ſi ce ſont réellement des branchies ; mais Mentzies, l'auteur de ce memoire, n'entre pas dans des details ſuffiſans pour pouvoir l'aſſurer d'une maniere poſitive." We admit with M. Boſc, that the ingenious writer, to whom we are indebted for the diſcovery of this curious creature, does not enter ſo fully into detail as to enable us to aſcertain the genus to which it may belong, or rather, we might ſay, to authoriſe its removal into any other genus, were we diſpoſed to conſider its preſent ſituation improper. The concluſion of Boſc, that it does not appertain to the hirudo genus, is perhaps too incautiouſly aſſumed : the animal, he tells us, has ſeven " branchies" on each ſide, and it is upon the ſuppoſed exiſtence of theſe, that he reaſons on the propriety of its forming a new genus, though he himſelf, at the ſame time, doubts whether the lateral appendages to which he alludes be " branchies" or not. The exiſtence of ſuch branchiæ would unqueſtionably be ſufficiently deciſive to remove it from the hirudo tribe, ſince the latter reſpire by the mouth, but as to the actual exiſtence of ſuch branchiæ it is poſſible we may miſconceive the fact: or indeed the ramoſe appendages to which he adverts may be truly ſuch, for there is nothing, at leaſt, in the deſcription given by Mr. Menzies, either to ſupport or contradict this idea.

The deſcription of this creature, as given by Mr. Menzies, is briefly as follows: H. depreſſa, attenuata, albida, ſetis lateralibus ramoſis utrinque 7; interaneis fuſcis, bifidis, perlucentibus; or, as may be rendered to the Engliſh reader: depreſſed, attenuated, whitiſh, with ſeven ramoſe briſtles each ſide; inteſtines brown, bifid, and pellucid: and in the general account accompanying this ſpecifical deſcription, theſe lateral appendages are ſaid to be ſoft, pellucid, branchy briſtles.

Thus it is not apparent, from any obſervation that has fallen from Mr. Menzies, that theſe lateral appendages are real branchiæ, or reſpiratory organs: having ſtated this, it is fair to add, that the concluſion of Boſc, though not to be aſſumed from the remarks of its original deſcriber, may be nevertheleſs accurate, and probably is ſo. The appearance of the animal, if any confidence can be placed in the delineation, ſeems to favour this conception. The magnified figure of one of theſe lateral ramoſe appendages, as ſhewn in the plate in particular, accords exceedingly in appearance with the breathing organs of ſome of the molluſca tribe, as exemplified in various ſpecies of the nereides, aphroditæ, and others; and ſhould the animal really poſſeſs ſuch breathing organs, its internal organization muſt be altogether ſo very different from that of the hirundines, that there can be no doubt of the propriety of inſtituting a new genus for its reception.

HIRVENSELMI, in *Geography*, a town of Sweden, in Tavaſtland; 75 miles E. of Tavaſthus.

HIRUNDO, in *Ornithology*, a genus of the Paſſerine order, diſtinguiſhed by the following eſſential character. The bill is ſmall, weak, curved, ſubulate, and depreſſed at the baſe; gape larger than the head; tongue ſhort, broad, and bifid; wings long; tail moſtly forked.

This genus is divided by ſome writers into two ſections, according to the poſition of the feet, the firſt having three toes placed forwards and one behind; the other with all the toes placed forwards; the former are the *ſwallows*, the other the *ſwifts* of Engliſh authors. In both the noſtrils are open, and the legs ſhort.

Moſt of theſe birds frequent marſhy places, and ſkim the ſurface of the ground and water in ſearch of inſects, which they catch on the wing with great dexterity, by means of the enormous gape of their jaws. Inſects are their peculiar and almoſt excluſive food, and it is for this reaſon ſwallows are regarded with a degree of ſuperſtitious tenderneſs in every country that abounds with noxious creatures of that deſcription. Swallows are equally incapable of bearing the extremes of heat and cold, and on that account, except in very temperate weather, they are oftener ſeen on the wing in the morning before the heat of the day becomes oppreſſive, and in the evenings towards ſunſet than at any other times.

Theſe birds walk indifferently owing to the ſhortneſs of their legs, and from the ſame cauſe riſe off the ground, or any low ſituation with difficulty; and hence when they go to reſt, they almoſt invariably ſuſpend themſelves againſt the ſides of walls or other elevations, from which they are enabled to renew their aerial evolutions with facility.

The annual migration of the ſwallow has been long the theme of curious obſervation among naturaliſts, and few topics of this kind have met with more ample diſcuſſion, or given birth to more extraordinary opinions. The truth, however, is, that the migrations of the ſwallows, like thoſe of moſt other birds of paſſage, may be eaſily explained, ſince nature does not in this inſtance, more than any other, deviate from her ordinary courſe, and of this we have the moſt poſitive aſſurances both in reaſon and in fact. Nearly all the ſpecies of the ſwallow-tribe are found in the two great continents, remaining in the northern part during ſummer, appearing near the equinox in ſpring, and again retiring to more temperate climates as the autumn approaches. Part remain in hot countries all the year, as in Egypt, Æthiopia, Libya, and the countries between the tropics. They regularly paſs alternately acroſs the Archipelago from Europe to Africa, and from Africa to Europe as the ſeaſons change; this is the general progreſs of all the ſpecies of the ſwallow tribe that inhabit Europe; and the ſame courſe of migration from one part of the world to another is obſervable in the common ſwallow, the ſpecies whoſe migrations have excited ſuch very peculiar attention among modern writers as well as thoſe of remote antiquity; we ſhall enter more fully into the details of this intereſting ſubject under the article SWALLOW.

The hirundo genus, including the ſwallow and the ſwift family, contains about forty ſpecies, the greater part of which are ſwallows, the ſwifts being few in number.

Species.

RUSTICA. Front and chin cheſnut; tail-feathers, the two middle ones excepted, with a white ſpot. Linn. Kram &c. *Hirundo domeſtica*, Geſn. &c. *L'Hirondelle de Cheminée*, Briſſ. *Common or chimney ſwallow*, Will. Donov. Br. Birds, &c.

The common ſwallow is an inhabitant of moſt parts of the globe, being of the migratory kind, and viſiting different countries at particular ſeaſons. About the latter end of March it arrives in England, and remains till September, during which intervening period it frequents houſes, under the roofs, or in the chimnies of which it uſually breeds; the neſt is compoſed of mud, intermixed with chaff, feathers, &c. and contains from four to ſix eggs of a whitiſh colour ſpeckled with red. Previouſly to its departure it aſſembles in vaſt flocks on the tops of houſes, churches, or other elevations, from whence they all depart in a body with extreme regularity, and as it appears under the directions of particular leaders. Thoſe from Europe paſs the winter in Africa, South America, India, and other ſimilar climates, returning again towards the north in ſpring. Like the reſt of its tribe the food of the ſwallow conſiſts of inſects, which it takes on the wing. This hirundo (ſays an ingenious writer) though called the chimney-ſwallow, by no means builds altogether in chimnies, but often within barns and out-houſes againſt the rafters. In Sweden ſhe builds in barns, and is called ladu ſwala, (the barn ſwallow.) Beſides, in the warmer parts of Europe there are no chimnies to houſes; and in theſe countries ſhe conſtructs her neſt in porches, gateways, galleries, and open halls. With us the ſpecies breeds in chimnies, and loves to haunt thoſe ſtacks where a conſtant fire is kept, no doubt for the ſake of the warmth. But then it cannot ſubſiſt in the ſhaft at the bottom of which the fire is burning; it prefers one adjoining, in which it builds its neſt about five or ſix feet below the chimney opening at the top. The neſt is conſtructed of mud mixed with ſhort pieces of ſtraw, in the form of the half of a deep diſh, and is lined with feathers and graſs, which it catches floating in the air. The addreſs with which the ſwallow aſcends and deſcends with ſecurity through ſo narrow a paſs is wonderful. When hovering over the mouth of the funnel, the vibration of her wings, acting on the confined air, occaſion a rumbling noiſe like thunder. It is not improbable that the dam ſubmits to this inconvenient ſituation ſo low in the ſhaft, in order to ſecure her brood from rapacious birds, and particularly owls, which frequently fall down chimnies, perhaps in attempting to get at theſe neſtlings. The firſt brood of young are hatched the laſt week in June, or the firſt week in July. The progreſſive method by which the young are introduced into life is very amuſing; firſt they emerge from the ſhaft with difficulty enough, and often fall down into the room below; for a day or two they are fed on the chimney top, and then are conducted to the dead leafleſs bough of ſome tree, where, ſitting in a row, they are attended with great aſſiduity, and may then be called porchers. In a day or two more they become flyers, but are ſtill unable to take their own food, therefore they play about near the place where the dams are hawking for flies, and when a mouthful is collected, at a certain ſignal given, the dam and the neſtling advance riſing towards each other, and meeting at an angle, the young one all the while uttering a quick note of gratitude and complacency. All the ſummer long is the ſwallow a moſt inſtructive pattern of unwearied induſtry and affection, for from morning to night while there is a family to be ſupported ſhe ſpends the whole day in ſkimming cloſe to the ground, and in the moſt ſudden and lively evolutions. Avenues and long walks under hedges, and paſture fields, and mown meadows where cattle graze, are her delight, eſpecially if there are trees interſperſed; becauſe in ſuch places inſects abound. The ſwallow is the firſt to announce the approach of birds of prey to the houſe martin and other little birds, warning them of danger by its ſhrill alarming note, and aſſociating them in a body to purſue and buffet the intruder. The ſwallows drink as they fly ſipping the ſurface of the water, and in hot weather are often ſeen dropping into the water many times together, to waſh and cool themſelves. The ſong of this bird is very pleaſing.

The ſwallow, though generally regarded in moſt countries with a kind of ſuperſtitious veneration for its utility in deſtroying pernicious inſects, is in Italy and ſome other parts eſteemed a bird of chaſe, and the hunting of them at particular ſeaſons a favourite diverſion. The fleſh is conſidered as a delicacy little inferior to that of the ortolan.

Tahitica. Blackiſh-brown with a purple gloſs above; front and neck beneath purple-tawny; belly and vent ſooty; tail, bill, and legs black. Gmel. *Otaheite ſwallow*, Lath.

Length five inches; the bill black; irides brown. Inhabits the mountainous parts of Otaheite.

Esculenta. All the tail-feathers with a white ſpot. Oſbeck. *Hirundo riparia Cochinſinenſis*, Briſſ. *Hirundo nidis edulibus*, Bont. *Apus marina*, Rumpf. *Salangane*, Buff. *Eſculent ſwallow.*

The eſculent ſwallow is ſaid to be leſs than the wren, and only two inches and a quarter in length; the bill black; irides yellow; upper part of the body brown; the under whitiſh; tail forked, with each of the feathers white at the tip; and the legs brown. This deſcription was taken by Briſſon from a drawing of the bird by Mr. Poivre, the figure of which is repeated in the ornithology of Briſſon. Mr. Marſden, however, deſcribes the bird to be about the ſize of the common martin, and Dr. Latham, when he publiſhed his Synopſis, was inclined to think the bird at leaſt of that ſize; this he was induced to believe from the ſize of the eggs which accompany the neſt of the eſculent ſwallow, now in the Britiſh Muſeum, and which are as large as thoſe of the martin, and of the ſame colour.

The neſts of theſe birds, in ſhape reſembling a lemon cut down the middle, and compoſed of gelatinous ſubſtances alone, render the ſpecies worthy of particular curioſity; the neſt itſelf being not only edible, but conſidered as one of the greateſt delicacies of the table by the luxurious Aſiatics. This neſt, the weight of which is about half an ounce, adheres by one ſide to the rock. Authors differ greatly as to the materials of which it is compoſed; Oſbeck and others imagine it to conſiſt of ſea-worms of the molluſca order: Forreſter conceives it to be the ſea-qualm, a ſort of cuttle-fiſh found in thoſe ſeas, or a glutinous ſea-plant, called agal-agal. Or it has been again ſuppoſed they rob other birds of their eggs, and apply the white of them to that purpoſe. The fabrication of theſe neſts is very obvious, being compoſed of ſeveral concentric layers, which are ſeen diſtinctly when the neſt is broken tranſverſely. Theſe neſts are found in vaſt numbers in certain caverns in the various iſlands of the Soolo Archipelago, ſituated between the longitude 117° and 120°, and latitude 5° and 7°; particularly in three ſmall iſlands, or rather rocks, in the caverns of which the neſts are found fixed to the ſides in aſtoniſhing numbers. They are alſo found in amazing quantities on a ſmall iſland called Toc, in the ſtraits of Sunda; the caverns of which are lined with the neſts; but no where in greater abundance than about Croee, near the ſouth end of Sumatra, four miles up a river of that name. But they are not peculiar to the above places; for they are likewiſe common from Java to Cochinchina on the north, and from the point of Sumatra weſt, to New Guinea on the eaſt; where the ſea is ſaid to be covered with a viſcous ſubſtance, like half-melted glue, and which ſome ſuppoſe the birds either take up from the ſurface by means of the bill during flight, or pick up from the rocks when left there by the waves.

The neſts are of two colours, the one whitiſh, the other black, and apparently dirty. The whitiſh kind is perfectly clear, and is applied to the purpoſes of thickening broths, and ragouts made of chickens, and to which they contribute, it is ſaid, an exquiſite flavour. Theſe neſts are firſt ſoaked in water to ſoften, are then pulled to pieces, and, after being mixed with ginſeng, are put into the body of the fowl. The whole is then ſtewed in a pot with a ſufficient quantity of water, over a fire of coals all night, and the morning following it is fit to be eaten. The beſt neſts are of a pure yellowiſh white, and half tranſparent, and theſe ſell in China from one thouſand to fifteen hundred dollars the *pekul*, a weight equal to about 123lbs. Engliſh. Thoſe of a black colour being dirty, are worth but about twenty dollars the pekul, being ſerviceable only in making glue. The gatherers take all they can, in the hopes of compelling the birds to make freſh neſts, and thus render their next gathering more profitable. The Dutch alone are ſaid, a few years ago, to export from Batavia a thouſand pekuls of theſe neſts every year, the whole of which are brought from the iſles of Cochinchina, and thoſe lying to the eaſtward. At Sumatra the bird is known by the name of *layong-layong*.

The above-mentioned neſts, (examples of which occur pretty frequently in the cabinets of the curious,) are ſuppoſed to belong to the bird deſcribed by Briſſon, but of this we are not entirely aſſured: it was before obſerved, that the bird deſcribed by Marſden was far ſuperior in ſize to that mentioned by Briſſon, and from the recent obſervations of writers, it does really appear theſe neſts may be the fabrication of ſome other bird with which we are at preſent unacquainted. The idea entertained by ſir George Staunton, (Emb. China) ſeems to be that theſe neſts may be the produce of more than one ſpecies of ſwallow, and this opinion is extremely plauſible, though it muſt be at the ſame time admitted the ſubject is too much enveloped in obſcurity to authorize that concluſion. In confirmation of the ſuggeſtion we may add that it is not long ſince another ſort of ſwallow, very different from that recorded by Briſſon, was brought, with the neſt, as the eſculent ſwallow of the Indies, to ſir Joſeph Banks; and which in ſize agreed much better with that deſcribed by Marſden, than the bird deſigned by Poivre. An account of this newly obſerved kind is inſerted in the ſecond Supplement of Dr. Latham's work: its ſize is equal to that of the common ſwallow; the beak ſmall and black, and the opening ample: the whole of the plumage above is gloſſy black; beneath aſh; wings long; tail forked, with all the feathers rounded at the tip; and the legs blackiſh.

Borbonica. Blackiſh fuſcous, beneath grey, varied with longitudinal brown ſpots; tail equal; bill and legs black. Gmel. *Grande hirondelle*, &c. Buff. *Wheat ſwallow.*

Size of the ſwift; the bill black, and the tail even at the end. Inhabits the iſle of France, where it is known by the name of hirondelle des blés, or wheat ſwallow, from its frequenting places newly ſown with that grain, and feeding on it. The ſpecies alſo feeds on inſects, in queſt of which it often follows herds of cattle, and relieves them from theſe winged tormentors, by devouring them. The female lays two eggs, of a grey colour, dotted with brown; the neſt is compoſed of ſtraw and feathers. There is a variety of this bird having the three outer tail-feathers whitiſh at the tips.

Francica. Blackiſh, beneath and rump whitiſh or grey. Gmel. *Hirondelle de Bourbon*, Buff. *Grey-rumped ſwallow*, Lath.

Length four inches and a quarter; inhabits the iſle of France, but is not common, and is found chiefly in the neighbourhood of freſh waters.

Americana. Blackiſh fuſcous, gloſſed with blue and green; beneath whitiſh; rump and vent rufous; quill-feathers whitiſh within; tail equal. Gmel. *Hirondelle à croupion roux et queue carrée*, Buff. *Rufous-rumped ſwallow*, Lath.

Inhabits about the river Plata, in South America; length ſix inches and a half. A variety of this bird has the throat rufous.

Urbica. Blackiſh; beneath white; tail-feathers without ſpots. Scop. &c. *Hirundo minor ſ. ruſtica*, Briſſ. *Hirundo agroſtis*, Geſn. *Petit martinet*, Buff. *Hauſſchwalbe*, Friſch. *Martin, martinet*, or *martlett*, Willd. Donov. Br. Birds, &c.

This ſpecies is more frequent than the common ſwallow; the length five inches and a half; its bill black; mouth yellow; rump white; and legs covered with ſhort white down. This bird is equally common throughout moſt parts of Europe, and extends over great part of America: it builds under the eaves of houſes, but not in chimneys, like the common ſwallow. It lays twice in the year, from five to three, or only two eggs, the colour of which are white, with the broader end rather duſky.

Panayana. Black; beneath white; frontal ſpot and chin rufous yellow; collar black. Gmel. *Hirondelle d'Antique*, Sonner. *Panayan ſwallow*, Lath.

The ſize of the ſand martin; bill black; wings and tail of equal length; the legs black. Inhabits the iſland of Panay, one of the Philippines.

Rufa. Shining black; beneath rufous; front whitiſh. Gmel. *Hirondelle à ventre roux de Cayenne*, Buff. *Rufous-bellied ſwallow*, Lath.

Capensis. Blackiſh-blue, beneath yellowiſh, with blackiſh ſtreaks; cap rufous; lateral tail-feathers with a white ſpot. Gmel. *Hirondelle au capuchon roux*, Buff. *Cape ſwallow.*

Native of the Cape of Good Hope; the length ſeven inches; bill half an inch in length, and black; the legs duſky. It is ſaid to build its neſt in houſes againſt the ceilings, the form rounded with a cylindrical entrance, the exterior ſubſtance mud, with an inner lining of feathers. The female lays four or five eggs, which are ſpeckled.

Riparia. Cinereous; chin and belly white. Linn. *L'Hirondelle de rivage*, Briſſ. *Hirundo riparia*, Aldr. *Sand martin*, or *Shore-bird*, Will. Donov. Br. Birds, &c.

Inhabits ſandy places in Europe and America; the length four inches and three quarters; bill blackiſh; legs blackiſh, and feathered behind. The female lays from five to ſix eggs, of a clear white colour, either in a neſt, which it builds of dried fibres, ſtraw, and feathers; or in hollows of trees, or cavities in the ſand, and ſometimes in the ſteep ſhores of lakes and rivers.

Rupestris. Mouſe-colour, beneath whitiſh; tail ſubequal, the feathers with a white ſpot on the inner web. Scop. *Rock ſwallow.*

Makes its neſt of clay in the hollows of rocks, and inhabits Carniola. Size of the common martin.

Montana. Mouſe colour, beneath rufous; quill and tail-feathers grey brown, edged with rufous, the latter, except the middle and outer ones, with a white ſpot within. Gmel. *Hirondelle griſe des rochers*, Buff. *Cragg ſwallow*, Lath. *Mountain ſwallow.*

Inhabits the mountains of Auvergne and Dauphiné, and alſo thoſe of Savoy, arriving at the latter about the middle of April, and departing in the middle of Auguſt. The length is five inches and a half; the bill black; legs covered with grey down and mixed with brown, claws black.

Purpurea. Entirely violet; tail forked, Kalm. *Hirundo apus Carolinenſis*, Briſſ. *Purple martin*, Cateſb. *Purple ſwift*, Arct. Zool. *Purple ſwallow*, Lath.

Length ſeven inches and three quarters; bill black; legs and claws blackiſh; the plumage of the male richly gloſſed with purple, that of the female duſky brown. The ſpecies paſſes the ſummer in Carolina and Virginia, retiring to warmer climates at the approach of winter.

Subis. Blueiſh black; beneath and mouth whitiſh-aſh. Gmel. *Hirundo freti Hudſonis*, Briſſ. *Hirondella de la Baie d'Hudſon*, Buff. *Great American martin*, Edw. *Hudſon's Bay ſwallow.*

Rather larger than the ſwallow; bill black; quills, and forked tail blackiſh edged.

Senegalensis. Shining-black; beneath and rump rufous. Gmel. *Grande hirondelle à ventre roux du Senegal*, Buff. *Senegal ſwallow.*

Length eight inches and a half; the bill black and duſky; rufous on the throat, and under the wings paleſt. Native of Senegal.

Ambrosiaca. Greyiſh brown; bill blackiſh; legs fuſcous. Gmel. *Hirundo riparia ſenegalenſis*, Briſſ. *Hirondelle ambrée*, Buff. *Ambergris ſwallow.*

Size of a wren; the length five inches and a half; bill half an inch long and black; tail very forked; the legs black. According to Seba the ſpecies is ſaid to emit a powerful ſcent, reſembling that of ambergris. The ſpecies inhabits Senegal. There is a variety of this ſpecies, the plumage of which is pale aſh, beneath paler.

Fasciata. Black; tranſverſe band on the belly and ſpot on the outer part of the thighs white. Gmel. *Hirondelle a ceinture blanche*, Buff. *White-bellied ſwallow*, Lath.

Inhabits near rivers in Cayenne and Guiana: the length ſix inches.

TAPERA. Tail-feathers equal; body blackiſh, beneath white. Gmel. *Hirundo Americana*, Briſſ. *Tapera*, Sloane, Marcgr. &c. *Tapere,* Buff. *Tapera ſwallow.*

Length five inches and three quarters; the bill black; throat and breaſt grey brown; quill and tail-feathers blackiſh brown; tail ſlightly forked; legs brown. Briſſon deſcribes the ſpecies as a native of Brazil and Cayenne, and Sloane as an inhabitant of Jamaica, being a bird of paſſage, and remaining on the iſland ſix months of the year.

TORQUATA, Brown, beneath white; tail even; pectoral band brown; between the bill and eyes a white ſpot. Gmel. *Hirondelle brune et blanche à ceinture brune,* Buff. *Brown collared ſwallow.*

Native of the Cape of Good Hope. Length eight inches.

LEUCOPTERA. Cinereous gloſſed with blue and green, beneath, rump, and wings waved with white. Gmel. *Hirondelle à ventre blanc de Cayenne*, Buff. *White-winged ſwallow.*

Length four inches and a half to five inches; the bill black; wings longer than the tail; quill and tail-feathers brown, gloſſed with blue and green; the legs pale. A variety of this ſpecies is alſo found, the plumage of which is brown above, beneath ſpotted with brown. Theſe birds inhabit the marſhes of Savannah.

PELASGIA. Tail-feathers equal, naked and ſubulate at the tip. Gmel. *Hirundo cauda aculeata americana*, Kalm. *Hirundo Carolinenſis*, Briſſ. *American ſwallow*, Cateſby. *Aculeated ſwallow*, Arct. Zool.

There are two diſtinct varieties of this ſpecies, in one of which the throat is whitiſh and ſpotted with rufous, in the other the rump is grey, and the throat grey tinged with rufous. The firſt inhabits Carolina and Virginia, the other Louiſiana; the common occurs in Cayenne. The length is four inches and a quarter, and it builds in chimneys like the common ſwallow.

ACUTA. Black, beneath brown; tail-feathers naked, and ſubulate at the tip. Gmel. *Hirondelle noire acutipenne de la Martinique*, Buff. *Acute tailed ſwallow.*

A ſmall bird not exceeding the ſize of the common wren. This ſpecies is found in Martinique.

PACIFICA. Brown-black; throat and rump blueiſh-white. *L'Hirondelle brune de la Nouvelle Hollande*, Sonn. *Pacific ſwallow.*

Native of the iſlands in the Pacific ocean.

CAUDACUTA. Blackiſh; front white; wing-coverts varied with white; caudal feathers pointed at the end. *Hirundo caudacuta*, Lath. *L'Hirondelle acutipenne de la Nouvelle Galle*, Viel. *Sharp-tailed New Holland ſwallow*

Inhabits New Holland. Size twice that of Hirundo acuta.

DAURICA. Blue, beneath white; temples and rump ferruginous. Gmel. *Hirundo alpeſtris,* Pallas. *Daurian ſwallow.*

Inhabits the Alpine parts of Siberia, and builds an hemiſpherical neſt in the clefts of the higheſt rocks. Its ſize exceeds that of the common ſwallow; the temples are ferruginous; primary quill-feathers blackiſh, the tips obtuſe with a brown ſtreak; the firſt long; outer tail-feather twice the length of the reſt; vent pale-aſh, the feathers black at the tip.

ERYTHROCEPHALA. Duſky black, the feathers edged with white; beneath white; the head red. Gmel. *Red-headed ſwallow,* Lath.

Size of the leaſt humming bird. Inhabits India.

AOONALASHKENSIS. Black; beneath cinereous; rump whitiſh. Lath. *Aoonalaſhka ſwallow.*

Inhabits Aoonalaſhka. Length four inches and a half.

INDICA. Fuſcous, beneath whitiſh; greater part of the head rufous. Gmel. *Rufous-headed ſwallow*, Lath.

Native of India. The length is four inches; ſome of the wing-coverts edged with white; quill-feathers longer than the tail; bill duſky brown; legs duſky.

NIGRA. Entirely black. Gmel. *Hirundo apus dominicenſis*, Briſſ. *Petit martinet noir*, Buff. *Black ſwallow.*

The length of this bird is near ſix inches; the bill black and half an inch long; the tail is forked; and the wings longer by nearly an inch and a half. This ſpecies inhabits dry places in the interior of South America, and is not numerous. For the reception of its neſt it digs a deep hole in the earth, about half a foot in length, with a long entrance riſing to the ſurface, the opening of which is ſo very ſmall as only juſt to permit its entrance. Buffon deſcribes two varieties of this bird, one of which has a white ſtripe in front, and the other entirely blackiſh grey.

DOMINICENSIS. Black, with a ſteel gloſs; abdomen white. Gmel. *Grand martinet noir à ventre blanc,* Buff. *St. Domingo ſwallow.*

Size of the chimney ſwallow; the bill and legs brown. This ſpecies inhabits the Weſt Indian iſlands during the months of May, June, and July. Its ſong reſembles that of the lark.

PERUVIANA. Black, beneath white; band on the belly pale aſh-colour; quill and tail-feathers pale grey, edged with yellowiſh-grey. Gmel. *Hirundo Peruviana major,* Briſſ. *Peruvian ſwallow.*

Native of Peru. The eyes black, ſurrounded by a brown circle.

CINEREA. Black, beneath cinereous; quill and tail-feathers cinereous, edged with yellowiſh-grey. Gmel. *Petit hirondelle noire à ventre cendré,* Buff. *Aſh-bellied ſwallow,* Lath.

Leſs than the common ſwallow, and inhabits Peru and Otaheite. A ſuppoſed variety entirely blackiſh-grey, with the wings longer than the tail, is found in Louiſiana.

CHALYBEA. Black with a ſteel gloſs, beneath white; wings and tail black; bill and legs brown. Gmel. *Hirundo Cayanenſis,* Briſſ. *Hirondelle de Cayenne,* Buff. *Chalybeate ſwallow.*

A conſtant inhabitant of Cayenne throughout the year, and is frequently ſeen perched on fallen or decayed trees, in the hollows of which it lays its eggs, without the trouble of compoſing a neſt. The length of the bird is ſix inches; the bill three quarters of an inch long, rather ſtout, and with the legs brown.

VIOLACEA. Black-blue tinged with violet; greater quill-feathers within, the bill and legs blackiſh. Gmel. *Hirondelle bleue de la Louiſiana,* Buff. *Violet ſwallow.*

Length eight inches and a half; bill three quarters of an inch and black; the legs black. Inhabits Louiſiana.

JAVANICA. Blue-black; front, throat, and fore part of the neck, ferruginous; beneath and rump aſh; tail black, the feathers, except the two middle ones, with a white ſpot each ſide. *Hirundo Javanica,* Sparrman, &c. *Java ſwallow.*

About the ſize of the chimney ſwallow; the bill and legs black. Inhabits Java.

BICOLOR. Black gloſſed with blue; front, fore part of the neck, and flank, red-brown; throat fawn colour. *L'Hirondelle noire et fauve,* Sonnini.

Native of America; ſize of the chimney ſwallow, and rather longer; the wings and tail edged with greyiſh-white; the breaſt grey-brown; middle of the belly and the under coverts of the tail whitiſh ; tail forked ; bill and legs black. The male birds vary in the colour of the plumage, beneath being more or leſs whitiſh, tawny or reddiſh. The colours of the female are more obſcure.

Cærulea. Blue, gloſſed with violet, green, and coppery ; front, cheeks, throat, and under parts of the neck, reddiſh ; tail with a creſcent-formed band of white. *L'Hirondelle bleue et rouſſe*, Sonnini.

A new ſpecies lately found in Guiana ; the length ſix inches and a half ; the bill half an inch ; between the neck and breaſt a blue collar.

** *Toes all placed forwards.* Swift.

Apus. Blackiſh ; chin white. *Hirundo apus*, Linn. *Martinet noir*, and *grand martinet*, Buff. *Mauerſchwalbe*, Friſch. *Black martin* or *ſwift*, Ray. Will. Donov. Br. Birds.

The male of this well known ſpecies is about eight inches long, the female rather leſs ; the whole plumage of the former ſooty black, except the chin, that of the female more inclining to brown, and the ſpot on the chin obſcure. The ſwift, from its length of wing, flies well, but its feet are ſo ſmall that it riſes from the ground with great difficulty ; its walking alſo is attended with inconvenience from the ſame cauſe, and it reſts chiefly by clinging to the ſides of walls, and other ſimilar ſituations. It builds under the eaves of houſes, or in ſteeples, towers, and other lofty buildings ; and generally lays five eggs, the colour of which is white, and the form ſomewhat elongated. The food of theſe birds conſiſts of inſects. They are inhabitants chiefly of the European continent, though ſometimes noticed in America. This is the only kind of ſwift found in Britain.

Melba. Brown ; chin and belly white. *Hirundo melba*, Gmel. *Hirundo major Hiſpanica*, Briſſ. *Hirundo riparia maxima*, Klein. *Hirundo Alpina*, Scop. *Grand martinet à ventre blanc*, Buff. *Greateſt martin* or *ſwift*, Edw. *White bellied ſwift.*

Length eight inches and a half ; the bill black ; collar grey-brown varied with blackiſh ; wings and tail gloſſed with red and green ; breaſt white ; lower part of the belly grey-brown ; legs fleſh-colour, and downy in front. Inhabits the mountainous parts of Spain, and other countries in the ſouth of Europe. It flies higher than the common ſwift, and, like that ſpecies, feeds on inſects.

Cayennensis. Blackiſh-violet ; head black ; collar two-cleft, band of the eyes, and the thighs white. Gmel. *Martinet à collier blanc*, Buff. *White collared ſwift.*

Native of Cayenne, where it builds its neſt in houſes. The neſt is large, long, and conic, the greateſt breadth five inches, and the length nine inches ; it is compoſed of down well woven together, and the cavity divided obliquely down the middle by a partition which extends over that part of the neſt in which the eggs are diſpoſed. The length of this bird is five inches and a quarter.

Sinensis. Brown, beneath reddiſh grey ; crown pale rufous ; eye-brows brown ; chin and eye-lids white. Gmel. *Grand martinet de la Chine*, Sonner. *Chineſe ſwift.*

Inhabits China ; length eleven inches and a half ; bill, irides, and legs blue-grey.

HIRZHOLMEN, or Hertzholm, in *Geography*, three ſmall iſlands of Denmark, lying in the Cattegat, chiefly inhabited by fiſhermen ; 4 miles N.E. of Fladſtrand. N. lat. 57° 31′. E. long. 10° 24′.

HISCAR Chaduman, or *Hiſaree*, a town of Great Bucharia ; 60 miles N.N.E. of Balk.

HISCHERE, two ſmall iſlands among the Hebrides. N. lat. 57° 37′. W. long. 7° 40′.

HISHOLT, a town of Sweden, in the province of Smaland ; 20 miles S.E. of Helmſtadt.

HISINGEN, a ſmall iſland in the North ſea, ſituated near the coaſt of Sweden, at the mouth of the Gotha, about 16 miles long and ſix broad, containing ſeven pariſhes. The town of Gotheborg was firſt built on this iſland. N. lat. 57° 45′. E. long. 11° 48′.

HISMO, a town of Albania, at the mouth of a river ; 16 miles N.N.E. of Durazzo.

HISPA, in *Entomology*, a genus of Coleoptera in the Linnæan ſyſtem, having the antennæ cylindrical, approximate at the baſe, and ſeated between the eyes ; feelers fuſiform ; thorax and wing-caſes often ſpinous, and uſually toothed at the apex.

The four ſpecies of the hiſpa tribe, known to Linnæus, were atra, teſtacea, ſanguinicollis, and mutica, the laſt of which was not however then conſidered as appertaining to that genus, being referred by Linnæus to the dermeſtes family, under the ſpecific name of clavicornis. Geoffroy deſcribes the ſpecies atra as a native of France, and this he places with his *crioceres*, the genus formed by that writer of the oblong chryſomelæ ; but from which, on cloſe inſpection, the true hiſpæ will be found to differ rather conſiderably in the ſtructure of the antennæ, and ſome other leſs eſſential particulars. No material progreſs was made in the knowledge of the ſpecies compoſing the hiſpa genus till the time of Fabricius, that writer having deſcribed and brought together in one view, from the cabinets of Rohr, Boſc, Paykull, and Hunter, no leſs than 12 ſpecies, including the four already mentioned. In the firſt inſtance Fabricius included more, ſeveral new kinds being united by him with the true hiſpæ, which, on mature deliberation, he conceived it proper to ſeparate, and divide into two new genera ; and thus it happens, that the *Ptilinus* and *Melaſis* of his laſt works are hiſpæ of the former. This obſervation will ſerve to explain, in an obvious manner, the cauſe of that diſcordance which prevails between the works laſt noticed, and the Gmelinian edition of the Syſtema Naturæ ; the latter containing, under the genus hiſpa, a further number of Fabrician ſpecies, than the "Entomologiæ Syſtematicæ" of that author, or any of his later works, in which Ptilinus and Melaſis are conſidered ſeparately. Thunberg has added ſome new ſpecies to the hiſpæ tribe, and theſe augmentations have increaſed the number to nearly twenty ſpecies.

The genuine hiſpæ, according to Fabricius, have cylindrical antennæ ; feelers equal, filiform, and thicker in the middle ; jaws bifid, and lip horny and entire. *Ptilinus* has the antennæ flabelliform ; feelers four, and ſomewhat equal ; jaws ſhort and bifid ; and the lip membranaceous and ſubemarginate. In *Melaſis* the antennæ are flabelliform, as in Ptilinus, but the feelers (four in number) are clavated, with the extreme joint ovate, and the lip membranaceous and entire.

Moſt of the hiſpa genus are natives of extra European climates ; thoſe found in Europe occur in the winged ſtate on the leaves and roots of different kinds of graſs ; their larvæ and transformations are unknown.

Species.

Atra. Antennæ fuſiform ; thorax and wing-caſes ſpinous. Linn. *Crioceris tota atra*, Geoff.

Found at the roots of graſs in Europe.

Testacea. Antennæ fuſiform ; body teſtaceous ; antennæ and eyes black. Linn.

An African ſpecies ; ſpines on the thorax lateral, on the wing-caſes ſcattered, the whole black.

Bifustulata. Antennæ ſerrated; body hairy, and black; wing-caſes with a rufous ſpot at the baſe. Fabr.

Native of Italy.

Mutica. Antennæ hairy; body black; wing-caſes ſtriated. Linn.

Inhabits Europe.

Sanguinicollis. Antennæ fuſiform; thorax and baſe of the wing-caſes ſanguineous; wing-caſes ſerrated. Linn.

An American ſpecies; wing-caſes ſerrated at the tip with three elevated ſtriæ, and the intermediate ſpaces punctured.

Serrata. Antennæ fuſiform; body black; wing-caſes pale rufous, ſerrated and black at the tip. Fabr.

Native of Surinam; thorax black with rufous ſides; wing-caſes ſtriated.

Dentata. Antennæ fuſiform; body black; margin of the thorax yellow; wing-caſes ſerrated, with a yellow ſpot at the baſe, and a band in the middle. Fabr.

Head, with the antennæ black; thorax black except the ſides; breaſt and baſe of the abdomen yellow. Inhabits Cayenne.

Angulata. Antennæ fuſiform; body yellow; head, dorſal line on the thorax, and ſinuate margin of the wing-caſes black. Fabr.

Native of Cayenne. Head and antennæ black; wing-caſes grooved, truncated, and toothed at the tip; body beneath ferruginous.

Emarginata. Antennæ fuſiform; body black; wing-caſes with a rufous ſpot at the baſe, the tip bidentated. Fabr.

Size of the preceding; head rufous; eyes globular, and with the antennæ black; wing-caſes with three raiſed lines, tranſverſely grooved; body beneath paliſh; legs black; thighs pale at the baſe. Inhabits Surinam.

Serraticornis. Antennæ ſerrated, and compreſſed at the baſe; body black; margin of the thorax, and ſpot at the baſe of the wing-caſes yellow. Fabr.

Inhabits Surinam, and reſembles the laſt. The head is whitiſh; crown black; wing-caſes grooved, with a ſingle raiſed line in the middle, and three-toothed at the tip, the middle tooth larger, rounded, and ſerrated; breaſt and baſe of the thighs white.

Bidens. Ferruginous; thorax with a black lateral line; tip of each wing-caſe armed with a ſingle tooth. Fabr.

Size of the laſt; head ferruginous; eyes black; wing-caſes grooved with a double row of dots between each furrow. Native of Surinam.

Nigricornis. Glabrous and ſcarlet; antennæ black. Fabr.

Native of the Cape of Good Hope.

Bihamata. Unarmed, black, ſpotted with red; wing-caſes truncated and hooked. Gmel.

Oblong, depreſſed, and inhabits India.

Cornuta. Entirely black; anterior and poſterior part of the thorax ſpinous; wing-caſes with longitudinal raiſed lines. Thunb.

Inhabits Sweden.

Capensis. Pitchy and hiſpid; thorax with a palmated ſpine. Thunb.

Found at the Cape of Good Hope.

Scabra. Entirely black; thorax and wing-caſes with a ſerrated fringe at the edge. Thunb.

Inhabits Sweden.

Serratula. Brown; antennæ ſerrated; wing-caſes ſtriated. Thunb.

Inhabits Upſal.

HISPALIS, Seville, in *Ancient Geography*, a town of Hiſpania, on the Bœtis, which was one of the moſt conſiderable towns in Bœtica. This city was ancient even in the time of Strabo, Pomponius Mela, Pliny, and Ptolemy, all of whom have mentioned it. Its foundation has been attributed to Hercules, to Bacchus, to the Hebrews, the Chaldeans, and the Phœnicians. When it became a Roman colony, it was much frequented on account of its commerce. It had the ſurname of Romulenſis and the title of Conventus. The changing of the name Hiſpalis, which ſome aſcribe to a prince of that name, but which is more probably derived from Spila, or Spala, a Phœnician word ſignifying a plain, or verdant country, into that of Colonia Romula, which it bears on its medals, is aſcribed to Julius Cæſar by Iſidore. Julius Cæſar, according to him, founded Hiſpalis; and from his name, joined to that of Rome, it was denominated Julia Romula. Many of the medals of this town exhibit traces of the baſeſt adulation with regard to Auguſtus; as his head is adorned with the attributes of the ſovereign of univerſal nature. Thoſe of Julius are of a ſimilar kind. On ſome Tiberius appears on one ſide, and on the other Germanicus and Druſus, whom he had adopted. See Seville.

HISPANIA, in *Ancient Geography*, an extenſive country, forming a kind of peninſula in the S.W. of Europe, and comprehending Hiſpania Tarragonnenſis, Luſitania, and Bœtica. It lay between 36° and 43° 46′ 37″ N. lat., and between 8° and 21° E. long. from Ferro. It was bounded on the N. by the bay of Biſcay and the Pyrenean mountains; on the E. and S. by the Mediterranean ſea; and on the W. by the Atlantic ocean. The greateſt breadth of this peninſula, from N. to S., is 550 miles, and its length 660 on the parallel of 42° N. lat. Spain, or a conſiderable part of it, was anciently called *Iberia*, (which ſee,) and *Celtiberia*, (which ſee,) from the Celtæ and Iberi, two tribes of barbarians ſettled on the banks of the Ebro (ſee Celtiberians); Heſperia, from its ſituation, being the weſtern province of the Roman empire, of Europe, and of the Continent; and alſo Hiſpania, probably from the oriental שָׁפָן, "Span," or "Sphan," concerning the meaning of which there is ſome difference of opinion. Bochart ſays that Span ſignifies a rabbit, and that this name was given to the country becauſe it was found to abound with theſe animals. Others, however, allege, that the proper ſignification of the oriental Span is ſomething concealed, or far from view; and ſuch, it is alleged, was the ſituation of Hiſpania with regard to the Phœnicians. Moreover, as the northern region was remote and concealed with regard to the ſouth, Span was uſed to denote the north. This appellation, it is ſaid, was given to it by the Phœnicians, as a remote or concealed country with reſpect to the farther extremity of the Mediterranean; and as they approached it along the coaſt of Africa and towards the ſtrait, they alſo might juſtly call it, with regard to themſelves, the northern country. Before the Carthaginians made any conqueſts in Spain, the country muſt have been divided into various petty independent kingdoms; and during this early period, the Phœnicians, who were probably the firſt people who came hither by ſea, planted ſeveral colonies along the ſouthern coaſts, in Turditania, a diſtrict of Bœtica; and afterwards ſome Grecian adventurers from Marſeilles croſſed the gulf of Lyons, and ſettled near the N.E. extremity of the country. After the Carthaginians had ſubjected it to their dominion, it was partitioned into provinces, the number of which cannot now be aſcertained. However, they eſtabliſhed colonies on the ſouth coaſt, E. of the ſtrait of Gibraltar. The firſt diviſion which the Romans made of that part which they reduced, was into Hiſpania Citerior and Hiſpania Ulterior, which were governed ſometimes by prætors, and ſometimes by proconſuls. This diviſion took place, as Livy informs us, immediately after the concluſion of the ſecond Punic war. In the beginning of the Macedonian war, the two provinces were united; but they were again ſeparated in the conſulate of Q. Ælius Pætus and M. Junius Pennus. This laſt diſtribution of Spain continued till the reign of Auguſtus, who divided Hiſpania Ulterior into the two provinces of Bœtica and Luſitania, and affixed the name of Provincia Tarraconenſis to Hiſpania Citerior. This latter province, ſo called from its principal city, comprehended nearly three-fourths of modern Spain, and was ſeparated from Bœtica and Luſitania by an imaginary line ſuppoſed to extend from the gulf of Carthagena to the conflux of the Agueda and Douro, on the confines of Portugal. Bœtica, ſo called from the river Bœtis, was a ſmall province along the coaſt, on either ſide of Fretum Herculeum, from the gulf of Carthagena to the mouth of the Anas; and, in general, included the provinces now called Granada and Andaluſia. The diviſion, introduced by Auguſtus, remained as long as the Romans had any power in Spain. (See BŒTICA, LUSITANIA, and TARRACONENSIS.) The moſt noted rivers in Hiſpania were the Minius or Minho, Lethe or Lima, Durius or Douro, Tagus or Tajo, Anas or Guadiana, Bœtis or Tarteſſus or Guadalquivir, Singulis or Xenil, Terebus or Tader or Segura, Sucro or Xucar, Iberus or Ebro, Sicoris or Segre, Rubricatus or Lobregat, Sambroca or Ter; and its principal bays were the Sucronenſis ſinus or bay of Valencia, Illicitanus ſinus or bay of Alicant, Virgitanus ſinus or gulf of Carthagena, Gaditanus ſinus or bay of Gibraltar, Magnus Portus or bay of Corunna, commonly called the Groine, and Cantabricus ſinus or bay of Biſcay. Its chief mountains, capes and promontories, as well as towns, will appear under their proper heads, and under the title SPAIN.

As to the hiſtory of Hiſpania, it is hardly neceſſary to obſerve, that the Spaniards trace their origin from Tubal, the fifth ſon of Japhet, who is ſaid to have reigned in Spain from the year of the flood 143 to 258; and that from him they pretend to give a ſeries of monarchs down to three Geryons, who were killed by the Egyptian Hercules, and of ſome other invaders from Libya, as far as the time in which they allow the Celtes to have made their firſt entrance into Spain, in the year of the flood 1350. According to this fabulous account, Spain had been a monarchy, and had laſted 1226 years before the arrival of the Celtes. But diſmiſſing theſe fables, we ſhall begin the hiſtory of Spain with the arrival of the Celtes in this country, which is ſaid to have taken place in the year 1649 B.C. Theſe people croſſed the Pyrenees, and after a conteſt with the Iberians, as the native Spaniards were called, formed an alliance with them, and by intermarriage they became one people, under the name of Celtiberians. After an interval of about 20 years, the Rhodians came hither by ſea, and ſettling at the foot of the Pyrenean mountains, built a city, to which they gave their name; but which has long ſince been reduced to ruins. At this time the mines of Spain yielded great quantities of ſilver; acccordingly Ariſtotle informs us, that the Phœnicians viſited this country in the 9th century B.C. to exchange their naval commodities for this metal; and they are ſuppoſed to have ſettled in Bœtica and to have built ſeveral cities. Euſebius, in his Chronicon, ſub Ann ante Chr. 840, mentions ſeveral nations, beſides Tyrians, Egyptians, and Phœnicians, who made ſettlements in Spain; ſuch were the Mileſians, Cariti or Carians, Leſbians, and Phocians. Nebuchadnezzar alſo, after the deſtruction of Jeruſalem and conqueſt of Judea, is ſaid, by Joſephus and Strabo, to have reigned in Spain nine years; at the end of which period, it is affirmed, that he abandoned it to the Carthaginians. (See CARTHAGINIANS.) It is probable, however, that moſt, if not all, of theſe nations, contented themſelves with maritime ſituations, for the advantage of commerce and the command of the ſea; and that they penetrated but a little way into the country; while the natives might enjoy their own laws and government, and be glad to trade and barter with them, and feel little ſolicitude who were maſters of the ſea-coaſts and parts adjacent, provided they could obtain the benefits of commerce with them, and enjoy the produce of their own lands, in peace and tranquillity. The Carthaginians, after many ſevere conteſts with the Romans, were diſpoſſeſſed by the Scipios, and as ſoon as they became maſters of this rich and productive country, or at leaſt of a conſiderable part of it, they directed their chief attention to its valuable mines, particularly thoſe of ſilver and gold; and it is ſaid, that Scipio, upon his return to Rome, carried with him 14,342 pounds of ſilver, beſides an immenſe quantity of coin, cloaths, corn, arms, and other valuable effects. L. Lentulus is ſaid to have brought away 44,000 pounds of ſilver, and 2550 pounds of gold, beſides the money which he diſtributed among his military followers. L. Manlius carried with him 1200 pounds of ſilver, and about 30 of gold. Corn. Lentulus, after having governed the Hither Spain two years, poſſeſſed himſelf of 1515 pounds of gold, and of ſilver 2000, beſides 34,550 denarii in coin, whilſt his colleague brought from Further Spain 50,000 pounds of ſilver. It was this prodigious wealth, ſupplied by the country, which was ſtill thought to be unexhauſted, that invited the northern nations many centuries after, to make incurſions, and to drive the Romans out of it. (See GOTHS and VANDALS.) Learning, and the liberal arts, if Strabo (lib. iii.) may be credited, began to flouriſh at an early period in this country; for he tells us, that the Turdetani, a people of Bœtica, were very celebrated in this reſpect, and were poſſeſſed of a vaſt number of volumes of great antiquity, and codes of laws written in verſe, and other pieces of poetry of very ancient date. Their language was moſt probably the old Celtic; but it underwent many changes by means of the different nations who ſubdued this country, and particularly by the influence of the Romans. Upon the irruption of the Goths and Vandals, it degenerated from its purity. It is evident, if we may depend upon the authority of Strabo, that the ancient Spaniards muſt have admitted writing many ages before the Gauls, Germans, or any others of Celtic extraction. From the ſettlement of the Romans, however, their letters, as well as language, extirpated all the reſt, and continued in uſe till their expulſion, when the old Gothic took place. In the educating of their youth, they took great pains to inſpire them with a love of liberty, and a contempt of death. This country, by reaſon of its excellent ſituation for commerce, and the abundance of commodities, particularly ſilver, which it furniſhed, invited thither all the trading nations of Europe, Aſia, and Africa; nor is there, perhaps, any kingdom, that ever paſſed under ſo many different maſters. Egyptians, Phœnicians, Tyrians, Carthaginians, Romans, Gauls, Germans, Goths, Vandals, Moors, and many others had their ſettlements in it, and thus promoted its trade and navigation, and founded in it great and opulent cities. With regard to the character of the ancient Spaniards, we may obſerve, that they poſſeſſed all the virtues of the old Celtic nation; and inherited fewer of their vices than any others of their deſcendants; they were brave, magnanimous, and hoſpitable to a high degree; and ſo famed for their fidelity, that even after being conquered by the Romans, ſeveral of theſe emperors preferred them to other nations, to be their body-guard. They were ſober, frugal, and patient under hardſhips; jealous of their honour, and till a few centuries paſt, rather deſirous to preſerve their own territories, than to ſeek new ſettlements abroad. See Spain.

HISPANICUM Viride, *Spaniſh green*, a name given by ſome to verdigris.

HISPANIOLA, in *Geography*. See *St.* Domingo.

HISPID Leaf, among *Botaniſts*. See Leaf.

Hispid *Stalk*. See Stalk.

HISSAR, in *Geography*, a circar of Hindooſtan, in the Soubah of Delhi, bounded on the N. by Sirhind, on the E. by Ballogiſtan, on the S. by Nardeck, and on the W. by Moultan.

Hissar *Ferozeh*, the capital of the above circar, near the river Surſooty, which traverſes the circar from N. to S.; 75 miles W. of Delhi. N. lat. 28° 40′. E. long. 76° 4′.

HISSING, an appellation given by grammarians to the three conſonants, *s*, *x*, and *z*.

HISTER, an Etrurian word which implied a ſtage-player, and during the peſtilence at Rome, 364 years B.C. actors were ſent for from Etruria, to try to appeaſe the gods by public exhibitions; hence the Roman actors afterwards acquired the name of hiſtriones. Livy, lib. vii. cap. 2.

Hister, in *Entomology*, a genus of Coleoptera, the antennæ of which are clavated, and the club ſolid, with the laſt joint compreſſed and decurved; head retractile within the body; mouth forcipated; wing-caſes ſhorter than the body, and truncated; anterior ſhanks toothed; hind ſhanks ſpinous. In the larvæ, as well as the adult, or winged ſtate, the inſects of this family are frequently met with in the dung of horſes, cows, and other animals.

Species.

Major. Black; wing-caſes ſomewhat ſtriated; thorax ciliated at the edges. Linn.

Native of Africa, and differs only in ſize from the Linnæan hiſter maximus. The hairs at the edges of the thorax ferruginous.

Unicolor. Black; wing-caſes obliquely ſtriated. Linn. Donov. Br. Inſ.

Inhabits Europe and America.

Glabratus. Black and poliſhed; wing-caſes ſomewhat ſtriated, punctured, and as long as the abdomen. Fabr.

Jaws advanced, arched, acute and armed with a tooth in the middle; antennæ black; wing-caſes retuſe behind.

Semipunctatus. Black, poliſhed, braſſy; wing-caſes obliquely ſtriated at the baſe, and obſoletely punctured at the tip. Herbſt.

Native of Barbary; head and thorax with a braſſy hue; all the ſhanks compreſſed and ſerrated. Found alſo by Paykull in Sweden; and by Marſham in Britain.

Scaber. Black, and ſcabrous, with raiſed dots. Fabr. Inhabits Spain.

Cyaneus. Thorax braſſy; wing-caſes blueiſh. Oliv.

A New Holland ſpecies; the head duſky; thorax ſomewhat punctured at the margin; wing-caſes poliſhed, abbreviated, and obliquely ſtriated at the baſe; legs black.

Planus. Plane opaque and black; wing-caſes very ſmooth. Fueſly, &c.

Native of the ſouth of Europe.

Brunneus. Ferruginous; wing-caſes ſub-ſtriated. Oliv.

Inhabits Sweden; and alſo Britain (Donov. Br. Inſ.)

Pygmæus. Deep black; wing-caſes very ſmooth. Linn.

Inhabits Europe.

Depressus. Depreſſed, black, and poliſhed; wing-caſes ſomewhat ſtriated. Oliv. *Hiſter compreſſus*, Herbſt.

Found under the bark of birch-trees in Germany (Panz), and in Britain (Donov. Br. Inſ.).

4-Dentatus. Depreſſed, black, and poliſhed; wing-caſes with a ſingle ſtripe; jaws exſerted, and longer than the head. Oliv.

Native of North America.

Sulcatus. Black; thorax with five raiſed lines, wing-caſes three; the interſtices punctured. Oliv.

Inhabits Europe. Small; the head rather prominent each ſide above the eyes; anterior legs toothed.

Duodecim striatus. Black, poliſhed; wing-caſes with twelve ſtriæ. Marſh, &c.

Found in France (Vill.), in Sweden (Paykull), and in England (Donov. Br. Inſ.).

Violaceus. Violaceous; thorax entirely dotted; wing-caſes with five recurved ſtriæ at the baſe, tip dotted. Marſh.

Inhabits Britain. Length two lines and three quarters.

Virescens. Green; thorax entirely dotted; wing-caſes with four recurved ſtriæ, the tip dotted. Marſh.

Perhaps a ſmall variety of hiſter violaceus; the length one line and a half.

Piceus. Entirely pitchy; wing-caſes length of the abdomen, with four ſtriæ. Marſh.

Native of Britain; length one line.

Oblongus. Depreſſed, black, and poliſhed; wing-caſes ſtriated; body oblong. Fabr.

Inhabits Sweden, under the bark of the roots of the aſh. Afzelius. Differs from H. ſulcatus in the more oblong form of the body.

Abbreviatus. Black; wing-caſes with crenated ſtriæ, the inner ones abbreviated.

Native of America. Size of H. pygmæus.

Sinuatus. Black, with a ſinuate rufous ſpot in the middle of the wing-caſes. Fabr. *Hiſter reniformis*, Oliv.

Wing-caſes ſtriated at the inner edge, and ſmooth at the future. Inhabits Germany.

Cruciatus. Black; wing-caſes teſtaceous, with a common black croſs. Fabr.

Native of Barbary. Wing-caſes ſmooth and poliſhed, the ſuture and ſpot croſſing it in the middle black; hind margin black. Fabr.

2-Maculatus. Black; wing-caſes ſtriated with a red ſpot behind. Donov. Br. Inſ.

Inhabits Europe.

4-Maculatus. Black; wing-caſes with two red ſpots on each. Oliv.

Native of Germany (Panz), alſo found in Britain (Donov. Br. Inſ.)

Æneus. Braſſy; wing-caſes ſtriated at the baſe, and punctured at the tip. Fabr. *Attelabus cupreus*, Fourcr.

Inhabits Sweden (Paykull), and Britain (Donov. Br. Inſ.)

Detritus. Black, poliſhed; wing-caſes pitchy, with duſky tip. Oliv.

Wing-caſes with four oblique ſtriæ at the baſe, the tip punctured. A New Holland ſpecies.

Picipes. Oblong and black; wing-caſes very ſhort; antennæ and legs pitchy. Oliv.

Inhabits Germany. Wing-caſes abbreviated and not ſtriated.

Cæsus. Black; thorax with a tranſverſe groove; antennæ ferruginous. Herbſt.

Native of Germany.

Parvus. Uniform black; wing-caſes with ſix ſtriæ; two inner ſtriæ abbreviated. Marſh.

A new ſpecies found in Britain.

Inæqualis. Black, poliſhed; wing-caſes ſtriated exteriorly, towards the ſuture ſmooth; jaws longer than the head. Fabr. Supp. *Hiſter lævis*, Roſſi.

Inhabits Germany, and alſo England. Donov. Br. Inſ.

Quadriguttatus. Black, poliſhed, and very ſmooth, wing-caſes dotted, with two pale yellowiſh ſpots on each. Fabr.

Lately diſcovered in Pembrokeſhire. Donov. Tour Wales. Spots on the wing-caſes whitiſh or reddiſh.

Bipustulatus. Black, with a red ſpot in the middle of each wing-caſe; anterior ſhanks tridentated. Schrank, &c. *Hiſter purpuraſcens*, Paykull.

Length two lines and a half; the ſpecies inhabits Sweden (Paykull), Germany (Panz), and Bohemia (Preys).

Obſ. This inſect muſt not be confounded with the hiſter bipuſtulatus of the Fabrician Suppl. a ſpecies twice the ſize of bimaculatus, and which inhabits India. The colour of this laſt-mentioned kind is deep black; wing-caſes ſtriated, with a red dot in the middle, and the head retuſe.

Impressus. Deep black and poliſhed; wing-caſes ſtriated; head with two impreſſed dots.

Size of hiſter unicolor, but diſtinct in having the two impreſſed dots in front of the head; all the ſhanks ſerrated. Inhabits Kiel.

Pulchellus. Braſſy-green; wing-caſes ſtriated, with a rufous dot behind; vent coppery. Fabr. Suppl.

Small, and inhabits Tranquebar; head and thorax braſſy-green, poliſhed and immaculate; vent prominent.

Erythropterus. Deep black and poliſhed; wing-caſes ſtriated, with the tip rufous. Oliv.

Native of Tranquebar. Allied to hiſter bipuſtulatus.

Perpusillus. Rufous brown, and dotted. Marſh.

Length one-third of a line, and inhabits Britain. The form convex, dots not conſpicuous without a lens.

Minimus. Black, very glabrous and poliſhed. Marſh.

Scarcely ſo large as the laſt; country the ſame.

HISTIÆA, in *Ancient Geography*, *Orio*, a maritime town of the iſland of Eubœa, under mount Telethrius, near the mouth of the river Callas. It was ſituated on a rock, and therefore called Oreum.

HISTIÆOTIS, a country of Theſſaly, ſituated under mount Oſſa and mount Olympus, the latter lying to the N. and the former to the S. This country was alſo called the "Doride," from Dorus, the ſon of Deucalion, under whoſe reign it was inhabited by a Pelaſgic nation, which was driven from it by the Cadmæans. But, in proceſs of time, the Perrhæbi, having deſtroyed the town of Hiſtiæa in the iſle of Eubœa, cauſed its inhabitants to remove to the continent, who gave to the territory which they occupied, the name of Eſtiæotide, according to Strabo, but according to Herodotus, Hiſtiæotide.—Alſo, a ſmall country in the iſland of Eubœa, of which Hiſtiæa was the capital, and which extended to Artemiſium, towards the Canæum promontorium, at a little diſtance from Thermopyla.

HISTIODROMIA, the art of ſailing, or of conducting veſſels on the ſea.

The word is compounded of ἱστιον, *ſail*, of ἱστος, the *maſt of a ſhip*, which comes from ἱστημι, *ſto*, *I ſtand*, and δρομος, *courſe*, of δρεμω, *I run*.

Hiſtiodromia is the ſame with what we otherwiſe call *navigation*.

Hiſtiodromia turns on four points, any two whereof being given, the other two are eaſily found from them, by the loxodromic tables, ſines, tangents, ſecants, Mercator's charts, &c. Theſe four things are, the difference of latitude, difference of longitude, the courſe, and the diſtance run.

HISTORICAL, ſomething that relates to hiſtory.

Historical *Column*. See Column, *hiſtorical*.

Historical *Muſic*, *muſica hiſtorica*, is that branch of muſic which treats of the origin and invention of muſic, of modes, of notes, inſtruments, &c. as alſo the lives and writing of celebrated authors on that ſubject.

Historical *Painting*. The derivation of the word hiſtorical, at once points out the proper application of it as deſcriptive of one particular application of the art of painting, (*i. e.*) the repeſentation of events which have occurred, and which are fit ſubjects for the pen of the hiſtorian; but common cuſtom applies it in a more extended, though very improper, ſenſe, as deſcriptive, not only of what is ſtrictly hiſtoric, but what is alſo of the *poetic* or dramatic nature: and divides the laſt into four branches only, which are Hiſtorical, Portraiture, Landſcape, and Still-life. See Painting.

Historical *Style*. See Style.

HISTORIOGRAPHER, compoſed of ἱστορια, *hiſtory*, and γραφω, *I write*, a profeſſed hiſtorian, or writer of hiſtory; or a perſon who applies himſelf peculiarly to it.

The province of the hiſtorian is important and extenſive; and he, therefore, ought to be endowed with great and uncommon qualifications. As it is the office of the hiſtorian to record truth for the inſtruction of mankind, impartiality, fidelity, gravity, dignity, and accuracy are indiſpenſible and eſſential qualities belonging to a perſon who undertakes this office. He muſt neither be a panegyriſt nor a ſatyriſt. He muſt not enter into faction, nor give ſcope to affection: but contemplating paſt events and characters with a cool and diſpaſſionate eye, muſt preſent to his readers a faithful copy of human nature. Cicero has given us the whole art of compoſing hiſtory in a very compendious and comprehenſive manner. No one is ignorant, ſays he, that the firſt law in writing hiſtory is, not to dare to ſay any thing that is falſe, and the next, not to be afraid to ſpeak the truth; that on the one hand there be no ſuſpicion of affection, nor of prejudice on the other. Theſe fundamental principles are generally known: but the ſuperſtructure conſiſts partly in things and partly in the ſtyle or language. The former require an order of time, and deſcription of places. And becauſe in great and memorable events, we are deſirous to know firſt their cauſes, then the actions themſelves, and laſtly their conſequences; the hiſtorian ſhould take notice of the ſprings or motives that occaſioned them; and in mentioning the facts themſelves ſhould not only relate what was done or ſaid, but likewiſe in what manner; and in treating of their conſequences, ſhew whether they were the effects of chance, wiſdom, or prudence. Nor ſhould he only recite the actions of great and eminent perſons, but likewiſe deſcribe their characters. The ſtyle ought to be fluent, ſmooth, and even, free from that harſhneſs and poignancy which are uſual at the bar. De Orat. lib. ii. cap. 15.

According to this plan, in the obſervance of which few are ſuperior to Tacitus, an hiſtorian ſhould be not only a man of probity, but free from all paſſion and bias: he ought to unite the ſteadineſs of a philoſopher with the vivacity of a poet or orator. He ſhould alſo poſſeſs a good judgment, to direct him what is proper to be ſaid, and what to be omitted, and to treat every thing in a manner ſuited to its importance. This faculty will enable him to ſelect ſuch facts as are of the greateſt moment; to repreſent them in connection with their cauſes, to trace them to their conſequences and effects, and to unfold them in clear and diſtinct order. Wiſdom is the great end of hiſtory. It is deſigned to ſupply the want of experience; and though it does not enforce its inſtructions with the ſame authority, yet it furniſhes a greater variety of inſtructions than it is poſſible for experience to afford in the longeſt life. Its object is to enlarge our views of the human character, and to give full exerciſe to our judgment on human affairs. It muſt not, therefore, be a tale calculated merely to pleaſe, and addreſſed to the fancy. Gravity and dignity are eſſential characteriſtics of hiſtory; no light ornaments are to be employed, no ſlippery of ſtyle, no quaintneſs of wit. But the writer muſt ſuſtain the character of a wiſe man, writing for the inſtruction of poſterity; one who has ſtudied to inform himſelf well, who has pondered his ſubject with care, and addreſſes himſelf to our judgment rather than to our imagination. At the ſame time, hiſtorical writing is by no means inconſiſtent with ornamented and ſpirited narration. It admits of much high ornament and elegance; but the ornaments muſt be always conſiſtent with dignity; they ſhould not appear to be ſought after; but to riſe naturally from a mind animated by the events which it records.

Induſtry is likewiſe an eſſential quality of an accurate hiſtorian. Thucydides in his Hiſtory of the Peloponneſian War, and Polybius in his Hiſtory of the Roman Affairs, took great pains in procuring neceſſary information. An hiſtorian ſhould be always actuated by a love of truth; to this purpoſe Polybius obſerves, that a good man ought to love his friends and his country, and manifeſt a ſimilar diſpoſition with their's, towards both their friends and enemies. But when he takes upon him the character of an hiſtorian, they muſt all be forgot. In hiſtory, all perſonal conſiderations ſhould be laid aſide, and regard be paid only to their actions. Lib. i. p. 13. See alſo Lucian, De Hiſt. Scrib. p. 366.

Suetonius, Thucydides, and Polybius are much commended for the integrity and ingenuity of their temper. Cicero obſerves, (ubi ſupra,) that hiſtory is converſant in great and memorable actions; and therefore a hiſtorian ſhould always keep poſterity in view, and relate nothing which may not on ſome account or other be worth the notice of future ages. Thoſe who deſcend to trivial and minute matters, which are below the dignity of hiſtory, ſhould be deemed journaliſts rather than hiſtorians. Whenever a prudent hiſtorian thinks it neceſſary or convenient to take notice of things that are in themſelves leſs conſiderable, he either does it with brevity, or for ſome apparent reaſon, or accounts for it by ſome juſt apology. As it is the province of a hiſtorian to acquaint us with facts, he ſhould give a narration or deſcription not only of the facts, or actions themſelves, but likewiſe of ſuch things as are neceſſarily connected with them, *viz.* the characters of perſons, the circumſtances of time and place, in reference to which chronology and geography have been called the two eyes of hiſtory; the views and deſign of the principal actors, and the iſſue and event of the actions which he deſcribes. The proper diſpoſition of theſe various particulars depends on the ſkill and prudence of the writer.

The drawing of characters, ſays Blair, is one of the moſt ſplendid, and at the ſame time, one of the moſt difficult ornaments of hiſtorical compoſition. For characters are generally conſidered as profeſſed exhibitions of fine writing: and an hiſtorian, who ſeeks to ſhine in them, is frequently in danger of carrying refinement to exceſs, from a deſire of appearing very profound and penetrating. He brings together ſo many contraſts, and ſubtle oppoſitions of qualities, that we are rather dazzled with ſparkling expreſſions, than entertained with any clear conception of a human character. A writer who would characteriſe in an inſtructive and maſterly manner, ſhould be ſimple in his ſtyle, and ſhould avoid all quaintneſs and affectation: at the ſame time not contenting himſelf with giving general outlines only, but deſcending into thoſe peculiarities which mark a character in its moſt ſtrong and diſtinctive features. The Greek hiſtorians ſometimes give elogiums, but rarely draw full and profeſſed characters. The two ancient authors, who have laboured this part of hiſtorical compoſition moſt, are Salluſt and Tacitus. In tracing actions and events which the hiſtorian records to their ſprings, and alſo to their effects and conſequences, two qualifications are neceſſary in order to his doing this with ſucceſs: *viz.* a thorough acquaintance with human nature, and political knowledge, or acquaintance with government. The former is neceſſary to account for the conduct of individuals, and to give juſt views of their character: the latter to account for the revolutions of government, and the operations of political cauſes in public affairs. Both muſt concur in order to form a completely inſtructive hiſtorian. With regard to the latter, the materials and means of information, poſſeſſed by the ancient hiſtorians, were more circumſcribed and limited than thoſe of the moderns: far leſs communication and intercourſe ſubſiſted between neighbouring ſtates, by the intervention of eſtabliſhed ports, or of ambaſſadors reſident at diſtant courts. Beſides, they wrote for their own countrymen only; they had no idea of writing for the inſtruction of foreigners, whom they deſpiſed, or of the world in general; and hence they are leſs attentive to convey all that knowledge with regard to domeſtic policy, which we, in diſtant times, would deſire to have learned from them. Perhaps alſo, though in ancient ages men were more abundantly animated with the love of liberty, yet the full extent of the influence of government, and of political cauſes, was not then ſo thoroughly ſcrutinized, as it has been in modern times; when a longer experience of all the different modes of government has rendered men more enlightened and intelligent, with reſpect to public affairs. To the reaſons now ſtated it is owing, that though the ancient hiſtorians ſet before us the particular facts which they relate, in a very beautiful and diſtinct manner, yet ſometimes they do not give us a clear view of all the political cauſes which affected the ſituation of affairs, of which they treat. From the Greek hiſtorians, we are able to form but an imperfect notion of the ſtrength, the wealth, and the revenues of the different Grecian ſtates; of the cauſes of ſeveral of thoſe revolutions that happened in their government; or of their ſeparate connections and interfering intereſts. In writing the hiſtory of the Romans, Livy had ſurely the moſt ample field for diſplaying political knowledge, concerning the riſe of their greatneſs, and the advantages or defects of their government. Yet the inſtruction, in theſe important articles, which he affords, is not conſiderable. He is indeed an elegant writer, and a beautiful relater of facts; but by no means diſtinguiſhed for profoundneſs or penetration. Salluſt, when writing the hiſtory of a conſpiracy againſt the government, which ought to have been altogether a political hiſtory, has evidently attended more to the elegance of narration, and the painting of characters, than to the unfolding ſecret cauſes and ſprings. Inſtead of that complete information, which we might naturally have expected from him of the ſtate of parties at Rome, and of that particular conjuncture

conjuncture of affairs, which enabled ſo deſperate a profligate as Cataline to become ſo formidable to the government, he has given us little more than a general declamatory account of the luxury and corruption of manners in that age, compared with the ſimplicity of former times. It is not meant, however, to cenſure all the ancient hiſtorians as defective in political information. No hiſtorians can be more inſtructive than Thucydides, Polybius, and Tacitus.

Thucydides is grave, intelligent, and judicious; always attentive to give very exact information concerning every operation which he relates; and to ſhew the advantages and diſadvantages of every plan that was propoſed, and every meaſure that was purſued. Polybius excels in comprehenſive political views, in penetration into great ſyſtems, and in his profound and diſtinct knowledge of all military affairs. Tacitus is eminent for his knowledge of the human heart; is ſentimental and refined in a high degree; conveys much inſtruction with reſpect to political matters, but more with reſpect to human nature.

The hiſtorian ſhould alſo introduce pertinent and uſeful reflections in the courſe of his narrations. The beſt hiſtorians, ſuch as Salluſt and Livy, &c. have allowed themſelves this liberty. But the remarks or reflections of the hiſtorian ſhould be brief, and differ in this reſpect from the encomiums or declamations of the orator. When obſervations are to be made concerning human nature in general, or the peculiarities of certain characters, if the hiſtorian can artfully incorporate ſuch obſervations with his narrative, they will have a better effect than when they are delivered as formal detached reflections. To this purpoſe we may obſerve, that, in the life of Agricola, Tacitus, ſpeaking of Domitian's treatment of Agricola, makes this reflection: "Proprium humani ingenii eſt, odiſſe quem læſeris;" *i. e.* "It belongs to human nature, to hate the man whom you have injured." This obſervation is juſt and philoſophical; but the form, in which it ſtands, is abſtract and philoſophical. A thought of the ſame kind has a fine effect elſewhere in the ſame hiſtorian, when ſpeaking of the jealouſies which Germanicus knew to be entertained againſt him by Livia and Tiberius: "Anxius," ſays he, "occultis in ſe patrui aviæque odiis, quorum cauſæ acriores quia iniquæ:" *i. e.* "Uneaſy in his mind, on account of the concealed hatred entertained againſt him by his uncle and grandmother, which was the more bitter, becauſe the cauſe of it was unjuſt." This profound moral obſervation is introduced, without the appearance of making it in form, as a part of the narration, in aſſigning a reaſon for the anxiety of Germanicus. Tacitus excels in a talent of intermixing after this manner with the courſe of his narrative many ſtriking ſentiments and uſeful obſervations. For a more particular account of the diſtinguiſhing properties of hiſtorical narration; ſee NARRATION.

Hiſtorians have enlivened their narration, by introducing, on various occaſions, ſpeeches, which are either oblique or direct; the former recited by the hiſtorian in his own perſon. Of this kind is that of Hannibal in Juſtin, by which he endeavours to perſuade king Antiochus to carry the heat of war againſt the Romans into Italy. (Lib. xxxi. cap. 5.) And in the latter, the perſon himſelf is introduced as addreſſing his audience; and therefore the words, as well as the ſenſe, are to be accommodated to his character. Such is the ſpeech of Eumenes, one of Alexander's captains and ſucceſſors, addreſſed to his ſoldiers, when they had traiterouſly bound him in chains, in order to deliver him up to his enemy Antigonus. Juſtin, lib. xiv. cap. 4.

With regard to direct ſpeeches, there are few ancient hiſtorians who have not adopted them, though ſome of our critics will only admit thoſe which were really ſpoken by the perſons to whom they are aſcribed. The firſt hiſtorian who introduced complete and finiſhed ſpeeches into hiſtory, is ſaid to be Thucydides, thoſe of Herodotus being but ſhort and imperfect. (See ORATION.) Letters are ſometimes met with in hiſtories, as well as ſpeeches: ſuch are thoſe of Alexander to Darius in Q. Curtius, lib. iv. cap. 1. and thoſe of Tiberius and Druſus in Tacitus, Ann. lib. i. 73. iii. 53. 59. Digreſſions alſo, when they are neither too long nor too frequent, may be ſo managed by the hiſtorian, as to afford the reader both delight and profit. (See DIGRESSION.) With regard to the order of hiſtory, the hiſtorian ſhould ſo form his introduction, as to give ſome general view of the ſubject, to engage the reader's attention, and to poſſeſs him with a candid opinion of himſelf and of his performance; this ſhould be natural, and proportioned to the extent of the work. Such are thoſe of Livy, Herodotus, Thucydides, Tacitus, and others. But order is to be principally regarded in the body of the work: for this purpoſe the hiſtoriographer ſhould either attend to the time in a chronological ſeries, which is beſt in biography, after the manner of Plutarch and Cornelius Nepos; in the hiſtory of particular ſtates, after Thucydides, Livy, and Tacitus, and ſometimes alſo in a general hiſtory; though in this latter caſe, the order of time cannot always be preſerved, and therefore the actions of each nation, when ſeveral ſtates are independent of each other, muſt neceſſarily be ſeparated, in order to prevent confuſion. This is the method adopted by Herodotus, Diodorus Siculus, and Juſtin.

There is one circumſtance that deſerves to be particularly mentioned, becauſe it deſerves the firſt attention of the intelligent and inſtructive hiſtorian; and this is, that in the conduct and management of his ſubject he ſhould give it as much unity as poſſible; in other words, his hiſtory ſhould not conſiſt of ſeparate unconnected parts merely, but ſhould be bound together by ſome connecting principle, which ſhall make the impreſſion on the mind of ſomething that is one, whole and entire. Whether pleaſure or inſtruction be the end ſought by the ſtudy of hiſtory, either of them is enjoyed to much greater advantage, when the mind has always before it the progreſs of ſome one great plan or ſyſtem of actions; when there is ſome point or centre to which we can refer the various parts related by the hiſtorian. Of all the ancient general hiſtorians, the one who had the moſt exact idea of this quality of hiſtorical compoſition, though, in other reſpects, not an elegant writer, was Polybius. In his third book he ſketches out his own plan; obſerving, that the ſubject of which he had undertaken to write is, throughout the whole of it, one action, one great ſpectacle; how, and by what cauſes, all the parts of the habitable world became ſubject to the Roman empire. "This action," ſays he, "is diſtinct in its beginning, determined in its duration, and clear in its final accompliſhment; therefore, I think it of uſe to give a general view before-hand, of the chief conſtituent parts which make up this whole." In another place, he congratulates himſelf on his good fortune, in having a ſubject for hiſtory, which allowed ſuch variety of parts to be united under one view; remarking, that before this period, the affairs of the world were ſcattered, and without connection; whereas, in the times of which he writes, all the great tranſactions of the world tended and verged to one point, and were capable of being conſidered as parts of one ſyſtem.

Thoſe who write the hiſtory of ſome particular great tranſaction, confining themſelves to one era, or one portion of the hiſtory of a nation, have ſuch great advantages for preſerving hiſtorical unity, that they are inexcuſable if they fail in it. Salluſt's hiſtories of the Catilinarian and

Jugurthine wars, Xenophon's Cyropædia, and his Retreat of the Ten-thouſand, are inſtances of particular hiſtories, where the unity of hiſtorical object is perfectly well maintained. Thucydides, otherwiſe a writer of great ſtrength and dignity, has failed much, in this article, in his hiſtory of the Peloponneſian war. On this account, he is ſeverely cenſured by one of the beſt critics of antiquity, Dionyſius of Halicarnaſſus. This critic is partial to Herodotus, whom, both for the choice and conduct of his ſubject, he prefers to the other hiſtorian. But we may obſerve, that Herodotus wrote to the imagination, and Thucydides writes to the underſtanding. He was a grave, reflecting man, well acquainted with human life; and the melancholy events and cataſtrophes which he records, but which Dionyſius finds fault with, are often both the moſt intereſting parts of his hiſtory, and the moſt improving to the heart. Indeed, the diſtribution of his ſubject, which, though not deficient in dignity, wants the gaiety and ſplendour of that of Herodotus, is faulty, and the critic's obſervations upon it are better founded, and his preference of Herodotus, in this reſpect, is not unjuſt. With regard to ſtyle, Dionyſius gives Thucydides the juſt praiſe of energy and brevity; but cenſures him, on many occaſions, not without reaſon, for harſh and obſcure expreſſion, deficient in ſmoothneſs and eaſe. The hiſtorian, however, muſt not neglect chronological order, with a view to render his narration agreeable. He muſt give a diſtinct account of the dates, and of the coincidence of facts. But he is not under the neceſſity of breaking off always in the middle of tranſactions, in order to inform us of what was happening elſewhere at the ſame time. He diſcovers no art if he cannot form ſome connection among the affairs which he relates, ſo as to introduce them in a proper train. He will ſoon tire the reader, if he goes on recording, in ſtrict chronological order, a multitude of ſeparate tranſactions, without any other connection beſides coincidence of event. Although the hiſtory of Herodotus be of greater compaſs than that of Thucydides, and comprehend a much greater variety of diſſimilar parts, he has been more fortunate in joining them together, and digeſting them into order. Hence he is a more pleaſing writer, and gives a ſtronger impreſſion of his ſubject; though, in judgment and accuracy, much inferior to Thucydides. He abounds, indeed, with digreſſions and epiſodes; but when theſe have any connection with the main ſubject, and are inſerted profeſſedly as epiſodes, the unity of the whole is leſs violated by them, than by a broken and ſcattered narration of the principal ſtory. Among the moderns, the preſident Thuanus has, by attempting to make the hiſtory of his own times too comprehenſive, fallen into the ſame error, of loading the reader with a great variety of unconnected facts, going on together in different parts of the world;—an hiſtorian otherwiſe of great probity, candour, and excellent underſtanding; but through the want of this unity, more tedious, and leſs intereſting than he otherwiſe would have been.

As hiſtory is a ſpecies of writing deſigned for the inſtruction of mankind, ſound morality ſhould always reign in it. Both in deſcribing characters, and in relating tranſactions, the author ſhould always ſhew himſelf to be on the ſide of virtue. To deliver moral inſtruction in a formal manner, falls not within his province; but both as a good man and as a good writer, it is expected, that he ſhould diſcover ſentiments of reſpect for virtue, and of indignation at flagrant vice. Neutrality and indifference, when occaſions of this kind occur, are inexcuſable; and indicate a culpable deficiency in ſenſibility and moral feeling. For the ſtyle of the hiſtorian, ſee STYLE.

So numerous and conſiderable are the qualifications neceſſary for an hiſtorian, that this province was formerly aſſigned by the eaſtern nations to a particular order of men; and both among the Greeks and Romans it was generally undertaken by perſons of figure, and ſuch as were eminent for learning, knowledge of the world, and other great abilities: and as it is of ſuch ſingular ſervice to mankind to have the records of paſt ages well and faithfully tranſmitted to poſterity, it is to be wiſhed that perſons of ſimilar character would, in all countries, undertake it.

Having illuſtrated the qualities of a good hiſtorian by direct or indirect references to ancient writers, it may not be improper to ſpecify ſome inſtances in which the moderns have excelled in this kind of writing. Dr. Blair ſelects Italy as the country in Europe where the hiſtorical genius has, in latter ages, ſhone forth with the greateſt luſtre. Soon after the reſtoration of letters, Machiavel, Guicciardin, Davila, Bentivoglio, father Paul, became highly conſpicuous for hiſtorical merit. All of them appear to have conceived very juſt ideas of hiſtory; and are agreeable, inſtructive, and intereſting writers. They are not, however, without ſome imperfections, which have been pointed out by critics, and detailed by Blair. Among the French, many hiſtorical writers are ſpirited, lively, and agreeable; and ſome of them not deficient in profoundneſs and penetration. Nevertheleſs, France has not produced any ſuch capital hiſtorians as Italy. In our own iſland, Scotland acquired reputation, at an early period, by means of the celebrated Buchanan. He is an elegant writer, claſſical in his Latinity, and agreeable both in narration and deſcription; but ſuſpected to be more attentive to elegance than to accuracy; and inaccurate and imperfect in his political views; and charged with being deeply tinctured with the ſpirit of party. Among the older Engliſh hiſtorians, the moſt conſiderable is lord Clarendon: more impartial in his relation of facts than might have been expected, and diſtinguiſhed by the ſpirit of virtue and probity which pervades his work. He maintains the dignity of an hiſtorian; and though his ſentences are too long and his general manner prolix, his ſtyle is, upon the whole, manly; and his merit, as an hiſtorian, much beyond mediocrity. He is particularly admirable, and perhaps we may ſay unequalled in the drawing of characters. Some have aſſerted that he was the firſt Engliſhman who ſeems to have attempted to write hiſtory with any degree of dignity. But this aſſertion is not ſtrictly accurate. Sir Walter Raleigh and Knowles made the attempt before him, and with no ſmall ſucceſs, and we may aſſert the ſame, in a great degree, concerning ſir Francis Bacon and lord Herbert of Cherbury. However, Clarendon has, in this reſpect, exceeded all his predeceſſors. Biſhop Burnet is lively and perſpicuous; but his ſtyle is too careleſs and familiar for hiſtory; his characters are marked with a bold and a ſtrong hand, but they are generally light and ſatirical; and he abounds too much in little ſtories concerning himſelf, that he reſembles more a writer of memoirs than of hiſtory. For a juſt appreciation of his character as an hiſtorian, ſee the article BURNET. During a long period, Engliſh hiſtorical authors ſeemed to aim at nothing higher than an exact relation of facts; till of late the diſtinguiſhed names of Hume, Robertſon, and Gibbon, have raiſed the Britiſh character in this ſpecies of writing to high reputation and dignity. Dr. Blair obſerves, that of late years a great improvement has begun to be introduced into hiſtorical compoſition; which conſiſts in a more particular attention than was formerly given to laws, cuſtoms, commerce, religion, literature, and every thing elſe that tends to ſhew the ſpirit and genius of nations. An hiſtorian is now expected to exhibit manners, as well as facts and events ; and it muſt be allowed, that whatever diſplays the ſtate and life of mankind in different periods, and illuſtrates the progreſs of the human mind, is more uſeful and intereſting than the detail of ſieges and battles. The introduction of this improvement into hiſtory has been chiefly owing to the celebrated M. Voltaire, whoſe age of Louis XIV. commanded the attention, and claimed the approbation of all Europe. See farther on this ſubject Ward's Oratory, vol. ii. lect. 42, 43, 44, and 45. Blair's Lectures, vol. iii. lect. 36.

The term hiſtoriographer is chiefly uſed for a perſon who has a peculiar charge and commiſſion to write the hiſtory of his time. The hiſtoriographer to his majeſty is an officer under the lord chamberlain ; his ſalary 200*l.* per annum. There is an office of the ſame kind in Scotland with the ſame ſalary.

HISTORY, a recital or deſcription of things as they are, or have been in a continued orderly narration of the principal facts and circumſtances attending them. The word is Greek, ἱςορια, *hiſtoria* ; and literally denotes a ſearch of curious things, or a deſire of knowing, or even a rehearſal of things we have ſeen ; being formed of the verb ἱςορειν, which properly ſignifies to know a thing by having ſeen it ; though the idea appropriated to the term hiſtory is now much more extenſive, and we apply it to a narration of divers memorable things, even though the relator only takes them from the report of others. The origin of the word is from the verb ιςημι, *I know* ; and hence it is, that among the ancients ſeveral of their great men were called *polyhiſtores*, *q. d.* perſons of various and general knowledge.

Hiſtory is divided, with regard to its *ſubject*, into the *hiſtory of nature* and the *hiſtory of actions*.

HISTORY *of Nature*, or *Natural Hiſtory*, is a deſcription of natural bodies ; whether terreſtrial, as animals, vegetables, foſſils, fire, water, air, meteors, &c. or celeſtial, as the ſtars, planets, comets, &c. Natural hiſtory is much the ſame with what we otherwiſe call *phyſiology*. See *Natural* HISTORY and PHYSIOLOGY.

HISTORY, with regard to *actions*, is a continued relation of a ſeries of memorable events in the affairs either of a ſingle perſon, a nation, or ſeveral perſons and nations, and whether included in a great or little ſpace of time ; or, it is a narrative of ſuch facts as are fit to be tranſmitted to poſterity for the uſe of mankind and the better conduct of human life. Cicero calls hiſtory the miſtreſs of life, (De Orat. lib. ii. cap. 9.) as it teaches us both what we ought to purſue and what we ought to avoid.

Thus Thucydides, among the ancients, excellently tranſlated by Smith, and among the moderns, Stanyan, Leland, Gillies, Mitford, the abbe Barthelemi in his Travels of Anacharſis, have written the Hiſtory of Greece ; Livy, among the ancients, and among the moderns, Catrou and Rouille, Rollin, Vertot, Hooke, Ferguſon, Monteſquieu, Crevier, Gibbon, &c. that of Rome ; Mezeray and F. Daniel, of France ; Tyrrel, Echard, Rapin, continued by Tindal, Carte, Guthrie, with the ſupplement of Ralph, Hume continued by Smollett, Henry, &c. Kennett, in his complete hiſtory, including the works of ſeveral writers, of whom the moſt diſtinguiſhed, in point of hiſtorical compoſition and merit, are Milton, Daniel, Bacon, lord Herbert, Camden, and Wilſon, &c. the Hiſtory of England ; Buchanan, not to mention John Major and Hector Boethius, whoſe works are now almoſt obſolete, Robertſon, whoſe hiſtory is a claſſic production, and is thought by many to be the doctor's "Palmarium Opus," G. Stuart, ſir D. Dalrymple, lord Hailes, Guthrie, &c. &c. of Scotland ; O'Connor, Valancy, Ferdinando Warner, O'Halloran, Leland, Crawford, Carte in his Life of the Duke of Ormond ; ſir James Ware in his Lives of the Biſhops and Writers of Ireland, improved and enlarged by Mr. Harris, &c. &c. of Ireland ; Dr. Powel, Warrington, &c. of Wales ; Clarendon, the Hiſtory of the Rebellion ; and Thuanus, biſhop Burnet, &c. the Hiſtory of their own Lives and Times.

Euſebius, Baronius, &c. have written the Hiſtory of the Church ; biſhop Burnet that of the Reformation, &c.

Several authors have written on the Method of reading and ſtudying Hiſtory ; among the reſt Lucian, Bodin, Voſſius the Elder, Whear, Patrici, Beni, Maſcardi, De Silhon, F. le Moine, F. Rapin, the abbot De St. Real, F. Thomaſſin, Freſnoy, Prieſtley, &c.

One of the moſt uſeful directions for facilitating the ſtudy of hiſtory, ſays Dr. Prieſtley in his Lectures, (Lect. 17.) is to begin with authors who preſent a "Compendium," or general view of the whole ſubject of hiſtory, and afterwards to apply to the ſtudy of any particular hiſtory, with which a more thorough acquaintance is deſired. The moſt celebrated epitome of univerſal hiſtory written in Latin, is Turſalin's, which is read in moſt of the foreign univerſities. Boſſuet's Epitome of Univerſal Hiſtory, is greatly and deſervedly admired in France ; but it brings the hiſtory no lower than the time of Charlemagne. One of the moſt uſeful epitomes, upon the whole, is that written by baron Holberg in Latin, and tranſlated with improvements into Engliſh by Dr. Gregory Sharpe. Its principal defect is, that too little notice is taken of the hiſtory of Greece, and that other ſubjects are diſpatched with too much brevity. The moſt valuable of the larger kind of epitomes are Rollin's of the ancient hiſtory, and Puffendorf's of the modern. One of the moſt obvious contrivances to reduce hiſtory into a ſhort compaſs, and to make an entire courſe of it eaſy to be comprehended, and at the ſame time to obſerve a proper diſtinction between the parts of it, has been by "Chronological Tables." See CHRONOLOGY.

Much of the perſpicuity of hiſtory depends on conceiving clearly the order of generations and the right of ſucceſſion in regal and other families. In this reſpect, "Genealogical Tables" are of unſpeakable uſe (See GENEALOGY.) But the moſt ingenious and uſeful contrivance to facilitate the ſtudy of hiſtory, and to aid the imagination in conceiving diſtinctly, and comprehending the whole courſe of it, in all its parts, co-exiſtent and ſucceſſive, is the "Chart of Hiſtory." This is properly a picture of all hiſtory, and is formed by ſuch natural methods of expreſſion, that it renders viſible to the eye, without reading, the whole figure and dimenſions of all hiſtory, general and particular, and ſo perfectly ſhews the origin, progreſs, extent, and duration, of all kingdoms and ſtates that ever exiſted, at one view, with every circumſtance of time and place, uniting chronology and geography, that it not only, in the moſt agreeable manner, refreſhes the memory without the fatigue of reading ; but a novice in hiſtory may learn more from it by a mere attentive inſpection of a few hours, than he can acquire by the reading of many weeks or months. This chart muſt anſwer, in the completeſt manner imaginable, almoſt every uſe of a compendium of hiſtory, proper to be read before a larger and fuller courſe be entered upon ; and it will prevent any confuſion which might ariſe from reading particular hiſtories without a regard to their proper order of time or place, better than any abſtract of univerſal hiſtory whatever. For by caſting our eye for a minute upon this chart, we ſee, at one glance, the contemporary ſtate of the whole world at the period of which we are reading, and the preceding and ſucceeding ſtate of the particular country, the hiſtory of which we are ſtudying. Dr. Prieſtley has conſtructed a chart of this kind, of the ſame ſize with his chart of biography, drawn upon a like ſcale, and made to correſpond to it in all reſpects. Among other methods of illuſtrating and retaining hiſtory, we may mention Mr. Grey's "memorial lines," ſerving to aid us in recollecting dates with exactneſs. To this we may add the uſe of a "common-place book," in which the moſt valuable fruits of hiſtory may be repoſited.

We ſhall here ſubjoin the order in which the principal authors of antiquity ſhould be read, ſo as to obtain from them a regular ſeries of facts, compriſing the hiſtory of Aſia, Africa, Greece, and Rome, till the diſſolution of the empire of Conſtantinople. The oldeſt hiſtory extant, next to the hiſtorical books of the Old Teſtament, is that of "Herodotus," who flouriſhed about 450 years B.C., a little after the invaſion of Greece by Xerxes. His hiſtory compriſes probably every thing which he had an opportunity of learning concerning the hiſtory of the Lydians, Ionians, Lycians, Egyptians, Perſians, Greeks, and Macedonians; and, computing from the earlieſt of his accounts to the lateſt, his hiſtory may be reckoned to commence about 713 years B.C., and to reach to about the year 479 B.C.; a period of about 234 years. A more particular account of ſeveral things in the period of which he treats, may be extracted from the following authors; *viz.* Juſtin (l. i. ii. iii. and vii.), Xenophon's Cyropædia, and the lives of Ariſtides, Themiſtocles, Cimon, Miltiades, and Pauſanias, written by Plutarch and Cornelius Nepos; and thoſe of Anaximander, Zeno, Empedocles, Heraclitus, and Democritus, by Diogenes Laertius. Next to Herodotus, "Thucydides" ſhould be read. Introductory to his hiſtory of the Peloponneſian war, which was his principal and profeſſed ſubject, he gives a ſummary view of the hiſtory of Greece, from the departure of Xerxes to the commencement of that war, which connects his hiſtory with that of Herodotus. To complete the period comprehended by his hiſtory, after his firſt book, the eleventh and twelfth books of Diodorus Siculus ſhould be read, together with Plutarch's Themiſtocles, Ariſtides, Pauſanias, and Cimon, and the ſecond and third books of Juſtin. And, after the whole of Thucydides, the hiſtorical ſtudent ſhould read the lives of Alcibiades, Chabrias, Thraſybulus, and Lyſias, written by Plutarch or Cornelius Nepos, the fourth and fifth books of Juſtin, and the firſt book of Oroſius. After Thucydides, the firſt and ſecond books of "Xenophon's Hiſtory of Greece" ſhould be read. This completes the hiſtory of the Peloponneſian war, with the contemporary affairs of the Medes and Perſians. After this, let the ſtudent proceed to the "expedition of Cyrus," and the return of the Greeks; and laſtly, the remainder of his hiſtory of Greece, which contains an account of the affairs of the Greeks and Perſians to the battle of Mantinæa, which happened in the year 363 B.C.; ſo that all the hiſtorical books of Xenophon compriſe a period of about 48 years. To complete the hiſtory of this period, recourſe may be had to the lives of Lyſander, Ageſilaus, Artaxerxes, Thraſybulus, Chabrias, Conon, and Datames, written by Plutarch or Cornelius Nepos; the fourth and fifth books of Juſtin; and the thirteenth, fourteenth, and fifteenth of Diodorus Siculus. After Xenophon's works let the fifteenth and ſixteenth books of Diodorus Siculus be read; theſe contain the hiſtories of Greece and Perſia, from the battle of Mantinæa to the beginning of the reign of Alexander the Great, in the year 336 B.C. After theſe two books of Diodorus, let Arrian's hiſtory of Alexander be read; and for completing this hiſtory, let the reader recur to Quintus Curtius, the tenth and eleventh books of Juſtin, and Plutarch's life of Alexander. After Arrian, let him peruſe the eighteenth, nineteenth, and twentieth books of Diodorus Siculus, which contain the hiſtory of Greece from the year 323 B.C. to the year 301; and to complete this period, the thirteenth, fourteenth, and fifteenth books of Juſtin, and the Demetrius and Eumenes of Plutarch. After the books of Diodorus, read from the ſixteenth to the twenty-ninth book, incluſive, of Juſtin, which brings down the hiſtory to about the year 195 B.C. After Juſtin, read Plutarch's lives of Pyrrhus, Aratus, Agis, Cleomenes, and Philopœmen. The lives of illuſtrious men written by Plutarch, who flouriſhed about the year 130 after Chriſt, make an excellent ſupplement to univerſal hiſtory. To complete the hiſtory furniſhed by theſe lives of Plutarch, read the fragments of Diodorus. Laſtly, in the regular order of hiſtory, read the thirtieth book of Juſtin, and all that follow till the two laſt, which completes the hiſtory of Greece till it is blended with that of the Romans. All the hiſtories abovementioned are written in Greek, except thoſe of Juſtin, Quintus Curtius, and Cornelius Nepos, which are in Latin.

The following courſe of "Roman Hiſtory" may be conſidered as comprehending all that is now to be learned of the ſubſequent ancient hiſtory of all other nations, beſides Greece and thoſe comprehended in its hiſtory. The writer who treats of the early part of the Roman hiſtory, in the fulleſt and moſt ſatiſfactory manner, is "Dionyſius of Halicarnaſſus," who brought down the hiſtory of Rome as far as the beginning of the firſt Punic war. But of his work, which conſiſted of twenty books, the eleven firſt are all that are extant, and they end at the year 341 B.C., the time when the conſuls reſumed the chief authority in the republic, after the diſſolution of the decemvirate. To complete the hiſtory of the period of which he treats, read Livy (l. i. ii. and iii.), Plutarch's Romulus, Numa Pompilius, Valerius Poplicola, Coriolanus, and Camillus. After Dionyſius, read from the fourth to the tenth book incluſive of Livy, which brings the hiſtory of Rome to the year 292 B.C. To ſupply the chaſm between the tenth and twentieth books of Livy, read Polybius, particularly the firſt and ſecond books, which treat chiefly of the firſt Punic war; the epitome of the ſecond decad of Livy, books ſeventeen, eighteen, twenty-two, and twenty-three of Juſtin, fourteen chapters of the fourth book of Oroſius, the fourth and fifth of the third book of the "hiſtoria miſcellanea" of Paulus Diaconus, Plutarch's Marcellus, and Fabius Maximus; the ſecond tome of the Annals of Zonaras, and Appian's Punic and Illyrian wars. After Appian ſhould be read the remainder of Livy, from the twenty-firſt book to the end, which brings the hiſtory to the year 166 B.C., and the epitome to the end. To complete the laſt books of Livy, read Plutarch's Hannibal, Scipio Africanus, Quintus Flamininus, Paulus Æmilius, and Cato Major. After this read his Gracchi, Marius, Sylla, Cato Minor, Sartorius, Lucullus, Pompey, and Brutus. The reader of hiſtory muſt next proceed to Salluſt's hiſtory of the war of Jugurtha, which happened 100 years B.C., and of the conſpiracy of Catiline, which happened 62 years B.C. Next ſhould follow Julius Cæſar's Commentaries of his own wars, and the ſupplement by Hirtius and others. To obtain a clear idea of this important period of time, Cicero's epiſtles, eſpecially thoſe to Atticus, ſhould not be overlooked. The hiſtory of Dio Caſſius compriſed all the time from the building of Rome to the reign of Alexander; but to ſupply the want of the laſt twenty, we muſt be content with what Xiphilinus, who wrote A.D. 1050, has given us in a compendium of them. The period of which Dio Caſſius treats will be made more complete by Velleius Paterculus, who lived under Tiberius. We ſhould then have recourſe to Suetonius's lives of the twelve Cæſars; and next to Tacitus's annals and hiſtory. This hiſtory contains a fund of political knowledge, and, on that account, is very proper to be ſtudied by princes and miniſters of ſtate. Tacitus is the laſt Roman hiſtorian who is worth reading, except barely for thoſe *facts* which we have no other method of becoming acquainted with. Suetonius and Tacitus are generally placed in what is called the "ſilver age" of the Latin tongue; but all the ſucceeding writers are univerſally thrown into the "brazen," or "iron" age. Theſe, in the order according to which they ſhould be read, are, the lives of Nerva and Trajan by Aurelius Victor or Xiphilin, Spartian's Adrian, Capitolinus's Antoninus, Herodian, the Scriptores Romani, or Hiſtoriæ Auguſtæ Scriptores, *viz.* Spartianus, Lampridius, Capitolinus, Vulcatius, Trebellius Pollio, and Vopiſcus ſupplying the chaſm in theſe writers between Gordian III and Valentinian, from Aurelius Victor, and then the hiſtory will be brought down to A.D. 283. Eutropius will furniſh a good epitome of the Roman hiſtory till about this time, in Latin. All the writers of the Roman hiſtory from this time are Greek, except Ammianus Marcellinus; they are Zozimus, A.D. 507; Zonaras, A.D. 1119; Jornandes, A.D. 540; Ammianus Marcellinus, A.D. 375; Procopius, A.D. 502; Agathias, A.D. 567; Nicetas Acominatus, A.D. 1203; Nicephorus Gregoras, A.D. 1341; and Johannes Cantacuzenus, A.D. 1350. In this enumeration we ought not to have omitted a celebrated female hiſtorian, *viz.* Anna Comnena, the daughter of Alexius I., emperor of Conſtantinople, who wrote the hiſtory of the reign of her own father, in which ſhe makes the firſt mention of the arrival of the cruſaders at Conſtantinople, and gives an account of their conduct during their reſidence in that city, and their paſſage into Aſia. Her narration is not very favourable to the cruſaders. The concluſion of the hiſtory of Conſtantinople, with the riſe and progreſs of the Turks, may be learned from Laonicus Chalcondiles, who put an end to it. He begins his hiſtory with Ottoman, the ſon of Orthogul, who began to reign about the year of Chriſt 1300. His work conſiſts of ten books, and brings the hiſtory to the year 1453, in which Conſtantinople was taken by Mahomet II.

Of all the modern compilations, derived from theſe ſources of hiſtorical knowledge, none are ſo uſeful as thoſe which treat of the manners, cuſtoms, and laws of the Greeks and Romans. The moſt complete body of Greek and Roman antiquities is that of Grævius and Gronovius; but this is voluminous and expenſive. A perſon may acquire knowledge enough of this kind, for the purpoſe of reading the Greek and Latin hiſtorians, in Potter's excellent and compendious ſyſtem of Greek antiquities, and in Kennett's Antiquities of Rome. Books which contain collections of coins and inſcriptions ſhould not be neglected; the principal collectors of theſe kinds of records are Gruter, Lipſius, Chiſhul, Montfaucon, Prideaux, Mazochius, and Fleetwood for inſcriptions; and Spanheim, Urſinus, Patin, Vaillant, Hardouin, and Goltzius for coins. In ſtudying the Roman hiſtory, a perſon ſhould become converſant with the civil law, which contains the hiſtory of the domeſtic policy of that great people. He ſhould therefore acquaint himſelf at leaſt with "Juſtinian's Inſtitutes;" which contain an authentic outline of their policy. The modern compilations of ancient hiſtory are very numerous; but the moſt complete are "Rollin's" and the "Univerſal Hiſtory." Rollin's ancient hiſtory has been often recommended to young perſons, and it well deſerves their attention. Though the author is only a compiler, he is eloquent. He always writes on the ſide of virtue, and his moral reflections are uſeful; though he cannot be conſidered as diſtinguiſhed by an extraordinary degree of critical ſagacity. The "Ancient Univerſal Hiſtory" is a work of eſtabliſhed reputation and utility. Its references to original authors are numerous; and though it is, with reſpect to judgment and ſtyle, very unequal, and its chronology is various, as it was executed by different perſons, yet it indicates unqueſtionable traces of labour in reſearch, and impartiality in detail. Its faults, compared with its excellencies, are trifling. The oriental part is particularly entitled to applauſe, as it conveys a variety of knowledge, which could not otherwiſe have been eaſily obtained. One principal advantage is, that it gives a ſeparate hiſtory of every individual nation, however inconſiderable; ſo that we ſee at once its relative importance, and its connection with the greater empires, by which it might, at length, be ſwallowed up. The beſt editions of the ancient univerſal hiſtory are, that in folio, and the firſt which appeared in 8vo.

As for thoſe who wiſh to ſtudy the Engliſh hiſtory by the peruſal of the works of original writers, and who have leiſure for this purpoſe, we would refer them for an account of them to Nicholſon's Engliſh Hiſtorical Library. Hence, and from other ſources of information, they will be led to acquaint themſelves with Gildas, the moſt ancient Britiſh hiſtorian, who was born in the year 520, and publiſhed his treatiſe "De excidio Britanniæ" towards the cloſe of his life; the venerable Bede, who was born in 672 or 673; Nennius in 830; Hoel Dha's laws, enacted about the middle of the tenth century; Geoffrey of Monmouth, about the year 1150, the greater part of whoſe work is fabulous; Caradoc, monk of Lancarvan, contemporary with Geoffrey, who wrote a hiſtory of the petty kings of Wales, tranſlated from the Latin original into Engliſh, by Humphrey Llwyd, and enlarged by Dr. Powel, and again by W. Wyn, &c. The oldeſt hiſtory of the Saxon affairs is the "Saxon Chronicle," firſt publiſhed by Abraham Wheelock, the work of unknown authors, and terminating at various periods from 977 to 1154. The earlieſt account we have of the reign of Alfred is that of Aſſerius, his contemporary: the next Saxon hiſtorian is Ethelward, or Edward Patritius in 1090, who continued his chronicle of the Saxon kings no farther than Edgar. Many things relating to the civil government of theſe times are diſperſed in ſome particular lives of their ſaints and kings; particularly thoſe of Offa, Oſwin, Ethelwolf, and Edward the Confeſſor. Of the later writers of the Saxon affairs we may mention Verſtegan in his "Reſtitution of decayed intelligence in Antiquities," corrected by Sheringham and Somner; Selden in his "Analecta;" and Sheringham in his treatiſe "De Anglorum gentis origine." The "Sachſen Spiegel," or "Speculum Saxonicum," is an excellent manual of the old laws of the ancient Saxons. The hiſtory of Great Britain, in certain periods of it, is much connected with the hiſtories of Norway and Denmark; and therefore the Daniſh antiquities ſhould be inveſtigated, and the Runic characters underſtood. The Daniſh antiquary ſhould alſo be acquainted with the beſt Iſlandic hiſtorians, the moſt ancient of whom is Aras Frode, contemporary with Sæmond, about the year 1124; part of whoſe hiſtory of Iceland was publiſhed in 1689 by the biſhop of Skalholt. There are two Norwegian hiſtories which ſhould be conſulted; the former written ſoon after the year 1130 by Theodoric, a monk, and the other compiled by Snorro Sturleſonius, both of whom draw their materials from the ballads of the Scaldri, whoſe hiſtorical poems, it is generally thought, may be depended upon.

Two Daniſh hiſtorians, of principal importance to the Engliſh antiquary, in the judgment of Mr. Nicholſon, are Saxo Grammaticus, and his contemporary Sweno Agonis, of both which we have an excellent edition by Stephanus. The former died at Roſchild in 1204; and by his own account, he compiled his hiſtory out of the Icelandic ballads; and Sweno declares that he compiled his from the traditions of old people. The great reſtorer of the decayed antiquities of Denmark was Olaus Wormius, in his "Literatura Runica," and "Monumenta Danica," to whoſe diſcoveries an addition has been made by Thomas Bartholine. Much light has lately been thrown on this ſubject by various antiquaries, and particularly by Mr. Jonſtone, profeſſor Thorkelin, and Mr. Pinkerton. The firſt of our Engliſh hiſtorians after the conqueſt was Ingulphus of Croyland, who begins A.D. 626, and ends A.D. 1089. About the ſame time Marianus Scotus brought down our Engliſh hiſtory as low as the year 1083. The earlieſt hiſtory in the 12th century was written by Florentius Bravonius, a monk of Worceſter, whoſe book ended with his life in 1119; but it was continued 50 years farther by another monk of the ſame monaſtery. Our next hiſtorian was Eadmerus, a monk of Canterbury, whoſe "Hiſtoria Novorum, &c." was publiſhed by Mr. Selden, and extends from 1066 to 1122. William of Malmſbury is one of the moſt important and valuable of our ancient hiſtorians. He is highly commended by Leland and others. He wrote "De geſtis regum Anglorum" in five books, with an appendix in two more, which he ſtyles "Novellæ hiſtoriæ." His hiſtory comprehends the affairs of England from the firſt arrival of the Saxons to the cloſe of the reign of king Stephen. Simeon Dunelmenſis, monk of Durham in 1164, author of "De Geſtis Regum," commences with the death of Bede in 732 and ends in 1129. Ealred, abbot of Rievaulx, gives a ſhort genealogy of our kings to Henry II., but chiefly enlarges in praiſe of David king of Scots, founder of many Ciſtercian abbies. About the ſame time flouriſhed Henry, archdeacon of Huntington, whoſe eight books, concluding with the reign of king Stephen, were publiſhed by ſir Henry Savile. William of Newberry begins at the death of Henry I., and ends in the year 1097. The 13th century begins with Gervaſe monk of Canterbury, who is ſaid to have been a judicious antiquary and methodical hiſtorian, and to have made an excellent collection of the Britiſh and Engliſh hiſtory from the arrival of the Trojans to the year 1200. All that is extant commences with the year 1112, the 12th year of Henry I., and ends with the death of Richard I. It bears the character of being executed with great judgment. Cotemporary with theſe two, was Roger de Hoveden, chaplain to king Henry II., who has deduced our hiſtory to the year 1202, the 4th year of king John's reign. The next hiſtorian of note is Ralph de Diceto, dean of London, who, about the year 1210, compoſed two treatiſes, entitled "Abbreviationes Chronicorum," compriſing an abſtract of our hiſtory, chiefly eccleſiaſtical, down to the conqueſt, and "Imagines hiſtoriarum," containing the hiſtory of ſome of our kings, terminating with the firſt year of king John's reign. Selden much admires this author and his works. Theſe writers were ſoon ſucceeded by Matthew Paris, a monk of St. Alban's, who is reckoned the firſt in value and reputation of all our ancient hiſtorians. His hiſtory comprehends a very important period, from the beginning of the reign of William I. to the end of that of Henry III., and the information it contains is equally curious and uſeful. His mode of writing is, on the whole, pleaſing and agreeable, and his compoſition ſimple and perſpicuous. The ſpirit with which he expoſes the pretenſions and conduct of the Roman pontiffs is admirable; and it is no wonder that, on this account, he ſhould be diſparaged by Bellarmine and Baronius. His hiſtory was firſt publiſhed at London in 1571, and at Zurich in 1589. It again appeared in 1606; but the beſt edition is that of Dr. W. Watts in 1640. Watts's edition again appeared in 1684, but this edition is not equal to the firſt impreſſion. The 14th century begins with Thomas Wikes, whoſe hiſtory begins at the conqueſt, and ends at the death of Henry I., A.D. 1304. Nicholas Trivet, who was buried in the year 1328, and his contemporary, Roger Ceſtrenſis, deſerve curſory mention. The chronicle of John Brompton begins with the coming in of Auguſtin the monk in 528, and ends with the death of Richard I. A.D. 1198: this author has given a collection and verſion of the Saxon laws in Latin, made in the time of Edward III. The chronicle of Walter Hemmingford, who flouriſhed in the reign of Edward III. begins in 1066 and ends with the year 1308. Ralph Higden wrote a hiſtory, ſtyled "Polychronicon," chiefly compiled from the writings of other, and old chronicles now loſt. He died in the year 1377. John, vicar of Tinmouth, was a great collector of Engliſh hiſtories, which he digeſted in three very large volumes; they chiefly relate to the miracles of Engliſh ſaints. He was a monk of St. Alban's in 1366. Matthew, a Benedictine monk of Weſtminſter, was a great collector of former hiſtorians, and therefore uſually ſtyled "florilegus." His hiſtory ends at the year 1307, which he probably did not long ſurvive. It was continued by others; chiefly by Adam Merimuth, canon regular of St. Paul's, who begins in 1302, and ends in 1380, probably the year of his death. Henry Knighton wrote a chronicle "Of the Events of England," from the time of Edgar, in 958, to the year 1395, the 19th year of Richard II. in whoſe time he lived. Although he does not rank high as an hiſtorian, he is valuable for the account he gives of the proceedings againſt Richard II. from which it appears how free our conſtitution was underſtood to be at that period, and how great were the prerogative and power of parliament. His "Chronicon, de Eventibus Angliæ," and his "Hiſtoria depoſitionis Ricardi ſecundi," are both preſerved in Twiſden's "Decem Scriptores." The 15th century was one of the moſt rude and illiterate ages. Amongſt the few eminent for learning was ſir John Froiſſart, whoſe work contains a general hiſtory of the affairs of France, Spain, and other parts of Europe; but he alſo particularly inſiſts on the wars between the Engliſh and French, from 1335 to 1400. (See his biographical article.) The next hiſtorian worthy of notice is Thomas Walſingham, a monk of St. Alban's, and probably regius profeſſor of hiſtory in that monaſtery, about the year 1440. His ſhort hiſtory begins at the concluſion of Henry the Third's reign, where Matthew Paris ends, and is continued to the end of Henry V. His "Hypodigma Neuſtriæ," regards the affairs of Normandy from the time of Rollo to the ſixth year of Henry V. in which are many occurrences not elſewhere to be found. William Caxton continued a hiſtory begun by the monks of St. Alban's, which commenced with the firſt inhabitants of this iſland, to the laſt year of Edward IV. 1483. The whole work bears the title of "Fructus Temporum." John Roſs travelled over England, and made collections out of the libraries to which he had acceſs, pertaining to the hiſtory and antiquities of this kingdom. They are preſerved in the Britiſh muſeum; and contain many particulars that illuſtrate the antiquities of our univerſities. Of the hiſtorians above recited, thoſe whoſe works are entitled to diligent peruſal by the hiſtorical ſtudent, are Ingulphus, Eadmerus, William of Malmſbury, Roger de Hoveden, William of Newberry, Matthew of Paris, Matthew of Weſtminſter, Henry Knighton, and Froiſſart. Moſt of our ancient hiſtorians will be found in ſir Henry Savile's "Quinque Scriptores Anglicæ Hiſtoriæ," 1596; in the "Decem Scriptores" of 1629; in the "Decem Scriptores" by Twiſden, in 1652; in the "Rerum Anglicanarum Scriptores," publiſhed at Oxford in 1684; and in the two volumes of Dr. Gale, the firſt containing five, and the ſecond 15 hiſtorical writers. There are ſeparate editions of Merianus and Duodechinus, of Florentius, of Eadmerus, of Matthew Paris, of Trivet, of Matthew of Weſtminſter, of Froiſſart, of T. Walſingham, and of W. Caxton. Of the hiſtorians in the 16th century, we may mention Robert Fabian, who died in 1512, whoſe "Hiſtoriarum Concordantiæ," bring down the hiſtory from Brutus to William the Conqueror, in the firſt ſix books; and in the ſeventh he gives the hiſtory of our kings from the Conqueror to Henry VII.; Polydore Virgil, an accompliſhed writer, who wrote the hiſtory of our nation in Latin to Henry VIII.; Edward Hall, who died in London in 1547, and who wrote a diffuſe account of the wars between the houſes of York and Lancaſter, dedicated to Henry VIII.; Harriſon and Hollingſhead, whoſe chronicle is greatly eſteemed; the ſecond edition of this hiſtory was continued to the year 1586 by John Hooper, alias Vowel. In the 17th century the firſt author who occurs is John Stow, who was an induſtrious ſtudent, and a critical collector; he died in 1605; John Speed wrote a chronicle, which is the largeſt and the beſt, ſays Nicholſon, that is extant; it begins with the firſt inhabitants of this iſland, and ends with the union of the two kingdoms under king James, to whom it is dedicated; Richard Baker, who died in the Fleet, in 1644, publiſhed a chronicle, which was well received; the author himſelf wrote the hiſtory of our kings from the Romans to the end of the reign of James I. and it was continued to the reſtoration by Edward Philip. In later times we have had a great number of hiſtorians, or compilers of hiſtory. Among theſe we may enumerate ſir Winſton Churchill, Sandford, Brady, a zealous advocate for the royal prerogative, Tyrrel, a ſtrenuous defender of the ancient rights and privileges of the people, Echard, now almoſt forgotten; Carte, a non-juror and a Jacobite, whoſe general hiſtory, notwithſtanding his peculiar opinions and attachments, is undoubtedly a production of great merit in point of information; Guthrie, much neglected, but undeſervedly, as he is a faithful and diligent writer, who had recourſe to original evidence, though in the latter part of his work he inclines too much to Tory principles; and Ralph, whoſe critical hiſtory of the reigns of Charles II. and James II. is a ſupplement to Guthrie, and is a curious and valuable performance. The more conſiderable hiſtorians, whom we ſhall mention, are Clarendon, of whoſe hiſtory we have already given an account; Whitelocke, whoſe Memorials contain a rich repoſitory of moſt valuable materials; Ludlow, an honeſt and zealous republican; Burnet (ſee his article, and above); Rapin, who ſpent 20 years in the compoſition of his excellent hiſtory, and who, though tedious, is on the whole faithful and impartial; Tindal, the continuator of Rapin, Hume, Smollet, Henry, Lyttelton, Harris, Macaulay, &c. &c. &c.; and a great number of others, who have written hiſtories of particular lives and reigns, and whoſe names we cannot recite.

Hiſtory, with reſpect to *time*, is divided into *ancient* and *modern*, diſtinguiſhed into ſeveral epochs, periods, and intervals.

The three periods of time into which hiſtory has been divided are the following, *viz.* the *firſt*, from the creation to the deluge, which age is reckoned uncertain, becauſe we know no more than the ſhort account given of it in the holy ſcriptures; the *ſecond*, from the deluge to the firſt Olympiad, which, from the many feigned ſtories related in it, is called the fabulous age; the *third*, from the firſt Olympiad to our own times, is called hiſtorical, becauſe the actions done in that period are recorded by writers of true hiſtory. See Age and Chronology.

The moſt ancient of the Greek hiſtorians now left is Herodotus, who lived, according to ſir Iſaac Newton's Chronology, 157 years after the building of Rome. And as to the Romans, Livy himſelf confeſſes, that there were ſcarcely any certain memoirs of their affairs till the city was taken by the Gauls, which was above 100 years later than Herodotus; the accounts before this time having been preſerved chiefly by tradition.

Hiſtory, with reſpect to its *ſubject*, is divided into *univerſal* and *particular*, *ſacred* and *profane*.

F. Meneſtrier gives us the proper characters of the divers kinds of hiſtory with great accuracy. He diſtinguiſhes hiſtory with regard to both its matter and its form, and gives curious inſtances of each particular.

Hiſtory, with regard to its *matter*, is either *ſacred*, or *natural*, or *civil*, or *perſonal*, or *ſingular*; to which ſome have added *artificial hiſtory*, giving an account of the origin and progreſs of arts; and *miſcellaneous hiſtory*, which recites many various things as they promiſcuouſly occur in human life.

History, *ſacred*, is that which lays before us the myſteries and ceremonies of religion, viſions, or appearances of the Deity, &c. miracles, and other ſupernatural things, of which God alone is the author. Such are, the book of Geneſis, the Goſpels, Apocalypſe, &c. See Miracles, Prophecy, Revelation, &c.

To this we may refer *eccleſiaſtical hiſtory*, which gives an account of the riſe and eſtabliſhment of the ſeveral religions and churches, of the riſe and progreſs of various opinions, ſects, &c. In ancient *ſacred* hiſtory, otherwiſe called the hiſtory of the Old Teſtament, there are ſeven remarkable periods. The firſt comprehends 1656 years, from the creation of the world to the deluge; (ſee *Sacred* Chronology.) The ſecond period includes 857 years, from the deluge to the going forth of the Iſraelites out of Egypt. (See Deluge.) The third period begins with the exodus of the Iſraelites in 2513, extends to the times of the kings, and includes 396 years. (See Exodus.) The fourth period begins in the year of the world 2909, or from the beginning of the government by kings, and extends to the end of the Babyloniſh captivity, or 3468th year of the world, including 559 years. (See Captivity.) The fifth period amounts to 372 years, from the year of the world 3468 to the year 3840, or to the times of the Maccabees. (See Maccabees.) The ſixth period begins with Judas Maccabæus, A.M. 3840, and is continued to the year 3964, or to Herod the Great, comprehending 124 years. (See Herod *the Great.*) The ſeventh, or laſt period reaches from Herod the Great to the deſtruction of Jeruſalem, or the 70th year after the birth of Chriſt, containing 106 years. See Jeruſalem.

In more *modern ſacred* hiſtory, more properly called *eccleſiaſtical* hiſtory, which denotes a clear and faithful narration of the tranſactions, revolutions, and events, that relate to the external and internal ſtate of the Chriſtian church, Dr. Moſheim has diſtinguiſhed four remarkable periods. The firſt comprehends the ſtate and viciſſitudes of the Chriſtian church, from its commencement to the time of Conſtantine the Great. The ſecond period extends from the reign of Conſtantine to that of Charlemagne, which produced ſuch a remarkable change in the face of Europe. The third period contains the hiſtory of the church from the time of Charlemagne to the memorable period when Luther roſe in Germany to oppoſe the tyranny of Rome, and to deliver divine truth from the darkneſs that covered it. The fourth period reaches from the time of Luther to the preſent times. On this plan Dr. Moſheim's eccleſiaſtical hiſtory, a work deſervedly held in great eſteem, is divided into four books, containing the hiſtory of the centuries comprehended by the above periods according to the order of time. (See Holberg's Introduction to Univerſal Hiſtory, tranſlated by Dr. Sharpe, with notes, &c., p. 55, &c. ed. 1758; and Moſheim's Eccleſiaſtical Hiſtory, tranſlated by Dr. Maclaine, with notes, &c. compriſed in 6 vols. 8vo. vol. i. p. 12.) To this work Dr. Warburton, the late learned biſhop of Glouceſter, bears the following teſtimony: "Moſheim's Compendium is excellent, the method admirable indeed, the only one deſerving the name of an eccleſiaſtical hiſtory." He adds, "It deſerves frequent notes."

History, *natural*, is a deſcription of the ſingularities of nature, its irregularities and prodigies, and the alterations it undergoes in the birth, progreſs, end, and uſe of things. Such is Ariſtotle's Hiſtory of Animals, Theophraſtus's Hiſtory of Plants, and the entire body of Natural Hiſtory by Pliny; ſuch alſo are Acoſta's Natural Hiſtory of the Indies, Plott's Hiſtory of Staffordſhire, &c.

History, *civil*, is that of people, ſtates, republics, communities, cities, &c. Such are thoſe of Thucydides, Halicarnaſſus, Livy, Polybius, Mezeray, F. Daniel, Milton, Buchanan, &c.

Civil hiſtory may again be ſubdivided into *particular* and *general*: the former conſiſts of a number of facts relating to the ſame ſtate, ſuitably connected and laid together in a proper ſeries; ſuch are Thucydides's Hiſtory of the Peloponneſian War, compriſing the events of the firſt twenty years of that war; Salluſt's Hiſtory of the War between the Romans and king Jugurtha in Africa; and Cæſar's Hiſtory of his own Gallic and civil Wars: the latter, or *general* hiſtory, is made up of ſeveral particular *hiſtories*, whoſe ſeparate tranſactions within the ſame period of time, or part of it, ſhould be ſo diſtinctly related as to cauſe no confuſion; ſuch are thoſe of Diodorus Siculus, of Herodotus, of Juſtin, of Xenophon, and of Polybius, among the ancients; and Thuanus's Hiſtory; Lord Littelton's Hiſtory of Henry II; Dr. Robertſon's Hiſtory of Charles V. &c. among the moderns.

Civil hiſtory, in its more unlimited extent, is denominated *univerſal* hiſtory. See History with regard to *actions*, ſupra.

History, *perſonal*, is that which gives the portrait or life of ſome ſingle perſon. Such are the lives of Plutarch, Cornelius Nepos, Suetonius, &c. and the lives of the painters, philoſophers, ſaints, &c.

Perſonal hiſtory is the ſame with what we otherwiſe call *biography*, and may be denominated *literary* hiſtory, as it records the lives and productions of learned men, the controverſies that ſubſiſted amongſt them, and the riſe and advancement of ſciences. See Biography.

History, *ſingular*, is that which deſcribes a ſingle action, ſiege, battle, or even a war or expedition, &c. Such was the conſpiracy of Catiline to ſubvert the Roman ſtate written by Salluſt.

Hiſtory, with regard to its *form*, is either *ſimple*, or *figurative*, or *mixed*.

History, *ſimple*, is that delivered without any art or foreign ornament; being only a naked and faithful recital of things, juſt in the manner and order wherein they paſſed. Such are the Chronicles of the Eaſtern Empire, the Faſti, Chronological Tables, Journals, &c.

History, *figurative*, is that which is farther enriched with ornaments, by the wit, ingenuity, and addreſs of the hiſtorian. Such are the political and moral hiſtories of the Greeks, Romans, and moſt of the moderns.

This latter is a kind of rational hiſtory, which, without ſtopping at the ſhell or outſide, the appearances of things, diſcovers the ſecret ſprings and movements of the ſeveral events; it enters into the thoughts, the breaſts of the perſons concerned therein; diſcovers their intentions and views; and, by the reſult of enterprizes and undertakings, diſcovers the prudence or weakneſs wherewith they were laid, conducted, &c. Theſe are much the moſt uſeful and entertaining hiſtories. To this claſs may be particularly referred the Hiſtories and Annals of Tacitus, among the ancients; and thoſe of Guicciardin, Thuanus, and biſhop Burnet, among the moderns.

History, *mixed*, is that which, beſides the ornaments of figured hiſtory, calls in the proofs and authorities of ſimple hiſtory, furniſhing authentic memoirs, or original letters, manifeſtoes, declarations, &c. to vouch the truth of what is ſaid. Such are Hiſtories or Collections of Ruſhworth, M. Rapin Thoyras's Hiſtory of England, the Genealogical Hiſtories of Ducheſne, M. De Marca's Hiſtory of Berne, &c.

We ſhall cloſe this article of Hiſtory in general, with a brief recapitulation and illuſtration of the benefits that are likely to reſult from the diligent ſtudy of it; and here we ſhall avail ourſelves of the excellent remarks of Dr. Prieſtley in his "Lectures on Hiſtory." The firſt and loweſt uſe of hiſtory is, that it agreeably amuſes the imagination, and intereſts the paſſions, and, in this view of it, it far ſurpaſſes all works of fiction. The latter reſembles thoſe machines that are contrived to illuſtrate the principles of philoſophy, ſuch as globes and orreries, the uſes of which extend no farther than the views of human ingenuity: whereas real hiſtory reſembles the experiments made by the air-pump, the condenſing engine, or electrical machine, which exhibit the operations of nature, and the God of nature himſelf, whoſe works are the nobleſt ſubject of contemplation to the human mind, and are the ground-works and materials of the moſt extenſive and uſeful theories. Fiction requires a variety of embelliſhments to excite and intereſt the paſſions; whilſt the mere thought that we are liſtening to the voice of truth ſerves to keep the attention awake through many dry and ill-digeſted narrations of facts. The next, and higher uſe of hiſtory, is to improve the underſtanding, and ſtrengthen the judgment, and thus to fit us for entering upon life with advantage. Hiſtory preſents us with the ſame objects which occur to us in the buſineſs of life, and affords ſimilar exerciſe to our thoughts; ſo that it may be called anticipated experience. In ſome reſpects it will be a better guide to us in the conduct of life than experience: becauſe the examples which it preſents to us are generally complete, and we ſee them through a leſs partial medium than that of experience. Hiſtory is, therefore, of great importance not only to the advancement of political knowledge, but to that of knowledge in general, becauſe the moſt exalted underſtanding is merely a power of drawing concluſions, and forming maxims of conduct from known facts and experiments, of which neceſſary materials of knowledge the mind itſelf is wholly barren, and with which it muſt be furniſhed by experience. By improving the underſtanding hiſtory frees the mind from many fooliſh prejudices that tend to miſlead it. Such are thoſe prejudices of a national kind, that have induced an unreaſonable partiality for our own country, merely as our own country, and as unreaſonable to foreign nations and foreign religion, which nothing but the enlarged views reſulting from hiſtory can cure. It likewiſe tends to remove thoſe prejudices that may have been entertained in favour of ancient or modern times, by giving a juſt view of the advantages and diſadvantages of mankind in all ages. To an inhabitant of Great Britain it will be one of the greateſt advantages reſulting from the ſtudy of hiſtory, that, ſo far from producing an indifference to his own country, it will diſpoſe him to be ſatisfied with his own ſituation, and render him, from rational conviction, and not from blind prejudice, a more zealous friend to the intereſts of his country. It is from hiſtory that all future improvements in the ſcience of government muſt be derived, and this ſcience, it will be allowed, is of primary importance and intereſt to thoſe who have ſufficient abilities for the ſtudy of it, and who are friends of mankind. Another very capital advantage of hiſtory is, that it tends to ſtrengthen the ſentiments of virtue. It conduces to this purpoſe by diſplaying the ſentiments and conduct of truly great men, and thoſe of a contrary character, and thus inſpiring us with a taſte for ſolid glory and real greatneſs; whilſt it convinces us that theſe qualities do not conſiſt in the attainments which mankind are too generally purſuing. That true greatneſs does not conſiſt in *riches* may by evinced by the examples of Cincinnatus, Fabricius, Scipio Æmilianus, and other Romans in the early ages of their city, who were honoured for their poverty. The emperors Nerva, Trajan, Antoninus, and Aurelius, ſold their palaces, their gold and ſilver plate, their valuable furniture, and other ſuperfluities heaped up by their predeceſſors, and baniſhed from their tables all expenſive delicacies. Theſe princes, together with Veſpaſian, Pertinax, Alexander Severus, Claudius the ſecond, and Tacitus, who were raiſed to the empire by their merit, and whom all ages have admired as the greateſt and the beſt of princes, were always fond of the greateſt plainneſs in their apparel, furniture, and outward appearance. When the famous Cornelia, daughter of the great Scipio, was importuned by a lady of her acquaintance to ſhew her toilette, ſhe deferred ſatisfying her curioſity till her children, who were the famous Gracchi, came from ſchool, and then ſaid "En! hæc ornamenta mea ſunt." "Theſe are my ornaments." Can we think that *honours* and *preferments* conſtitute true greatneſs, when hiſtory teaches us that the moſt worthy men have generally declined them? On the other hand, the extravagances of Alexander the Great in killing his beſt friends, the cruelties of the Spaniards in America, the ruin of Sweden by Charles XII. are certainly more proper to ſhew the folly and madneſs of unbounded ambition, than their victories are to dazzle our minds with their glare. Nothing ſo effectually cures a man of the abſurd pride of *birth* and *family*, as ſeeing ſome of the greateſt men in hiſtory, ſuch as Tamerlane, cardinal Ximenes, and pope Sixtus V. riſe from low beginnings. Even Veſpaſian laughed at thoſe who pretended to derive his deſcent from Hercules. An exceſſive paſſion for *fame*, as an end of action, reduces a man very low in the light of hiſtory. On the contrary, how prodigiouſly does the character of Cato riſe upon us by a few words of Salluſt: "Maluit eſſe, quam videri, bonus;" "He rather choſe to *be*, than to *ſeem*, good." The vanity of Nero upon his excelling in muſic, and gymnaſtic exerciſes, and of Commodus on his dexterity in killing wild beaſts, completely expoſes the affectation of gaining eminence in what is out of our proper ſphere. The ſame maxim is conveyed by Philip, when he aſked his ſon Alexander, if he was not aſhamed to play on a muſical inſtrument ſo well as he did. A ſimple narration of ſome hiſtorical incidents excites an admiration of true greatneſs of mind more than the moſt elaborate deſcription of it. What can give us a clearer idea of the noble ſentiments of ſtrict honour and integrity, than Marſhal Turenne's refuſing a ſum of money, which was offered him, if he would not march his army through a certain territory, becauſe he had not intended to march that way! Does not every perſon's heart ſtrongly feel the ſentiments of benevolence, when he hears the good Titus exclaiming, that he had "loſt a day," becauſe he had done no perſon a good office in it! If a perſon be capable of forming any idea of greatneſs of mind in forgiving injuries, he will do it from hearing the following reply made by Lewis XII. to a courtier, who preſſed him to puniſh a perſon who had offended him before he came to the throne; "It belongs not to the king of France to revenge the injuries offered to the duke of Orleans?" Or, what can give ſo juſt an idea of the true ſpirit and magnanimity of a ſoldier, as the reply that viſcount Dorée made to Charles IX. of France, when he received an order from him to maſſacre the Huguenots; "I deſire your majeſty would employ me in what is *poſſible*." This example ſuggeſts alſo, that hiſtory enables us to form juſt ideas of the dignity and the weakneſs of human nature, both of which are extremely uſeful to us in life. When the earl of Peterborough, at the ſiege of Barcelona, was ſettling the terms of capitulation with the Spaniſh commander, news was brought him that, contrary to the ſuſpenſion of arms ſtipulated between them, a party of the allied troops had broken into the town. The earl, with a noble ſpirit of true honour and heroiſm, told the Spaniſh general, that if he would give him leave to enter the town with his Engliſh troops, he would drive out his allies, and then return to finiſh the capitulation, which he actually performed. Without mentioning the fabulous ſtory of Curtius, who is ſaid to have leaped into a gulph, or of Codrus, who procured his own death to ſave his country, we may obſerve, that at the ſiege of Turin one Mica fired a mine, and purpoſely deſtroyed himſelf with the enemy. And how many commanders of ſhips have blown them up rather than ſtrike their colours! Such facts, together with thoſe which manifeſt the extent of genius, in men like Ariſtotle, Archimedes, and ſir Iſaac Newton, give us high ideas of the dignity of human nature, and the capacity of the human mind. Hiſtory alſo, with equal fidelity, gives us a moſt affecting, and equally inſtructive view, of our deplorable weakneſs and frailty, exemplified in the occaſional conduct of the greateſt of men. What groſs and humiliating ſuperſtitions have been manifeſted by men, in other reſpects, of ſound and clear underſtandings, and of upright honeſt hearts! Paſcal, one of the greateſt geniuſes and beſt men that ever lived, entertained a notion, that God made men miſerable here in order to their being happy hereafter; and in conſequence of this notion, he impoſed upon himſelf the moſt painful mortification. He even ordered a wall to be built before a window in his ſtudy, which afforded him too agreeable a proſpect. He alſo had a girdle full of ſharp points next his ſkin, and while he was eating or drinking any thing that was grateful to his palate, he was conſtantly pricking himſelf, that he might not be ſenſible of any pleaſure. It was through a ſimilar weakneſs that the excellent Fenelon ſubmitted without reſerve to the arbitrary ſentence of the pope, when he condemned a book which he had publiſhed, and even preached in condemnation of his own book, forbidding his friends to defend it. (See the articles Fenelon and Paſcal.) Moreover, hiſtory tends to ſtrengthen the ſentiments of virtue, by the variety of views in which it exhibits the conduct of divine providence, and points out the hand of God in the affairs of men.

For whatever ſuggeſts to us the idea of a divine being, either in the end, or means, of great events, muſt be favourable to piety and virtue. Who would have imagined, that the deſire which Henry VIII. had to be divorced from his wife would have brought about the reformation in England? The indiſcretion of a Portugueſe prieſt, who would not give place to one of the king's officers in Japan, and the obſtinacy of the Jeſuits, in refuſing to give up the houſe which a nobleman had given them, when his ſon claimed it back again, occaſioned the extirpation of the Roman Catholic religion in that country. The hiſtory of Joſeph, that of Eſther and Mordecai, and many others that are recorded in the inſtructive pages of the Old Teſtament, ſupply facts to the ſame purpoſes. Great events, under the conduct of providence, are brought about contrary to the intention of the perſons who were the chief inſtruments of them, and by the means which were intended to produce a contrary event. Thus perſecution has been always the means of promoting the perſecuted religion; and thus the well-known adage has been verified: "The blood of the martyrs is the ſeed of the church." Thus, likewiſe, Athens, Lacedæmon, Carthage, Rome, and many other ſtates, have been ruined by their own ſucceſſes. Philip II. of Spain, by his intolerable oppreſſion, was the cauſe of the freedom of the ſtates of Holland. A regard to divine providence is alſo extremely uſeful to heighten our ſatisfaction in reading hiſtory, and throw an agreeable light upon the moſt gloomy and diſguſting parts of it. Moreover, hiſtory, in the miſfortunes and hardſhips to which the moſt diſtinguiſhed perſonages have been reduced, gives us a deep conviction of the inſtability of all human things, and prepares our minds to ſubmit to adverſity with more patience and reſignation, as to a condition from which we ſee none are exempt. What other ſenſation do we feel, while we read that Henrietta, daughter of Henry IV. of France, and wife to Charles I. of England, was reduced to the utmoſt poverty; and that her daughter, afterwards married to a brother of Lewis XIV. is ſaid to have lain in bed for want of coals to keep her warm, while the people of Paris, blind with rage, paid no attention to her ſufferings! Similar ſenſations are felt, when we read the hiſtory of Beliſarius, the great and ſucceſsful general, who is ſaid to have begged his bread, and of Cortez, the renowned conqueror of Mexico, who lived unknown and diſgraced in Spain, and was ſcarcely able to obtain an audience of his maſter, Charles V., though, when the king aſked who was the fellow that was ſo clamorous to ſpeak to him, he cried out, "I am one who have got your majeſty more provinces than your father left you towns." Beſides, the reverſes of fortune, and calamities of men in high ſtations, ſhould diſpoſe thoſe who have no opportunity of riſing above them, to be content with their ſituation. The many who have abdicated royalty, as Chriſtina, queen of Sweden, Charles V. emperor of Germany, Victor Amadeus, king of Sardinia, John Caſimir, king of Poland, and others, convince us that crowns do not always ſit eaſy; and that perſons in high ſtations have need of a ſtrong ſenſe of honour and integrity to make their fatigues and misfortunes tolerable. In many inſtances they are objects, not of envy, but of commiſeration; and they claim the exerciſe of a candid judgment. The examples of diſtinguiſhed perſonages are apt to make a deeper impreſſion on the mind than thoſe of perſons, ſubject to viciſſitude, in the humbler ſtations of life. The inſufficiency of power and riches to bound men's views and to make them happy, is evinced in a thouſand inſtances of almoſt daily occurrence; but the ſentiment makes a deeper impreſſion when we ſee it exemplified in the hiſtory of ſtateſmen and conquerors. It is beautifully exhibited in a converſation which paſſed between Pyrrhus and his miniſter Cyneas, before their expedition into Italy. The miniſter aſked the king what he propoſed to do when he had ſubdued the Romans? He anſwered, paſs into Sicily. What then? ſaid the miniſter. Conquer the Carthaginians, replied the king. And what follows that? ſays the miniſter. Be ſovereign of Greece, and then enjoy ourſelves, ſaid the king. And why, replied the ſenſible miniſter, can we not do this *laſt* now?

Beſides the benefits reſulting from the ſtudy of hiſtory, above briefly recited and illuſtrated, there are other advantages accruing to mankind from it, in a different manner, as only one inſtrument of recording tranſactions. How imperfect, *e. g.* without hiſtory, would be our knowledge of genealogies, and conſequently of the order of important ſucceſſions, and how precarious would be the advantage, reſulting from conventions and treaties of all kinds, if all the articles of them were repoſited only in the memory of the contracting parties. We read that the boundaries of the Grecian ſtates were once determined by a verſe of Homer, who, in his deſcription of Greece, relates what they were in his time.

If hiſtory be of ſuch diſtinguiſhed uſe, we may eaſily anſwer a queſtion that has been ſometimes propoſed; *viz.* at what age it is proper to be read. We need not heſitate in pronouncing, that it can neither be begun too early, nor continued too late. "If hiſtory amuſe the imagination, exerciſe and improve the paſſions, inſpire a taſte for true glory, juſt ſentiments of, and a love for, virtue, and thereby form the *temper,* and prepare man for converſing with the world; what can be more proper for young perſons? And ſince the mind cannot be too well furniſhed in theſe reſpects, and men cannot have too large a ſtock of this *anticipated experience,* the ſtudy of it muſt be uſeful, while there remains any thing of the part we have to act on the theatre of the world. Moreover, ſince hiſtory furniſhes materials for the fineſt ſpeculations, and the moſt important ſciences, it cannot but be of ſervice while we make any uſe of our intellectual faculties." Prudence will direct thoſe who have the conduct of the ſtudies of young perſons to make a proper ſelection. Hiſtories, which tend chiefly to amuſe the imagination, or enforce the plaineſt inſtructions in morals, ought rather to be recommended to perſons in early life; and hiſtories which furniſh greater exerciſe for the judgment ſhould be reſerved for an age in which the judgment is riper. However, there can be no great inconvenience in young perſons' being indulged in reading almoſt all hiſtories promiſcuouſly. No general hiſtory is better calculated for the uſe of ſuch than that of Rollin.

As to the advantages that reſult from the ſtudy of *eccleſiaſtical hiſtory,* they are *general* or *particular.* In a general view of them, the hiſtory of the church preſents to our view a variety of objects that are every way adapted to confirm our faith. When we contemplate, by the aid of it, the diſcouraging obſtacles, the united efforts of kingdoms and empires, and the dreadful calamities which Chriſtianity, in its very infancy, was obliged to encounter, and over which it gained an immortal victory, this will be ſufficient to fortify its true and zealous profeſſors againſt all the threats, cavils, and ſtratagems of profane and impious men; the great and ſhining examples, alſo, which diſplay their luſtre, more or leſs, in every period of the Chriſtian hiſtory, muſt have an admirable tendency to inflame our piety, and to excite, even in the coldeſt and moſt inſenſible hearts, the love of God and virtue. Thoſe amazing revolutions and events that diſtinguiſhed every age of the church, and often ſeemed to ariſe from ſmall beginnings and cauſes of little conſequence, proclaim, with a ſolemn and reſpectable voice, the empire of providence, and alſo the inconſtancy and vanity of human things. And among other numerous advantages that reſult from the ſtudy of eccleſiaſtical hiſtory, it is none of the leaſt, that we ſhall thus ſee the origin and occaſions of thoſe ridiculous rites, abſurd opinions, fooliſh ſuperſtitions, and pernicious errors, with which Chriſtianity is yet diſfigured in too many parts of the world. This knowledge will naturally lead us to a view of the truth in its beautiful ſimplicity, will engage us to love it, and render us zealous in its defence; not to mention the pleaſure and ſatisfaction that we muſt feel in reſearches and diſcoveries of ſuch an intereſting kind. But in a more particular view of this ſubject, thoſe who are appointed to inſtruct youth in the public univerſities, and alſo thoſe who are ſet apart for the ſervice of the church, will derive from this ſtudy the moſt uſeful leſſons of wiſdom and prudence, to direct them in the diſcharge of their reſpective offices. The inconſiderate zeal and temerity of ſome, pourtrayed in their pernicious conſequences, will teach circumſpection; and the miſtakes into which men of eminent merit and abilities have been betrayed will point out the errors to be avoided, and the ſacrifices to be made, in order to maintain peace and concord in the church; and, on the other hand, illuſtrious examples and ſalutary meaſures will furniſh a rule of conduct, a lamp to ſhew them the paths they muſt purſue. Beſides, if we except the arms which ſcripture and reaſon ſupply againſt ſuperſtition and error, nothing can enable us to combat them with more efficacy than the view of their deplorable effects, as they are repreſented to us in the hiſtory of the church. Moſheim's Eccl. Hiſt. vol. i. Introduction.

HISTORY is alſo uſed for a *Romance*, or a fabulous but probable relation of a ſeries of actions or adventures feigned or invented by the writer. See ROMANCE.

Such is the Hiſtory of the Civil Wars of Grenada, the Hiſtory of Don Quixote, the Ethiopic Hiſtory of Heliodorus, &c.

HISTORY, in *Painting*. See HISTORICAL *Painting*.

HISTRIA, a peninſula, N.E. of the gulf of Venice. The firſt inhabitants of this country were probably Thracians, or more anciently Celtes. The Greeks called the part of the Danube with which they were acquainted "Iſter," and it is probable that thoſe who peopled Hiſtria were more anciently known on the banks of the Iſter. The principal place of Iſtria was Pola.

HISTRIO, in the *Ancient Drama*, ſignified an actor or comedian; but more eſpecially a pantomime, who exhibited his part by geſtures and dancing. See PANTOMIME.

Livy informs us that the hiſtriones were brought to Rome from Etruria in the year of the city 391, Dec. i. lib. 7. See HISTER.

HISTRIO, in *Ichthyology*. See LOPHIUS *Compreſſus*.

HISTRIX, in *Zoology*. See HYSTRIX.

HIT, in *Geography*, a town of the Arabian Irak, on a river of the ſame name, which ſoon after joins the Euphrates; near it is a ſpring of naphtha and bitumen; 100 miles W. of Bagdad.

HITCH, on *Ship-board*, a word denoting a ſort of knot or nooſe, by which one rope is faſtened to another, or to ſome other object, and hence uſed for catching hold of any thing with a hook or a rope, and to hold it faſt. Thus, when the boat is to be hoiſed in, they ſay, hitch the tackles into the rings of the boat; and, when about to weigh anchor, hitch the fiſh-hook to the fluke of the anchor.

HITCH, in *Mining*, ſignifies a fault in ſome diſtricts, and has been defined to be a narrow fiſſure whoſe up-throw or down-caſt does not much exceed five feet; others have ſaid that a hitch never entirely ſeparates a coal-ſeam, or never deranges as much as its thickneſs: we believe, however, that the miners are not more conſiſtent or agreed on theſe diſtinctions, than in the meaning of near 70 names which they have among them for the highly curious phenomenon called a *fault*. See that article.

HITCHEL, the ſame with hatchel.

HITCHER, in *Nautical Affairs*, is a pole, armed with an iron point and hook, which is uſed on board of barges or boats for either pulling or ſhoving them to or off each other, or a wharf, ſhip, &c. On moſt canals pointed hitchers are prohibited to the boatmen, on account of the damage they do to the lining of puddle in the bottom of the canal to retain its water, as mentioned in our article CANAL.

HITCHIN, in *Geography*, a large and ancient market-town and pariſh in the hundred of Hitchin and Pirton, Hertfordſhire, England, is ſituated in a fertile valley, and ſurrounded by conſiderable eminences. It appears to have had its origin in the Saxon times, and was granted by Edward the Confeſſor to earl Harold, by the appellation Hitche. In the Doomſday book it is called Hiz, a name that, according to Chauncy, it received from the little river Hiz, which flows through it. At the period of making that ſurvey it belonged to the king, and was rated at five hides; two of which are deſcribed as lying "in monaſterio hujus villæ." Hitchin church is a handſome edifice of ſtone, occupying the ſcite of a more ancient fabric near the centre of the town, and apparently of the age of Henry VI. or Edward IV. The interior is ſpacious, and conſiſts of a nave, chancels, and ſide aiſles: its length is upwards of 150 feet; its breadth 67. The ſepulchral monuments are very numerous. An inſcription for ſir Robert de Kendale, knight, and three effigies greatly mutilated, which are now placed under windows of the north aiſle, are of more ancient date than the preſent ſtructure. The firſt or moſt weſtward of theſe effigies repreſents a knight croſs-legged, in chain armour; and was probably deſigned for one of the Baliols, who were lords of this manor during the 12th and 13th centuries. The other two figures are the effigies of ſir Edward de Kendale, knight, lord of Hitchin, and his lady, who both died towards the end of the reign of Edward III. Some very fine braſſes, of the 15th and 16th centuries, occur in different parts of the church; and the windows contain much painted glaſs. At a ſhort diſtance ſouth-eaſt of the church was formerly the priory of Biggin, founded for nuns of the Gilbertine order; but at what period is uncertain. The ſcite is now occupied by the ſchool-houſe, and the appendant-eſtate is veſted in truſtees for charitable uſes. Hitchin priory was founded for white Carmelites in the time of Edward II.: very few traces of it remain; on the immediate ſcite is now a family manſion. The market at Hitchin, held on Tueſdays, has exiſted from an early period, and very large quantities of wheat and other grain are ſold in it; probably in ſome degree from being free of toll, by preſcriptive right. Two fairs are held annually for the ſale of cattle, ſheep, &c. Formerly the wool trade was very flouriſhing here; this town having become the reſidence of many merchants on the removal of the ſtaple from Calais by Edward III. The town is divided into three wards, *viz.* Bancroft, Bridge, and Tilehouſe wards, and is governed by a bailiff, four conſtables, and two headboroughs for each ward. Among numerous charitable donations in this pariſh, are thoſe of John Skynner, gent. who, in the year 1668, beſtowed 300*l.* to build almſhouſes; 300*l.* to purchaſe lands for their endowment; 100*l.* to apprentice poor children; and 100*l.* towards the further endowment of the free-ſchool. Hitchin is 34 miles diſtant from London: and, according to the returns under the population act of 1801, contained 674 houſes (moſtly irregular buildings),

buildings), and 3161 inhabitants. Chauncy's Hiſtorical Antiquities of Hertfordſhire.

HITCHING, in *Horſemanſhip*, is to wriggle or move forwards by degrees, or to knock the legs together in walking.

HITHE, in *Geography*. See HYTHE.

HITSACKER, a town of the principality of Luneberg-Zelle, ſituated on an iſland in the Jetze; 29 miles E. of Luneburg. N. lat. 53° 17'. E. long. 14° 12'.

HITTERO, or HITTEREN, an iſland in the Northern ocean, near the coaſt of Norway. N. lat. 63° 32'. E. long. 8° 20'.

HIU, a city of China, of the ſecond rank, in the province of Honan. N. lat. 34° 5'. E. long. 113° 35'.

HIVE, in *Rural Economy*, the name of a well known repoſitory for bees. Bee-hives, in different places, and on different occaſions, are of very different materials. In ſome places the hollow trunk of a tree ſerves the purpoſe; in others they are made of four boards nailed together in the ſhape of a long box, and placed with one end upon the ground, or upon a frame of wood-work erected for that purpoſe. The moſt uſual form of them, however, is conic and bell-faſhioned; and the common materials of which they are made are twiſted oſier or ſtraw, nicely matted together, and made into a ſort of thick cords, bound round with oſier-bark. The laſt is the moſt common kind, and ſerves perfectly well for all the purpoſes of the bees, and of the perſons who make their profits of the honey. The lodgment is ſufficiently warm and cloſe for the bees, and a thin frame of boards defends it from being injured by the wet. But perſons of ſpeculative diſpoſitions have at all times been deſirous of ſeeing what paſſed in the hive, and of obſerving theſe induſtrious inſects at their work: for this purpoſe the ancients contrived a method of placing certain ſquares or panes of a tranſparent matter, ſuch as horn, or the lapis ſpecularis, or iſinglaſs, in ſome parts of the ſides of the hive, through which they might ſee all that paſſed within. This is mentioned by Ariſtotle, Pliny, and others; but it ſoon ſunk into diſuſe, and in later ages it has been ſuppoſed to be an idle attempt. Mouffet in particular ridicules it, and ſays, that the bees within would immediately ſpoil the tranſparence of any materials thus employed.

This practice of the ancients ſeems to have been firſt revived in our country by Mr. Jeddie, who, in the year 1665, publiſhed his invention of boxes for preſerving the lives of bees, and obtained a patent from king Charles. Theſe were improved by Joſeph Warder, phyſician at Croydon, who enriched his account of the ſtructure and uſe of theſe boxes, with ſeveral other curious circumſtances concerning bees, in his work entitled "The true Amazons, or the Monarchy of Bees." But this method was far from being generally known in the year 1680, ſince Swammerdam ſeems to have been altogether unacquainted with it; and to this we are to impute the imperfections of that author's account of bees, becauſe, though a moſt accurate and faithful writer, he had no opportunities of ſeeing what has been ſince diſcovered with this advantage.

Of late, however, this invention has been commonly practiſed. A tranſparent ſort of bee-hive may eaſily be made, by leaving certain ſquares in a wooden hive open, and afterwards faſtening clear glaſs in theſe vacant ſpaces; a frame of wood may cover the whole, ſo that the light is not always let in upon the bees, and the covering may be removed when the obſerver is to examine their operations. By this means it is found, that the ſquares of glaſs, when properly placed, will keep clean and tranſparent for many years; and when they are ſullied, there are eaſy methods of cleaning them, by taking them out and replacing them when they have been wiped. When the obſerver places himſelf behind the hive, and has one of theſe ſquares of glaſs before his eye, he ſees exactly all that paſſes within, without incommoding or interrupting the creatures at their work. Theſe glaſs hives, however, are chiefly objects of curioſity, though, in ſome inſtances, they have led to diſcoveries that muſt gradually contribute to the improvement of the economy of theſe uſeful inſects.

The principal advantage derived from hives of modern conſtruction, is that of obtaining the honey and wax without recurring to the barbarous expedient of deſtroying the bees. In the common method, a hole is dug near the hive, (generally in the month of September,) and a ſtick, at the end of which is a rag that has been dipped in melted brimſtone, is fixed in the hole; and, when the rag is ſet on fire, the hive is immediately put over it, and the earth thrown up round it, ſo that none of the ſmoke can eſcape; and thus the bees are inhumanly and needleſsly deſtroyed. The heavieſt and lighteſt hives are treated in this manner; the former, becauſe they yield the greateſt profit, with an immediate return; and the latter, becauſe the bees in them would not be able to ſurvive the winter. Thoſe hives which weigh from fifteen to twenty pounds are thought to be the fitteſt for keeping. The method of preſerving the lives of bees has been brought to a conſiderable degree of perfection by the late Mr. Thorley of Oxfordſhire, and Mr. White of Suffolk. Mr. Thorley, who takes the lead in this improvement, prefers colonies to hives for the following reaſons: 1. The more certain preſervation of many thouſands of theſe uſeful inſects. 2. Their greater ſtrength, conſiſting in their number, and their correſponding ſecurity from robbers. 3. Their greater wealth, ariſing from their united labours. To this purpoſe he tells us, that he has, in ſome ſummers, taken two boxes filled with honey (moſt of it being pure virgin honey of the beſt kind) from one colony, and left ſufficient ſtore for their maintenance: add to theſe advantages, the pleaſure of viewing them, with the greateſt ſafety, at all ſeaſons, even in their buſieſt time of gathering, and their requiring much leſs attendance in ſwarming time. The bees thus managed are alſo more effectually ſecured from wet and cold, from mice, and other injuries.

Mr. Thorley's boxes are made of deal, which, being ſpongy, ſucks up the breath of the bees ſooner than a more ſolid wood would do; and yellow dram-deal, thoroughly ſeaſoned, he ſays, is the beſt.

The beſt form of theſe boxes is an octagon, which, being nearer to a ſphere, allows the bees in winter to lie in a round body near the centre of the hive; and thus a due heat is conveyed to all the exterior parts, and the honey is kept from candying. The dimenſions, which he recommends, after long trial, are ten inches deep in the inſide, the top-board a full inch, and the breadth within twelve or fourteen inches. He has tried boxes containing a buſhel or more, but found them not to anſwer the deſign like thoſe of a leſs ſize. The top of the box ſhould be made of an entire board, or of two boards well glued together, which ſhould be a full inch thick after it has been planed, and project on all ſides at leaſt an inch beyond the dimenſions of the box. In the middle of this top there muſt be a hole five inches ſquare, for a communication between the boxes; and this hole ſhould be covered with a ſliding ſhutter of deal or elm, running eaſily in a groove, over the back-window. The eight pannels, nine inches deep, and three quarters of an inch thick when planed, are to be let into the top, ſo as to keep them in their proper places; to be ſecured at the corners with plates of braſs, and to be cramped with wires at the bottom, in order to keep them firm. There ſhould be a glaſs window behind, fixed in a frame, with a thin deal cover, two ſmall braſs hinges, and a button to faſten it: this window will ſerve for inſpecting the ſtate and operations of the bees. Two braſs handles, one on each ſide, are neceſſary to lift up the box; theſe ſhould be fixed in with two thin plates of iron, near three inches long, ſo as to turn up and down with the box, and put in three inches below the top-board, which is nailed down cloſe with ſprings to the other parts of the box. Thoſe who chooſe a frame within, to which the bees may faſten their combs, need only uſe a couple of deal ſticks of an inch ſquare, placed acroſs in the box, and ſupported by two pins of braſs; one an inch and a half below the top, the other two inches below it; by which means the combs will quickly find a ſtay. There muſt alſo be a paſſage, four or five inches long, and leſs than half an inch deep, for the bees to go in and out at the bottom of the box.

The boxes, thus prepared, ſhould be kept in a houſe, or under a ſhed, the diſpoſition and ſtructure of which Mr. Thorley has particularly deſcribed. He alſo recommends to paint the apertures of the boxes, which are the habitations of the ſeveral colonies, with different colours, as red, white, blue, yellow, &c. in form of a half-moon or ſquare, that the bees may the better know their own home. For the method of furniſhing theſe colonies with inhabitants, ſee HIVING.

Mr. Thorley, ſon to the above-mentioned gentleman, has, by long experience, improved his father's method of managing bees. The bee-hive of his conſtruction, preſented to the Society of Arts, &c. is exhibited in *Plate* XX. *Miſcellany, fig.* 1.

The bottom part, marked *a*, is an octangular bee-box, made of deal-boards, about an inch in thickneſs, the cover of which is externally 17 inches in diameter, but internally only 15½, and its height 10 inches. In the middle of the cover of this octangular box is a hole, which may be opened or ſhut at pleaſure, by means of a ſlider *d*. In one of the pannels is a pane of glaſs, covered with a wooden door *e*. The entrance *f*, at the bottom of the box, is about three and a half inches broad, and half an inch high. Two ſlips of deal about half an inch ſquare, croſs each other in the centre of the box, and are faſtened to the pannel by means of ſmall ſcrews: to theſe ſlips the bees faſten their combs. In this octangular box the bees are hived, after ſwarming in the uſual manner, and there ſuffered to continue till they have built their combs and filled them with honey; which may be known by opening the door, and viewing their works through the glaſs pane, or by the weight of the hive.

When the bee-maſter finds his laborious inſects have filled their habitation, he is to place a common bee-hive of ſtraw, repreſented at *b*, made either flat at the top, or in the common form, on the octangular box, and drawing out the ſlider, a communication will be opened between the box and the ſtraw hive; in conſequence of which the bees will fill this hive alſo with the product of their labours.

When the ſtraw hive is well filled, the ſlider may be puſhed in, and the hive taken away, and another placed in its room, with the ſlider drawn out. This new hive will alſo be filled in the ſame manner.

By proceeding in this method, Mr. Thorley aſſured the ſociety, that he had taken three ſucceſſive hives filled with honey and wax, from a ſingle hive, during the ſame ſummer, and that the food ſtill remaining in the octangular box was ſufficient for the ſupport of the bees during the winter. He adds, that if this method was purſued in every part of the kingdom, inſtead of the cruel method of deſtroying theſe uſeful inſects, he is perſuaded, from long experience, that wax would be collected in ſuch plenty, that candles made with it might be ſold as cheap as thoſe of tallow are ſold at preſent.

Mr. Thorley has alſo added another part to his bee-hive, which cannot fail of affording the higheſt entertainment to a curious and inquiſitive mind. This part conſiſts of a glaſs receiver, 18 inches high, eight inches in diameter at the bottom, and in the greateſt part 13; this receiver has a hole at the top, about an inch in diameter, through which a ſquare piece of deal is extended nearly to the bottom of the veſſel, having two croſs-bars, to which the bees faſten their combs. Into the other end of this ſquare piece is ſcrewed a piece of braſs, which ſerves for a handle to the receiver or glaſs hive. When the bees have filled their ſtraw hive, which muſt have a hole in the centre covered with a piece of tin, Mr. Thorley places the glaſs receiver upon the top of the ſtraw hive, and draws out the piece of tin. The bees, now finding their habitation enlarged, purſue their labours with ſuch alacrity, that they fill this glaſs hive likewiſe with their ſtores; and as this receptacle is wholly tranſparent, the curious obſerver may amuſe himſelf with viewing the whole progreſs of their works. It will, however, be neceſſary to cover the glaſs with an empty hive of ſtraw, or at leaſt with a cloth, which may be eaſily removed when the bees are inſpected, leſt too much light prevent their working. In this way Mr. Thorley, in a good ſeaſon, has had a glaſs filled in thirty days, containing 38 pounds of fine honey.

When the glaſs is completely filled, ſlide a tin plate between the glaſs and the hive or box, ſo as to cover the paſſage, and in half an hour the glaſs may be taken away with ſafety. The few bees that remain will readily go to their companions.

Mr. Thorley has added a glaſs window to his ſtraw hives, in order to obſerve the progreſs of the bees; and this contrivance is uſeful, eſpecially if one hive is to be removed whilſt the ſeaſon continues favourable for their collecting of honey; for when the combs are filled with honey, the cells are ſealed up, and the bees forſake them, and reſide moſtly in the hives in which their works are chiefly carried on. Obſerving alſo, that the bees were apt to extend their combs through the paſſage of communication into the upper hive, which rendered it neceſſary to divide the comb when the upper hive was taken away, he puts in that paſſage a wire ſcreen for netting, the meſhes of which are large enough for a loaded bee to paſs eaſily through them; and thus he prevents the junction of the combs from one box to the other, and conſequently obviates the neceſſity of cutting them, and of ſpilling ſome honey, which running down among a crowd of bees, incommoded them much.

Mr. White, in his directions for making the bee-boxes of his invention, tells us, ſpeaking of the conſtruction of a ſingle box, that it may be made of deal or any other well-ſeaſoned boards, which are not apt to warp or ſplit. The boards ſhould be near an inch thick; the figure of the box ſquare, and its height and breadth nine inches and five-eighths every way, meaſuring within. A box of theſe dimenſions will contain near a peck and a half. The front part muſt have a door cut in the middle of the bottom edge, three inches wide, and near half an inch high. In the back part a hole muſt be cut with a rabbet in it, in which is to be fixed with putty a pane of the cleareſt and beſt crown glaſs, about five inches long, and three broad; and let the top of the glaſs be placed as high as the roof withinſide, that the upper part of the combs may be ſeen; and thus the ſtate and ſtrength of the bees may be judged better of than if the glaſs were fixed in the middle. The glaſs muſt be covered with a thin piece of board, as a ſhutter, which may be made to hang by a ſtring, or turn upon a nail, or ſlide ſideways between two mouldings. The glaſs may be made large, or another pane of glaſs may be fixed on the top and covered with a ſhutter, for the convenience of obſerving the bees at their work. The ſide of the box, which is to be joined to another box of the ſame form and dimenſions, as it will not be expoſed to the external air, may be made of a piece of ſlit deal not half an inch thick. This Mr. White calls the ſide of communication, becauſe it is not to be wholly incloſed: a ſpace is to be left or cut at the bottom through the whole breadth of the box, and a little more than an inch in height, and a hole or paſſage is to be made at the top, three inches long, and more than half an inch wide. Through theſe the bees are to have a communication from one box to another. In the next place a looſe board is to be provided, which board is to be half an inch thick, and large enough to cover the ſide of communication; and likewiſe ſeveral little iron ſtaples, an inch and a half long, with the two points or ends bending down more than half an inch: the uſe of this part of the apparatus will appear under the article Hiving. Moreover, let two ſticks be fixed in the box tranſverſely and croſſing each other, in order to be a ſtay to the combs; one about three inches from the bottom, and the other at the ſame diſtance from the top; and when the hole is painted, in order to render it more durable, the box is finiſhed. This box, ſays the inventor, is as plain as poſſible: it is little more than five ſquare pieces of board nailed together, ſo that any poor cottager may make his own boxes, without the help or expence of a carpenter.

The other box muſt be exactly of the ſame form and dimenſions; and the two boxes differ only in this, that the ſide of communication of the one muſt be on the right hand, and of the other on the left. The two boxes, with their openings of communication ready to be joined to each, are repreſented in *Plate* XX. *Miſcellany*, *fig.* 2.

In *fig.* 3, is exhibited the front of a frame for twelve colonies; *a*, *a*, are two ſills of oak, lying flat on the ground, more than four feet long: in theſe ſills are fixed four oaken poſts, about the thickneſs of ſuch as are uſed for drying linen. The two poſts *b*, *b*, in the front, are about ſix feet two inches above the ſills; the other two, ſtanding backward, five feet eight inches. You are next to nail ſome boards of ſlit deal horizontally from one of the fore-poſts to the other, in order to ſcreen the bees from the ſun: let theſe boards be ſeven feet ſeven inches in length, and nailed to the inſide of the poſts, and be well-ſeaſoned, that they may not ſhrink or gape in the joints: *c*, *c*, are two ſplints of deal, to keep the boards even, and to ſtrengthen them.

Fig. 4, repreſents the back of the frame: *d*, *d*, *d*, *d*, are four ſtrong boards of the ſame length with the frame, on which the boxes are to be placed; let the upper ſide of them be very ſmooth and even, that the boxes may ſtand true upon them, or it may be more adviſeable to place under every pair of boxes a ſmooth thin board, as long as the boxes, and about a quarter of an inch wider. The bees will ſoon faſten the boxes to this board in ſuch a manner, that you may move or weigh the boxes and board together, without breaking the wax or reſin, which, for many reaſons, ought to be avoided.

Theſe floors muſt be ſupported by pieces of wood or bearers, *e*, *e*, &c. which are nailed from poſt to poſt at each end: they are likewiſe to be well nailed to the frame, to keep them from ſinking with the weight of the boxes: *f* repreſents the roof, which projects backwards about ſeven or eight inches beyond the boxes, to ſhelter them from the rain.

You have now only to cut nitches or holes in the frame over-againſt every entrance into the boxes, as *h*, *h*, *h*, *fig.* 3, let theſe nitches be near four inches long, and under each nail a ſmall piece of wood for the bees to light upon. The morning or evening ſun will ſhine upon one or both ends of the frame, let its aſpect be what it will; but you may prevent its over-heating the boxes, by a looſe board ſet up between the poſts, and kept in by two or three pegs.

In order to take away part of the honey, without deſtroying or much diſturbing the bees, Mr. White adviſes to examine the ſtate of the colonies about the latter end of Auguſt through the glaſſes; and he obſerves, that ſuch as have filled a box and a half with their works may ſpare the half box; but the honey-comb ſhould be particularly examined, and about eight or nine pounds left for their winter ſtore. When this is done, open the mouth of the box you intend to take; then, with a thin knife, cut through the reſin with which the bees have joined the boxes to each other, till they are ſeparated; and, after this, thruſt a ſheet of tin gently between the boxes. The communication being thus ſtopped, the bees in the fulleſt box, where moſt probably the queen is, will be a little diſturbed; but thoſe in the other box, where there is no queen, will be in the utmoſt confuſion, running to and fro with a kind of mournful cry, and iſſuing out at the newly opened door in great diſorder: however, when they have got abroad, and diſcover their companions, they eagerly join them at the mouth of the other box. By this means, in an hour or two, you will have a box of pure honey, without a living bee to moleſt you, or any dead bees to waſte or damage the honey.

Mr. White's boxes are convenient for feeding poor ſtocks, in order to preſerve them, and alſo for removing moths and inſects from any colony that is in danger of being injured by them.

Mr. Wildman recommends the following method of taking the wax and honey, without deſtroying the bees: remove the hive, from which you would take the wax and honey, into a room, into which little light is admitted: invert the hive gently, placing it on any ſupport, and cover it with an empty hive, keeping the ſide next the window of the empty hive raiſed a little, to give the bees ſufficient light to find their way into it; while you hold the empty hive ſteadily ſupported on the edge of the full hive, between your ſide and your left arm, keep ſtriking with your hand all round the full hive from top to bottom, in the manner of beating a drum, ſo that the bees may be frightened by the noiſe, and mount out of the full hive into the empty one. As ſoon as all the bees are out of the full hive, which will generally be in about five minutes, the other hive, in which they are collected, muſt then be placed on the ſtand from which the full hive was taken, in order to receive the abſent bees as they return from the fields.

If this be done early in the ſeaſon, the operator ſhould examine the royal cells; for if any of them contain young bees, they, as well as all the combs that have young bees in them, muſt be preſerved in the hive. Take out the other combs with a long, broad, and pliable knife, cutting them from the ſides and crown as clear as poſſible, to prevent the future labour of the bees, who muſt lick up all the honey ſpilt, and remove every grain of wax. The ſides of the hive ſhould then be ſcraped with a table ſpoon, to clear away what was left by the knife.

Having thus taken the wax and honey, let a table, covered with a clean cloth, be placed near the ſtand, and giving the hive, in which the bees are, a ſudden ſhake, ſtriking at the ſame time with a conſiderable degree of force, the bees will be ſhaken on the cloth. Put their own hive upon them immediately, raiſed a little on one ſide, that the bees may the more eaſily enter; and when all are entered, place it on the ſtand as before. If the hive in which the bees are be turned uppermoſt, and their own hive placed over it, the bees will immediately aſcend into it, eſpecially if the lower ſide be ſtruck to alarm them; for the effects of fear, impreſſed on the bees by the continual noiſe, renders them, for a conſiderable time, ſo mild and tractable, that they will bear any handling, which does not hurt them, without any ſigns of reſentment.

Mr. Thorley objects to the method of driving bees, in order to obtain their honey, becauſe the honey will be foul and corrupted, and great numbers of the young brood will thus be utterly deſtroyed, and the ſtocks much reduced and endangered.

Mr. Iſaac, ſecretary to the Apiarian Society in the weſt of England, has publiſhed a ſmall treatiſe, entitled "The General Apiarian," in which, among other things, he has deſcribed the ſtructure of two hives, one called the "Moreton Hive," and the other the "Cottage Hive." The former is intended for a houſe or ſhed, and the latter for the open garden. The Moreton-hive is made of reed, ſtitched with the ſplits of willow or bramble; it is of a cylindric form, twelve inches clear in diameter, and ſix inches high; it is beſt made upon a narrow hoop with whimble bit-holes in it to receive the ſtitches of the firſt liſt or round of reed, and a mortiſe-hole in the fore-part for entrance, $2\frac{1}{2}$ inches in horizontal length by $\frac{1}{4}$th of an inch in perpendicular height: this entrance ſhould be near $\frac{1}{4}$th of an inch above the lower edge of the hoop, which edge ſhould be ſo planed as in every part to touch a plain board. The hive, thus conſtructed, ſhould be laid upon a level board, with another board upon it, which ſhould be ſo thick as not to bend under a weight of 56 pounds, which ſhould remain upon it for a day or two, till it is ſettled in a cloſe ſtate. When the hive is taken off, two of the middle liſts ſhould be cut oppoſite to the entrance for receiving a pane of glaſs, near three inches long, and as wide as the part of the two liſts taken out. The ends of the liſts, or coils, ſhould be ſecured by ſtitches made with ſoftened mole-ſnap wire. When the glaſs is faſtened with putty, the ſtitch-holes of the hoop ſhould be filled with the ſame; and then a ſmall ſtick ſhould be made to paſs *in* through the middle liſt from right to left, and *out* at the other ſide of the hive to ſerve as a ſupport for the combs. This hive ſhould have a ſet of bars cut in a round deal board, 14 inches in diameter, and $\frac{1}{2}$ an inch thick, nearly rounded to fit the hive. Of theſe bars there are ſix, and their width is $1\frac{3}{8}$ths of an inch. The openings between them, called "ſtreets," muſt be $\frac{1}{2}$ an inch wide, and extend to within an inch of the circumference of the board, which by theſe openings is converted into bars to ſupport the combs. Acroſs theſe bars, on the under ſide, it may be right to ſpring a ſmall ſtay of wood, to keep them from dividing farther, in caſe the circumference ſhould ſplit at any time. The bars muſt be faſtened on the top of the hive with deal pins, entering through the firſt into the ſecond or third liſt; then a round flat top of reed, 14 inches in diameter, muſt be faſtened to them: in this cover, and near the front of the hive, the curious may have a hole made, five inches in diameter, covered by a ſmall board, which may be turned off at pleaſure, for placing over the hole a bell-glaſs, in which the bees may, in a good ſummer, be tempted to work. For a good ſwarm there ſhould alſo be provided two other hives, with bars of the ſame ſort; but without a top. On the bars of one of them the firſt hive ſhould be placed, with the glaſſes or windows, entrances and bars, perpendicularly over each other. There ſhould alſo be four hoops, of mole-ſnap wire, faſtened about nine inches aſunder, in one of the liſts of the under hive, through which to paſs a cord over the top hive, to keep both firmly together till the ſwarm is hived and placed in the bee-houſe. It is the cord that muſt keep them together. When the bees have filled the firſt and ſecond, let them be raiſed on the third.

The "Cottage-hive" is compoſed of two parts; the higher part is like the common hives, but ſomewhat leſs in dimenſions; $11\frac{1}{4}$ inches within, from the centre of the crown to the edges; the diameter at the edges is $13\frac{1}{4}$ inches; the entrance is horizontally two inches long, and $\frac{1}{4}$ of an inch high; oppoſite to the entrance, three liſts above the edge or ſkirt is a pane of glaſs, like that in the Moreton-hive, and acroſs the line of viſion from the glaſs to the entrance, a ſtick is paſſed *in* at the right and *out* at the left. The other part is the ſection of a cone, $13\frac{1}{4}$ inches diameter in the clear, at the higher edge, and $11\frac{1}{4}$ inches at the lower edge, or mouth, which is formed by a hoop, like the Moreton-hive, with the firſt liſt ſewed in the holes of it with willow or bramble ſplits. Over the entrance is a piece of ſloped deal, tacked to the hoop and front of the hive, to make it ſuit the front of the ſhed, or bee-houſe; but this piece ſhould not be united to it when it is to ſtand in the garden. Oppoſite to the entrance is the window for inſpection. But this part, called a "tranſit," becauſe it ſerves as a paſſage between a common hive and one of Wildman's hives, wants no croſs-ſtick to ſtrengthen the combs, as it is two inches wider at the higher than it is at the lower edge or bottom. On the higher edge of the tranſit there muſt be fixed bars, made of a round deal board, $\frac{1}{2}$ an inch thick, and $15\frac{1}{4}$ inches in diameter. The bars are 6, $1\frac{3}{8}$ inch wide; the ſtreets are five, half an inch wide, and there are two outſide ſtreets $\frac{3}{4}$ths of an inch wide, or rather more. The tranſit, when the bars are fixed, ſhould be preſſed by the weight of half a hundred, on a ſmooth ſtrong board, for a day or two, to ſettle it. The perpendicular height of the tranſit is about eight inches; and it will hold as much as the Moreton-hive. The two parts of the cottage-hive muſt be faſtened together, like the firſt and ſecond Moreton-hives, to receive the bees; and when the ſecond parts are united, it will hold nearly ſeven gallons. This is called the cottage-hive, becauſe it is the cheapeſt ever ſeen by the inventor, as it is of ſufficient dimenſions for the largeſt ſwarm, will admit of being eaſily divided and deprived, and may be reduced to accommodate a ſmall or poor ſtock, by taking off the under part againſt winter; and by means of a good cap, hoop, and cord, it may be ſecured on an open ſtand, firmly fixed on the ground, againſt all the common aſſaults of wind and weather. Its form, being nearly that of an egg, with a part of the ſmall end cut off, is more friendly to the bees, in reſpect to warmth in winter, and, therefore, better calculated for breeding in the ſpring than any other. It poſſeſſes all the advantages, without the inconveniences, of the large hive, recommended by the ingenious Mr. Butler, the father of the Engliſh Apiarians.

See on the ſubject of this article, Thorley's Inquiry into the Nature, Order, and Government of Bees, 1774; White's Collateral Bee-Boxes; Wildman, &c. on Bees; Key's Ancient Bee-Maſter's Farewell, 1796; Iſaac's General Apiarian, 1803. See BEE.

Hive *droſs*, a name ſometimes given to crude or rough wax. See Wax.

HIVING, the placing of a ſwarm of bees in a hive, in order to have the profit of their labours. When the ſwarm of bees has left an old hive, and is placed in form of a cluſter hanging down from the branch of ſome ſhrub or low buſh, the hiving is extremely eaſy, and may be done in half an hour after the time of their being ſtill and calm in the cluſter; or it may be let alone till an hour or two before ſunſet, provided that the ſun do not ſhine too vehemently upon the place where they are, for that would diſquiet them, and force them to riſe; and, in that caſe they uſually take a long flight before they ſettle again, and are very often loſt; this, however, may at any time be prevented by placing an artificial ſcreen before them, compoſed either of coarſe cloth, or of a few branches of trees well covered with leaves.

It is commonly the branch of ſome ſhrub or tree that they ſettle upon, and we always find that they mean this as their ſettled habitation; for, however ſoon they are hived, the rudiments and beginnings of combs are found on it. It is true, they always leave theſe places, if left to themſelves, in five or ſix days; but this is not till they find them ſo inconvenient that they cannot keep them, either from their being too much ſcorched by the ſun, or expoſed to winds and rain. The quantity of wax and honey left in theſe places, when they have quitted them, abundantly proves, however, that they had meant them for their fixed abode.

When they are placed in a hive, they very ſoon find themſelves much better lodged than in the place they had provided for themſelves; and they uſually ſtay in it, and begin to work the next morning.

It might appear a very difficult taſk to get ſo large a number of bees into a hive, but it is much leſs ſo than it appears to be. They will often take poſſeſſion of the hive of their own accord when it is hung over them; but the ſhorteſt way is to hold the hive under the branch where they are, and then ſweep them down into it. This may be done with a branch of a tree with its leaves on it, or with the hand armed with a ſtrong glove, and the face covered. But there are country fellows who will go without any ſort of defence, and with their naked hand ſweep them carefully off the bough into the hive, which they hold in the other hand underneath.

It is not to be expected that the whole ſwarm will be thus ſwept peaceably into the hive; many will fly away, and many cluſters will fall beſide the hive to the ground. All this, however, creates no difficulty; for the hive being turned bottom upwards, and ſet on the ground near the tree, with its edges a little raiſed above the ſurface, thoſe bees which fell in cluſters to the ground will ſoon crawl to their companions in the hive, and ſoon after, thoſe which flew off, will deſcend and follow their example. If it happen, however, that ſome bees will obſtinately keep to the place where they at firſt fixed themſelves, the branch is to be rubbed over with the juice of ſuch plants as the creatures hate the ſmell of; ſuch are elder, rue, and ſome others; and if this does not ſucceed, there muſt be linen rags burnt under them, the ſmoke of which will ſoon drive them off, and make them join their companions, who find themſelves more at eaſe in the hive.

As it is neceſſary to render the places diſagreeable to the bees from which they are to be taken into the hive, ſo, many people think it very proper to prepare the hive for their reception, by ſcenting it with ſuch things as they love the ſmell of. To this purpoſe they rub the inſide of it with baum and bean-flowers, and daub a little honey in ſome parts of it. This, however, does not ſeem neceſſary, thoſe hives having been found to ſucceed full as well where it was not done, as thoſe where it was. Reaumur's Hiſt. Inſ. vol. x. p. 205.

Another method of getting a ſwarm from a branch of a high tree, is to cut off the branch with a ſaw, as gently and with as little diſturbance to the bees as poſſible. In this caſe, when the branch is off, a man may carefully deſcend with it, and the bees will not quit their hold, but will be all carried where he pleaſes with it, and may by that means be very eaſily put into a hive.

Sometimes the bees, which go out in a ſwarm, fix upon a hole in a wall, or a hollow in the trunk of a tree, for the aſſembling themſelves. This is a much better choice for them than the branch of a tree, but it is much worſe for the perſon who is to hive them, for they are very difficult to be got out of theſe places. The common way of the country people is to attack theſe ſwarms in the middle of a cold night, and then they enlarge the opening from without, and placing the hive under it, ſcoop the bees out of their neſt with a ladle, and put them into the hive.

Mr. Thorley tells us, that the beſt time to plant colonies of bees is either in March or April with new ſtocks, or in May or June with ſwarms. If ſwarms are uſed, procure, if poſſible, two the ſame day, and put them together in two boxes, or in a hive and a box; at night place them in your houſe, and with a knife and a little lime and hair, ſtop cloſe the mouth of the hive or upper box, ſo that not a bee may be able to go in, or out, except at the front door. If boxes are employed, you will, in a week or ten days, ſee the combs appear in them; but in a hive nothing can be obſerved till the bees have wrought down into the box. Never plant a colony with a ſingle ſwarm, as Mr. Thorley ſays he has ſometimes done, but with little ſucceſs.

When the ſecond box, or the box under the hive, appears full of bees and combs, it is a proper time to raiſe the colony in the duſk of the evening, which ſhould be done in the following manner: place your empty box, with the ſliding ſhutter drawn back, behind the houſe, near the colony that is to be raiſed, and at nearly the height of the floor, by the help of another empty box upon the ground; then lifting up the colony with as much expedition as poſſible, ſet it down upon the empty box, with the aperture of the colony cloſe to the piece of wood nailed upon it, ſo that no ſingle bee may get out: when this is done, lift the hive and two boxes, or the three boxes, into the houſe again, putting them in their proper place.

Mr. Thorley farther adds, that the moſt effectual method of preſerving bees in common hives is, incorporating or uniting two ſtocks into one, by the help of a peculiar fume or opiate, which will put them entirely in your power for a time, ſo that you may diſpoſe of, and diſtribute them at pleaſure. The queen, in this operation, is immediately to be ſearched for and detained. Hives or ſtocks, which have ſwarmed once or twice, and are conſequently reduced in their number, are the fitteſt to be joined together, as they will be thus greatly ſtrengthened and improved. However, if you have a ſtock both rich in honey and full of bees, you may take it, by dividing the bees into two parts, and putting them into two other hives inſtead of one. But be careful to examine, whether the ſtock to which you deſign to join the bees of another, has honey enough to maintain the bees of both; for which purpoſe it ſhould be full twenty pounds in weight.

The ſtupifying fume uſed in this proceſs is the fungus maximus or pulverulentus, or large muſhroom, commonly known by the name of bunt, puckfiſt, or frog-cheeſe: it is as big as a man's head, or bigger: when ripe, it is of a brown colour, turns to powder, and is exceeding light. Put one of theſe pucks into a large paper, preſſing it to two-thirds or nearly half its bulk, and tying it very cloſe; then place it in an oven ſome time after the houſhold bread is drawn, and let it remain there all night; when it is dry enough to retain fire, it is fit for uſe in the following manner: cut off a piece of the puck as large as a hen's egg, and fix it in the end of a ſmall ſtick ſlit for the purpoſe, and ſharpened at the other end, and place this ſo that it may hang near the middle of an empty hive; this hive muſt be ſet with the mouth upward, in a pail or bucket, near the ſtock you intend to take: then ſet fire to the puck, and immediately place the ſtock of bees over it, tying a cloth round the hives, that no ſmoke may eſcape. In a little while you will hear the bees fall like drops of hail into the empty hive. You may then beat the top of the hive gently with your hand, to get as many out as you can: after this, looſening the cloth, lift off the hive to a table, knock it ſeveral times againſt the table, and ſeveral more bees will tumble out, and perhaps the queen among them; ſhe is often one of the laſt that falls: if ſhe is not there, ſearch for her among the main body in the empty hive, ſpreading them for this purpoſe upon a table. You muſt proceed in the ſame manner with the other hive, with the bees of which theſe are to be united.

One of the queens being found, you muſt put the bees of both hives together; mingle them thoroughly, ſprinkling them at the ſame time with a little ale and ſugar, and put them among the combs of the latter hive, ſhaking them down in it. When they are all depoſited, cover the hive with a cloth, bound cloſe about it, and let them remain ſhut up all that night and the next day. Some time after this you will be ſenſible that they are awakened out of ſleep. The ſecond night after their union, in the duſk of the evening, gently remove the cloth from the mouth of the hive (taking care of yourſelf), and the bees will immediately ſally forth with a great noiſe; but it being too late for them to take wing, they will ſoon return again: then inſerting two pieces of tobacco-pipes to let in air, ſtop them cloſe as before, and keep them thus confined for three or four days longer, after which the door may be left open.

The beſt time of the year for uniting them is when the young brood are all out, and before they begin to lodge in the empty cells, which they do in great numbers in cold weather and in winter. The operation ſhould be performed early in the afternoon, that, having the greater light, the queen may be more eaſily found. The few bees that are left in the hive ſhould be ſuffocated with ſulphur.

Mr. Thorley obſerves, that he never knew ſuch combined ſtocks conquered by robbers, and that they will either ſwarm the next ſummer, or yield a hive full of honey.

Mr. White's method of hiving a ſwarm into one or more of his boxes is as follows: take the looſe board, mentioned under the article Hive, and faſten it to one of the boxes, ſo as to ſtop the communication; this may be done by three of the ſtaples there mentioned, one on the top of the box near the front, the two others on the back near the top and near the bottom; let one end of the ſtaple be thruſt into a gimblet-hole made in the box, ſo that the other end may go as tight as poſſible over the looſe board, to keep it from ſlipping when it is handled. Be careful to faſten the ſhutter ſo cloſe to the glaſs that no light may enter through it; and cover the box as ſoon as the bees are hived, with a linen cloth thrown looſely over it, or with green boughs to protect it from the heat of the ſun. If the ſwarm be larger than uſual, inſtead of faſtening the looſe board to one box, you may join two boxes together with three ſtaples, leaving the communication open from one to the other, and then hive your bees in both. In all other reſpects they are to be hived in boxes after the ſame manner as in common hives. The door of the ſecond box ſhould be carefully ſtopped up and kept conſtantly cloſed, in order that the bees may have no entrance but through the firſt box.

In the ſwarming ſeaſons, ſays Mr. Iſaac, hives ſhould be in readineſs for the ſwarms. Three iron hooks ſhould be faſtened to as many cords, tied together at ſuch a diſtance from the hooks as to admit the hive between them, ſo that the hooks may be faſtened in the ſides of the hive at equal diſtances. The cords ſhould be looped above the knot, ſo that the hive may be ſupported by them on a forked ſtick, eight or ten feet long, and pointed at the lower end. When a ſwarm riſes, take ſome balm leaves and rub the inſide of the hive with them, and place them on the outſide under one of the cords; then by means of the long ſtick, wave the hive amongſt the bees as they float in the air, and thruſt the ſtick into the ground to ſupport the hive; then walk off, and uſe your tinkling bell till you ſee them beginning to enter, at which time the noiſe ſhould ceaſe. If they are not allured into the hive by theſe means, they will either pitch elſewhere or go off, in which caſe they ſhould be followed if poſſible. If they pitch on the ground, put the hive over them, and ſhade them with boughs of trees. If they ſettle on a buſh, hold the hive with one hand and ſhake the buſh with the other, juſt ſtrong enough to make them fall into the hive, and put it down on the ground acroſs a ſtick, with the entrance a little elevated towards the ſouth; but if they have fixed where this mode cannot be uſed, the manner of hiving will be more difficult and the ſucceſs leſs certain. Mr. Iſaac ſays, that he has ſometimes been obliged to tie ſeveral ſticks together to make a long crook, and to aſcend a ladder ſo as to hold the hive on the points of a long pitch-fork, while an aſſiſtant ſhook with the crook the branch of a high tree on which a ſwarm had fixed, and the bees ſeemed glad to be hived. If the bees ſeem uneaſy in the hive, the queen is not with them, or they are determined to go off. If they return to the ſtock they may ſwarm again ſoon; but if they go off and you can follow them, give the old ſtock another hive, and look about for the queen till they have ſettled, and avoid treading on any bees leſt you deſtroy the queen, or miſtake the bees. If you find her, place her at the entrance, and you will thereby ſecure the ſwarm. Thorley, White, and Iſaac, ubi ſupra. See Swarm.

HIWASSEE, in *Geography*, a river of America, which diſcharges itſelf into the Teneſſee, after paſſing through the Cherokee town, about 40 miles below the mouth of the Clinch. N. lat. 35° 38′. W. long. 85° 3′. It is navigable till it penetrates the mountains on its S. ſide. Theſe mountains, when poſſeſſed by the Britiſh, yielded ore, from which gold was extracted. A branch of the Hiwaſſee, called Amoia, almoſt interlocks a branch of the Mobile. The portage between them is ſhort, and the road firm and level.

HLINKA, a town of Bohemia, in the circle of Chrudim; 12 miles S. of Chrudim.

HLIWINO, a town of Lithuania, in the palatinate of Minſk; 44 miles E. of Minſk.

HLUBOKI, a town of Ruſſian Lithuania; 40 miles S.E. of Breſlaw.

HLUMCZA, a town of Poland, in the palatinate of Volhynia; 60 miles N.N.W. of Zytomiers.

HO, a town of China, in Se-tchuen. N. lat. 30° 8′. E. long. 105°.—Alſo, a city of the ſecond rank, in Chen-ſi. N. lat. 35° 48′. E. long. 102° 34′.—Alſo, a city of the ſecond rank, in Kiang-nan. N. lat. 31° 42′. E. long. 117° 54′.

HOA, a city of China, of the ſecond rank, in Quang-tong. N. lat. 21° 38′. E. long. 109° 49′.

HOACHE, in *Natural Hiſtory*, a name given by the Chineſe to a peculiar kind of earth, which they have found very uſeful in the manufacture of their China-ware. It is called hoache from the word *hoa*, which ſignifies *ſoft* and *glutinous*, and is deſcribed to us as being an earth approaching to the nature of chalk, but harder, and feeling like ſoap to the touch. There is great reaſon to believe, that this is either the ſame earth with our ſoap-rock of Cornwall, or ſomething very like it. But we are to learn, in regard to the Chineſe way of uſing it, that it is only one of the ingredients of their fine ware, not the whole matter of which it is made.

The Chineſe phyſicians had long uſed this earth as a medicine, giving it in diſorders of the lungs; but it is only of late times that the workmen in porcelain attempted to uſe it inſtead of kaolin. It ſucceeds, however, ſo well, that the porcelain made of it ſells dearer in the Indies than any other kind. The grain of this porcelain is remarkably fine and even, ſo that it is fitter for receiving the fineſt pencilling than any other, and it may be made ſurpriſingly light. But there is this diſadvantage, that the whole is more brittle than ordinary china, and the juſt degree of baking it is very difficult to hit; without which it is never ſtrong. The Chineſe ſometimes make the body of their veſſels of the common China-ware, and dip them when dry into a thick liquor like cream, in which the hoache is diſſolved; this gives a new and beautiful coat to the veſſel. They give the common varniſhing over this, and it ſucceeds to a very great perfection.

The manner in which the Chineſe uſe it for this purpoſe is this: they firſt waſh it clean with river water, to ſeparate a yellow ſort of earth, which lies near it in the mine where they dig it, and is often brought up with it. When it is thus cleaned, they beat it to powder, and mix in it large quantities of water; they ſtir the mixture well, and then letting the coarſer part ſettle, they pour off the thick liquor, and let it ſtand till a ſubſtance like cream ſubſides, which they keep moiſt, and uſe, as before mentioned, to dip the veſſels in, or elſe they dry it, and uſe it with the petunſe inſtead of the kaolin in the common manufactures.

It is ſaid that a good porcelain-ware may be made with this earth alone without any other mixture; but the workmen themſelves are unwilling to do this, and always chuſe, if they do not work in the common way, to add at leaſt two parts of the petunſe to eight of the hoache, and with this mixture they make a very good ware, working it in the ſame manner as they do the petunſe and kaolin.

The hoache, though ever ſo proper to ſupply the place of the kaolin, could not be uſed in the common works, becauſe it coſts three times the price, it being much ſcarcer, and brought much farther.

There is another very elegant ſort of China-ware, which depends entirely on the hoache for its beauty; it is all white, but though the ſurface is perfectly ſmooth and poliſhed, there are ſeen flowers and other ornaments on it in a very delicate manner. The method of making this is as follows: they make the veſſels of the common matter of the porcelain-ware; they then diſſolve, in a ſufficient quantity of clear water, as much of the refined hoache as will give it the conſiſtence of a ſyrup. With this they pencil out the figures they intend on the ſurface of the veſſel while not yet quite dry; this penetrates the ſurface, and the lines and ſtrokes all appear very determinate. They let this dry thoroughly, and then cover the whole veſſel with the common varniſh of the porcelain.

When it has been baked the whole appears white, but the figures are very diſtinctly ſeen, and appear extremely beautiful. They are of a brighter white than any of the reſt, and ſeem formed of a thin white vapour, running with regularity juſt under the ſurface of the veſſel. They have a way of doing this with another ſort of earth, which they call *chekao*; but this requires more trouble, as it muſt be roaſted and powdered before it is fit for uſe. The white of this alſo is not ſo fine when done as the other. Obſerv. ſur les Coutumes de l'Aſie, p. 300, &c. See Porcelain.

HOACTLI, in *Ornithology*, a ſpecies of *Ardea*. See Heron.

HOACTZIN. See Phasianus *Criſtatus*.

HOADLEY, Benjamin, in *Biography*, was born at Weſterham, in Kent, in the year 1676. He was educated in grammar learning under his father, who was a clergyman, and maſter of a private ſchool in his native place, and in the year 1691 he was entered a penſioner of Catharine Hall, Cambridge. Here, in due time, he took his degrees, and became a tutor in the college, the duties of which office he diſcharged with great reputation. As a divine he was firſt ſettled lecturer of St. Mildred, in the Poultry, London. Here he continued ten years; during this period he held other preferment in the church, which he obtained through Dr. Sherlock, dean of St. Paul's. In 1703 he publiſhed “The Reaſonableneſs of Conformity to the Church of England repreſented to the Diſſenting Miniſters, in anſwer to the tenth Chapter of Mr. Calamy's Abridgment of Mr. Baxter's Hiſtory of his Life and Times.” This was the occaſion of a controverſy between Mr. Hoadley and Mr. Calamy, which was carried on with that moderation which did credit to both parties. In 1705 Mr. Hoadley preached a ſermon before the lord mayor of London, which gave offence to the high-church party, and was followed by a long controverſy, in which many very eminent clergymen took a ſhare. After it had been continued a conſiderable time, the houſe of commons addreſſed the queen requeſting her to ſhew a regard for the ſignal ſervices which Mr. Hoadley had rendered to the cauſe of civil and religious liberty, by beſtowing upon him ſome dignity in the church. In anſwer to this addreſs the queen ſaid, that ſhe would take a proper opportunity of complying with their deſire, which, however, ſhe never did. Though neglected by his ſovereign he was not forgotten, but was preſented, in 1710, by Mrs. Howland, grandmother of the duke of Bedford, to the rectory of Streatham. Of this, he ſays, “When fury ſeemed to be let looſe, and to diſtinguiſh me particularly, ſhe herſelf, unaſked, unapplied to, without my having ever ſeen her, or been ſeen by her, choſe, by preſenting me to the rectory of Streatham, then juſt vacant, to ſhew, in her own expreſſion, that ſhe was neither aſhamed, nor afraid, to give me that public mark of her regard at that critical time.” Almoſt as ſoon as king George aſcended the throne Mr. Hoadley was nominated one of the chaplains to his majeſty, having been created doctor of divinity by archbiſhop Wake. This was a prelude to higher honours and a more elevated place in that church to which his learning and talents gave him a juſt title. In 1715 he was raiſed to the ſee of Bangor. In 1717 he preached before the king his celebrated ſermon on “The Nature of the Kingdom or Church of Chriſt,” which excited againſt him no little clamour among the clergy of the high-church party, and led to the controverſy which bears the biſhop's name. No ſooner had this ſermon been printed by ſpecial command, than it was deter-

-mined to proceed againſt the author in convocation, as ſoon as it ſhould ſit. The lower houſe drew up their repreſentation, but before it could be brought into the upper houſe, that aſſembly was prorogued by the king's order, nor was it permitted to ſit to do buſineſs till the heat of their reſentment had ſubſided. Dr. Hoadley's ſermon ſtruck at the root of civil and eccleſiaſtical tyranny: he ſhewed, in the moſt deciſive manner, that Chriſt was alone king in his own kingdom and the ſole law-giver; that his kingdom is not of this world, and that conſequently all encouragements and obſtacles of this world were not what Chriſt approved, tending to make men of one profeſſion, not of one faith; hypocrites not Chriſtians. Another very important tract publiſhed by Dr. Hoadley in this controverſy was entitled “The common Rights of Subjects defended, and the Nature of the Sacramental Teſt conſidered: in anſwer to Dr. Sherlock's Vindication of the Teſt and Corporation Acts.” The argument maintained in this piece is, that it is a proſtitution of the holy ſacrament to apply it to a purpoſe of a different nature from what the inſtitutor ſolemnly appropriated to it, and to make that the tool of this world, which he ordered to have reſpect only to another: and that the teſt and corporation acts are repugnant to reaſon and to juſtice. In 1720 Dr. Hoadley was tranſlated to the ſee of Hereford, and in 1723 he was raiſed to the much more valuable biſhopric of Saliſbury: ſtill he employed his pen in vindicating the cauſe of liberty, which was ever near his heart. In 1732 he drew up a memoir of Dr. Samuel Clarke, which was prefixed to the poſthumous works of that eminent divine. In the year 1734 he ſucceeded to the ſee of Wincheſter, and ſhortly after publiſhed a very uſeful treatiſe, entitled “A plain Account of the Nature and End of the Sacrament of the Lord's Supper, &c.” This work, which was intended to repreſent one of Chriſt's inſtitutions in its primitive ſimplicity, has been abridged by Dr. Diſney, and publiſhed under the title of “The national Chriſtian's Aſſiſtant to the worthy receiving of the Lord's Supper.” Dr. Hoadley attained to the advanced age of eighty-five, when he died at his palace at Chelſea. He had ever diſtinguiſhed himſelf by conſiderable learning and uncommon talents, which he conſecrated in the moſt honourable manner to the ſervice of mankind. He had at all times ſhewn himſelf ready to ſeize every opportunity to defend the cauſe of truth, virtue, and religion, and the principles of our excellent conſtitution, in whatever quarter attacked; and to aſſert and vindicate, on the moſt intereſting occaſions, and againſt the greateſt names, the rights of the throne and thoſe of Engliſhmen. An account of all the works of this great man may be found in the Supplement to the Biographia Britannica, to which the reader is referred.

Hoadley, Benjamin, M.D. eldeſt ſon of the biſhop of Wincheſter of that name, was born in Broad-ſtreet, on the 10th of February, 1705. He received his early education at the ſchool of Dr. Newcome at Hackney, and was admitted a penſioner of Bene't college, Cambridge, under the worthy archbiſhop Herring, who was at that time tutor. He determined to purſue medicine as a profeſſion; and he was diſtinguiſhed by the progreſs which he made in mathematical and philoſophical ſtudies, under the celebrated blind profeſſor Saunderſon. He was created M. D. in 1728 by royal mandamus, and ſettled in London as a phyſician. He was early received into the Royal Society; and was made regiſtrar of Hereford, while his father held that ſee. In 1737 he read the Gulſtonian lectures in the College of Phyſicians, which he publiſhed in 1740. It was very honourable to his character that he held, for ſome years, the appointment of phyſician to both the houſholds, being nominated to that of the king in June, 1742, and to that of the prince of Wales in January, 1745, at a time when the two families were not upon the beſt terms with each other. He died at his houſe at Chelſea, on the 10th Auguſt 1757, leaving no iſſue, although twice married. He left the following works: the lectures, above alluded to, under the title of “Three Letters on the Organs of Reſpiration, read at the College, &c. To which is added an Appendix containing Remarks on ſome experiments of Dr. Houlſton, publiſhed in the Tranſactions of the Royal Society for the year 1736;” 1740, 4to. This work is characterized by Haller, as a very ingenious defence of a bad cauſe. 2. An Harveian Oration, “Oratio Anniverſaria &c,” 1742, which has been eſteemed an elegant piece of Latinity. 3. “Obſervations on a Series of Electrical Experiments,” by himſelf in conjunction with Mr. Wilſon. 4. But Dr. Hoadley will be principally remembered as the author of the pleaſing comedy, “The Suſpicious Huſband,” written in 1747, which, by its own gaiety, and the admirable performance of Garrick, in the part of Ranger, became extremely popular, and it ſtill affords freſh pleaſure, whenever repreſented. He afterwards gave ſome aſſiſtance to his friend Hogarth, in the compoſition of his “Analyſis of Beauty.” Dr. Hoadley was a man of both elegant and ſolid accompliſhments, poſſeſſed of conſiderable learning in his profeſſion, and an agreeable and ſprightly companion. Hutchinſon Biog. Med. Gen. Biog.

HOAI-KING, in *Geography*, a city of China, of the firſt rank, in the province of Ho-nan, abounding with medicinal plants. N. lat. 35° 6′. E. long. 112° 34′.

HOAI-NGHAN, a city of China, of the firſt rank, in the province of Kiang-nan. It is ſituated in a marſh, and encloſed within a triple wall; the ground on which it ſtands being lower than the bed of the canal, the inhabitants live in a conſtant dread of inundation. The ſuburbs extend to the diſtance of a league on each ſide of the canal, and form at their extremity a kind of port on the river Hoang-ho. This place is very populous, and carries on an active and briſk trade. One of the great mandarins, who inſpect the canals, and ſupply the court with proviſions, reſides here. This city has two of the ſecond and nine of the third claſs, under its juriſdiction. N. lat. 53° 30′. E. long. 118° 47′.

HOAI-YU-KEOU, a town of Chineſe Tartary. N. lat. 40° 54′. E. long. 117° 22′.

HOANG, Hoan-ho, or *Yellow river*, ſo called from the yellow colour of the mould and ſand at its bottom and ſides, a river of China, which has its ſources in two lakes, among the mountains ſituated in that part of Tartary called Kokonor, about N. lat. 35°, E. long. 97°, and, after a very winding courſe of 2150 miles, through Tartary and China, diſcharges itſelf into the Eaſtern or Yellow ſea, N. lat. 34° 5′. E. long. 119° 44′. It is broad but ſhallow, ſo as to be hardly navigable; it is rapid in its courſe, and often overflows its banks, ſo that it has been found neceſſary to raiſe dykes in many places on its ſides, and even round many towns in the province of Ho-nan. At about ſeventy miles from the ſea, where it is croſſed by the Imperial canal, the breadth is little more than a mile, and the depth about nine or ten feet, but the velocity is about ſeven or eight miles in the hour. Yu, ſurnamed the *Great*, directed its courſe acroſs the provinces of Chan-ſi, Chen-ſi, Ho-nan, and Pe-tcheli; and towards its mouth, in order to check its rapidity, he divided it into nine channels, by which it diſcharged itſelf into the ſea, near the mountain of Kia-che-chan, which then formed a promontory. Since Yu, to the preſent time, *i. e.* in the interval of about 3950 years, the river Hoang-ho has departed ſo much from its ancient courſe, that its mouth is at preſent ſix degrees farther ſouth. It flowed into the ſea formerly under the fortieth degree of N. lat. ; at preſent nearly under the thirty-fourth. Beſides, the mountain Kia-che-chan, which was formerly united to the main land of Yong-ping-fou, ſtands at preſent in the ſea, at the diſtance of 50 leagues to the S. of that city.

HOANG-TCHEOU, a city of China, of the firſt rank, in the province of Hou-quang, ſituated on the Yang-tſe, and having under its juriſdiction one city of the ſecond rank, and eight cities of the third. N. lat. 38° 28′. E. long. 114° 26′.—Alſo, a town of Corea, in Hoan-hi, 85 miles N.W. of King-ki-tao. N. lat. 38° 42′. E. long. 125° 52′.

HOAPINSU, a ſmall iſland in the Chineſe ſea, belonging to the group called "Lieou-Kieou." N. lat. 25° 44′. E. long. 123° 34′.

HOAR FROST, *Pruina*. See FROST.

HOARE, WILLIAM, in *Biography*, was born in the year 1707, of reſpectable parents, at Eye in Suffolk, and received the advantages of education in a ſchool, at that time of high repute for claſſical inſtruction. He diſcovered an early diſpoſition for painting, and gave ſuch inconteſtible proofs of a natural talent for that art, at an annual prize exhibition, that, after his completion of the uſual ſtudies of the ſchool, his father carried him to London, and placed him under the tuition of Griſoni, an Italian painter. From the ſkill of Griſoni the ſcholar could derive little profit; but it is probable, that from his converſation he imbibed that ardent deſire of viſiting the works of the Italian maſters, which prompted him to ſet the example of a ſyſtem afterwards purſued with ſo much avidity and ſucceſs by moſt of our young ſtudents in painting. The name of William Hoare ſtands firſt on the liſt of thoſe Engliſh painters who have reſorted to Italy with a view to profeſſional improvement.

Arriving at Rome, he placed himſelf in the ſchool of Franciſco Imperiali, and was the fellow pupil of Pompeo Battoni. During a reſidence of nine years in Italy, he made numerous copies of the hiſtorical works of the great maſters, and he returned to England, filled with viſionary hopes, and an ardent love of his profeſſion, which did not deſert him even at the lateſt period of an extended life.

Finding himſelf a ſtranger in London, and without the means of rendering his talents known, he accepted an invitation from ſome of his friends who reſided at Bath, in Somerſetſhire, and there found ſuch conſtant employment in painting portraits, that he was induced to ſettle in that city.

From the ſtudy of Roſalba's pictures, he added the practice of crayons to that of oil-painting, and carried it to a degree of excellence ſecond only to the powers of that celebrated paintreſs.

He maintained at Bath a very high character as a portrait painter, and he enjoyed ſcarcely leſs reputation for taſte and literature; and, as to theſe attractive qualities, he added the moſt unblemiſhed integrity, his houſe became the continual reſort of men of rank and genius. In the courſe of fifty years of profeſſional attention, he pourtrayed moſt of the diſtinguiſhed characters of the age.

Amidſt this eaſy affluence, he employed the earlieſt moments of his leiſure in the indulgence of his favourite wiſh of higher achievement in his art. He gave to the altar of St. Michael's church, at Bath, a figure of Our Saviour, as large as, or larger than, life; and afterwards painted for the octagon chapel, in that city, an hiſtorical compoſition, repreſenting, "The Miracle at the Pool of Betheſda."

Theſe exertions procured him commiſſions for a few hiſtorical pictures, the principal merit of which conſiſts in the diſplay of an elegant taſte, and faithful ſtudy of nature.

Reſiding at a diſtance from the metropolis, where the competition of younger artiſts was continually accelerating the advance of Engliſh art, he retained to the laſt the ſtyle which he had adopted in the Italian ſchool. His drawing was more correct than that of moſt of his contemporaries; but his works are deficient in the richneſs of colour and effect, which began generally, in his time, to prevail in the ſchool of this country, and by which it is now ſo eminently diſtinguiſhed.

His portraits of men were faithful reſemblances of their originals, but they are ſeldom ſufficiently diveſted of the formal air which was long thought requiſite to the decorum of portraits. His portraits of women, particularly in crayons, have frequently much grace and ſoftneſs; his moſt celebrated portrait in oil is a half-length of William Pitt, the firſt earl of Chatham.

On the formation of the Royal Academy he was elected one of the original members, and was a conſtant exhibitor for many years. He died at Bath in 1792.

HOARSENESS, in *Medicine*, *raucedo*, an alteration in the voice, which gives it a preternatural roughneſs and diſſonance, and generally a lower or graver tone. The word is ſometimes alſo applied, though incorrectly, to a diminution or loſs of the voice. It is called by Sauvages Paraphonia catarrhalis. Noſol. Method. Claſs VI. Gen. 16.

The ancient phyſicians agree in referring hoarſeneſs to a roughneſs in the internal ſurface of the trachæa or windpipe; and the moderns, before the time of Sauvages, attributed that ſuppoſed roughneſs to the enlargement of miliary glands in the part, conſequent upon the action of cold, in the ſame manner as the cutis anſerina, or gooſe-ſkin appearance, is produced in the ſkin by the ſame agent. But that noſologiſt remarks, that if a German flute be wetted within, and afterwards ſand thrown into it ſo as to roughen the internal ſurface of the tube, the tone is not rendered either flat or rough, as thoſe phyſiologiſts ſuppoſe. It cannot be doubted, indeed, from what we know of the effects of inflammation in membranous parts, that this alteration of the voice ariſes from the thickened condition of the membrane lining the larynx, by which the diameter is altered and rendered irregular, and which, extending alſo to the muſcles of vocality, prevents them from contracting the aperture regularly or ſufficiently. In other caſes, where there is both a diminution of the power of voice, and a hoarſe tone, and theſe of conſiderable duration, the affection originates probably from ulceration and partial loſs of ſubſtance about the larynx or glottis. In ſome inſtances, a loſs of the voice ſeems to be dependent upon a degree of paralyſis in the muſcles of the larynx, by which they are diſabled from opening and cloſing that paſſage. This variety of the diſorder ſometimes continues for months, or even years; and the voice generally returns very ſuddenly, even ſo as to alarm the patient. (Darwin's Zoonomia, Claſs III. 2. 1. 5.) A temporary hoarſeneſs ariſes often from ſhouting or long and loud talking, by which a tranſient degree of inflammation appears to be produced in the larynx, and is accompanied by a ſenſation of ſoreneſs in the throat.

The hoarſeneſs, accompanying a common catarrh, is, of courſe, the effect of expoſure to cold; that which is occaſioned by ulceration in the organs of the voice is commonly occaſioned by the ſyphilitic virus, or ſome other chronic affection, to which the term ſcrofulous is ſometimes applied.

The cure of hoarſeneſs will neceſſarily be various according-to the nature and origin of it; and as it is commonly only ſymptomatic of ſome other diſeaſe, will conſiſt in removing that primary affection. When it is connected with a common cold and cough, or ſore throat, it will ceaſe with the inflammation accompanying them; but it may be much relieved by inſpiring the ſteam of water alone, or of water and vinegar, or of water and ether. Bliſters to the external fauces often relieve the catarrhal hoarſeneſs, and ſometimes alſo the paralytic hoarſeneſs. In the latter variety, and in the hoarſeneſs attendant on chronic coughs in old and feeble people, as well as in ſome chronic ulcerations of the mouth and throat, certain warm and ſtimulant gargles and linctuſes have been uſed with advantage. In ſuch caſes Dr. Cullen recommended the juice of the hedge-muſtard (Eryſimum officinale) mixed with an equal quantity of honey or ſugar. When the eryſimum was not at hand, Dr. Cullen ſubſtituted a ſyrup of horſe-radiſh (cochlearia armoracia.) "I have found one drachm of the root," he obſerves, "freſh ſcraped down, was enough for four ounces of water, to be infuſed in a cloſe veſſel for two hours, and made into a ſyrup with double its weight of ſugar. A tea-ſpoonful or two of this ſyrup, ſwallowed leiſurely, or at leaſt repeated two or three times, we have found often very ſucceſsful in relieving hoarſeneſs." Cullen Mat. Med.

In the complete loſs of voice, Dr. Darwin recommends electric ſhocks to be paſſed through the larynx, by which two young ladies were cured in a fortnight. He likewiſe ſuggeſts the adminiſtration of emetics, gargles of decoction of ſeneka, and frequent endeavours to ſhout and ſing,—friction externally, and ſea bathing.

HOASE, in *Sea Language*, is a long flexible tube, formed of leather or tarred canvas, but chiefly of the latter, and employed to conduct the freſh water, which is hoiſted aboard a ſhip, into the caſks that are ranged in the hold; and to paſs the water, or other liquors, out of one caſk into the other.

HOATCHIT, in *Geography*, a country of Chineſe Tartary, governed by a Mongul prince, tributary to the empire, formed into two ſtandards; ſituated to the N. of Peking. N. lat. 45°.

HOATH. See HOWTH.

HOA-TSIANG, a town of Thibet; 30 miles E.S.E. of Hami. N. lat. 40° 55′. E. long. 99° 19′.

HOBAL, in *Mythology*, an idol of the ancient Arabs, the worſhip of which at Mecca was deſtroyed by Mahomet.

HO-BASCH, in *Geography*, a town of Arabia, in the province of Yemen; 44 miles E. of Zebid. N. lat. 4° 18′. E. long. 44°.

HOBBIES KEYS, a ſmall cluſter of iſlets, and rocks, in the Spaniſh Main, near the Moſquito ſhore. N. lat. 12° 18′. W. long. 82° 50′.

HOBBIMA, MINDERHOUT, in *Biography*, a moſt excellent landſcape painter, born at Antwerp about the year 1611. It is not exactly known under whom he learnt the principles of his art; but that nature was his ultimate guide to the perfection he attained, is very evident in his pictures, than which none were ever painted more true.

His choice of ſubjects, for they generally appear to have been portraits of particular places, is exceedingly pictureſque, though of a low and common kind. The border of a wood with a few ſcattered huts and fields viſible through the trees; a narrow lane with a cottage and hedge-rows; a corn-field, and village at a ſhort diſtance, in his hands, became intereſting, from the ſkill with which he arranged the chiaro-ſcuro and colouring, and the brilliancy and freedom of touch whereby he gave the full character of each object, and its local place in the perſpective of the picture. The forms of his trees are purely imitated from nature, without any apparent attempts to idealize them, to give them a more compact maſs in their extreme parts, as Claude, with a more exalted taſte, has effected. Hobbima appears to have taken nature as he found her, and been contented with repreſenting her truly; and he has certainly acquired the firſt name amongſt thoſe who have taken this line of ſtudy, which his own countrymen have generally done. Ruyſdael had better ſelections than he, but was not ſo rich in colour, nor ſo powerful in effect. Many of his pictures are ſupplied with figures by Oſtade, A. Vandevelde, and other ſkilful maſters, which gives them additional value; and they are now very highly valued and eagerly ſought after.

HOBBISM, or *Philoſophy of Hobbes*, in the *Hiſtory of Literature*, denotes the metaphyſical, moral, religious, and political opinions of Thomas Hobbes, a celebrated Engliſh writer, who was born at Malmeſbury, in Wiltſhire, in the year 1588.

Having diſtinguiſhed himſelf in early life by his genius, application, and improvement, he was taken into the ſervice and protection of the Devonſhire family, which continued, with little interruption, as long as he lived, and which gave him an opportunity of purſuing his ſtudies, and of forming connections with perſons of the firſt reputation for learning and ſcience both at home and abroad.

His firſt work was an Engliſh tranſlation of the "Hiſtory of Thucydides," which he publiſhed with a view to the ſtate of his country, in order to ſhew the fatal conſequences of inteſtine broils.

Having acquired a thorough aquaintance with the Latin and Greek languages, he applied himſelf to the ſtudy of mathematics; and particularly to the works of Euclid, which he read and admired, principally on account of the clearneſs of his reaſoning, the connection of his arguments, and the wonderful perſpicuity of his method. He alſo devoted his leiſure hours to natural philoſophy, and eſpecially to mechanics and the cauſes of animal motion.

In 1640 he retired to Paris, where he became acquainted with the famous Des Cartes, with whom he afterwards correſponded, and whoſe doctrine concerning innate ideas he ſtrenuouſly oppoſed.

In 1642 he printed a few copies of his book "De Cive," a more complete edition of which was printed in Holland in 1647, by the care of Dr. Sorbiere. To this edition two recommendatory letters are prefixed; one written by Gaſſendi and the other by Merſenne, with whom Mr. Hobbes was on terms of intimate friendſhip.

In 1650, two other treatiſes were publiſhed at London; one entitled "Human Nature," and another entitled "De Corpore Politico," or the Elements of Law. During this time he had been digeſting his religious, political, and moral principles, into a complete ſyſtem, which he entitled "Leviathan;" and which was printed in Engliſh, at London, in that and the following year. Soon after this publication he returned to England, and joined in communion with a congregation where the ſervice of the church of England was uſed, and continued to reſort thither.

In 1654 he publiſhed his letter upon "Liberty and Neceſſity," which occaſioned a long controverſy between him and Dr. Bramhall, afterward lord primate of Ireland. About this time he likewiſe began a controverſy with Dr. Wallis of Oxford, which laſted as long as he lived, and in which he had the misfortune to have all the mathematicians againſt him. This controverſy did him no credit; for though he was once and again refuted, and his miſtakes were clearly pointed out, yet, ſuch was the obſtinacy of his temper, he adhered as pertinaciouſly as ever to his old opinions, and rendered that a perſonal quarrel, which ought to have continued a literary diſpute. He was no leſs poſitive and imperious in maintaining his moral, religious, and political ſentiments; and he ſeems to have diſcovered, on a variety of occaſions, a very unbecoming opinion of his own abilities, and a ſupercilious contempt for thoſe of other men.

After the reſtoration, in 1660, the king ſettled upon him a penſion of a hundred pounds a year; but notwithſtanding this favour, his Leviathan and his treatiſe De Cive were cenſured by parliament in 1666, a circumſtance which much alarmed him. At the ſame time a bill was brought into the houſe of commons to puniſh atheiſm and profaneneſs, which, it is ſaid, induced Mr. Hobbes to write or enlarge his book concerning Hereſy.

In 1675, he publiſhed his Engliſh edition of the Iliad and Odyſſey; in 1676 his diſpute with Dr. Laney, biſhop of Ely, concerning Liberty and Neceſſity, was printed; in 1678, appeared his "Decameron Phyſiologicum," or ten Dialogues of Natural Philoſophy; and about the ſame time a new edition of the "Art of Rhetoric," to which he added a Dialogue between a Philoſopher and a Student of the Common Law of England; in the ſame year he alſo publiſhed his "Behemoth," or Hiſtory of the Civil Wars from 1640 to 1660.

Mr. Hobbes retained his underſtanding to his laſt ſickneſs; inſomuch that he was not only capable of ſtudying mathematics when above eighty-ſix years old, but alſo of writing very long poems. It has been ſaid, that he was afraid of apparitions and ſpirits; but his friends call this a fable, though they acknowledge that he was afraid of being alone, and aſcribe it to a fear of being aſſaſſinated. Mr. Bayle obſerves, that he meditated much more than he had read, and that he never cared to collect a large library; and Mr. Hobbes ſays of himſelf, that if he had beſtowed as much time on reading as other men of letters, he ſhould have been as ignorant as they. He was a great admirer of Homer, Virgil, Thucydides, and Euclid; but he made no account of large libraries, obſerving that men, for the moſt part, following one another's ſteps like ſheep, have ſeldom the courage to go out of the trodden paths and roads which are preſcribed to them by their guides. Mr. Hobbes died at the houſe of his patron, the earl of Devonſhire, in the year 1679. For a fuller account of his life and writings, the reader may conſult Bayle, or the Biographia Britannica, article *Hobbes*.

Mr. Hobbes's religious and political ſentiments are chiefly contained in his book De Cive and his Leviathan; and it is certain, that there have been few perſons whoſe writings, by the extraordinary abilities of their author and the ſingularity of his notions, for the dogmatical manner in which they are delivered, and the agreeableneſs of their ſtyle, that have had a more pernicious influence in ſpreading infidelity and irreligion, though none of them are directly levelled againſt revealed religion.

Mr. Hobbes has been unjuſtly charged with atheiſm; for he expreſsly acknowledges the exiſtence of God, and that we muſt neceſſarily ariſe from the effects which we behold, to the eternal power of all powers, and cauſe of all cauſes; and he blames the abſurdity of thoſe, who call the world, or the ſoul of the world, God: nevertheleſs, he denies that we know any more of him than that he exiſts, and ſeems plainly to make him corporeal; for he affirms, that that which is not body is nothing at all: "Dantur nomina inſignificantia; hujus generis eſt ſubſtantia incorporea." Religion, he ſays, ariſes from the fear of power inviſible, feigned by the mind, or imagined from tales publicly allowed, as ſuperſtition ariſes from thoſe that are not allowed; and he elſewhere reſolves religion into opinions of ghoſts, ignorance of ſecond cauſes, devotion to what men fear, and taking things caſual for prognoſtics. He takes pains in many of his works to prove man to be a neceſſary agent (if theſe contradictory terms can be properly joined), and expreſsly aſſerts the materiality and mortality of the human ſoul; alleging, againſt the well-known maxim of Des Cartes, "I think, therefore, I am," another maxim of his own, "I think, therefore, matter can think." And he repreſents the doctrine concerning the diſtinction between ſoul and body in man to be an error, contracted by the contagion of the demonology of the Greeks. The belief of a future ſtate, he ſays, is grounded upon other men's ſaying that they knew it ſupernaturally, or that they knew thoſe that knew them, that knew others, that knew it ſupernaturally.

With regard to revealed religion, he treats the pretence to inſpiration as a ſign of madneſs; he alleges that the books of Moſes, and the hiſtorical writings of the Old Teſtament, were not written by thoſe whoſe names they bear; and that they are derived to us from no higher authority than that of Ezra. As to the books of the New Teſtament, he acknowledges, that they are the true regiſters of thoſe things which were done and ſaid by the prophets and apoſtles; but he pretends, that they were not received as of divine authority in the Chriſtian church, till they were eſtabliſhed by the council of Laodicea, in the year of Chriſt 364. Though he ſometimes ſeems to ſpeak with veneration of the ſacred writings, and to make the laws of ſcripture the laws of God, yet he expreſsly aſſerts, that we have no aſſurance of the certainty of ſcripture but the authority of the church, or the authority of the commonwealth; that the precepts of ſcripture derive all their obligation from the will of the magiſtrate; and that the magiſtrate is the authoritative interpreter of all ſcripture doctrines, to whom we are bound to ſubmit. On the ſame principle he maintains, that the private reaſon muſt ſubmit to the public, *viz.* to God's lieutenant; that a ſubject may be allowed to deny Chriſt in words, provided he retains the faith of Chriſt in his heart, when commanded by his ſovereign; and that idolatry, to which a man is compelled by the terror of death, is no idolatry.

Mr. Hobbes's opinions with regard to natural religion and civil government are equally erroneous and extravagant; he aſſerts, that by the law of nature every man has a right to all things, and over all perſons, and that the natural condition of man is a ſtate of war, a war of all men againſt all men; that every man acts reaſonably, who endeavours, as far as poſſible, to maſter all the perſons of others, till he ſees no other power great enough to endanger him; that the civil laws are the only rules of good and evil, juſt and unjuſt, honeſt and diſhoneſt, and that antecedently to ſuch laws every action is in its own nature indifferent; that there is nothing good or evil in itſelf, nor any common laws conſtituting what is naturally juſt or unjuſt; that all things are eſtimated by what every man judgeth to be fit, where there is no civil government, and by the laws of ſociety, where ſociety is eſtabliſhed; that the power of the ſovereign is abſolute, and that he is not bound by any compact with his ſubjects; that nothing the ſovereign can do to the ſubject can properly be called injurious or wrong; and that the king's word is ſufficient to take any thing from any ſubject, if there be need, and the king is judge of that need. "Non veritas, ſed auctoritas facit legem." And yet he elſewhere ſays, "Obligatio civium erga eum qui ſummam habet poteſtatem tandem nec diutius permanere intelligitur, quam manet potentia cives protegendi."

Wood, in his Athenæ Oxon. vol. ii. p. 646, has aſſerted, that Mr. Hobbes, in advanced life, retracted many of his opinions publiſhed in his Leviathan, &c. and compoſed an apology for himſelf and his writings; but the authenticity of this apology has been diſputed. Leland's View of the Deiſtical Writers, vol. i. letter iii. Moſheim's Eccl. Hiſt. by Dr. Maclaine, vol. v.

HOBBY was a name formerly given to ſtrong active horſes of a ſmaller ſize; they are reported to have been originally natives of Ireland, and were much liked and uſed. Nags anſwer the ſame deſcription as to ſize, qualities, and employments.

HOBBY, in *Ornithology*, the Engliſh name of a hawk of the long-winged kind; the falco ſubbuteo of Linnæus, called by many authors, by the name *ſubbuteo*, the name by which others expreſs the ring-tail and hen-harrier. See FALCO.

HOBBYHORSE-HEAD, in *Mining*, ſignifies part of the pulley geer of a coal gin, fixed over the drawing-ſhaft.

HOBGOBLIN is a name vulgarly applied to fairies or apparitions. Skinner calls the word *robgoblins*, and derives it from *Robin Goodfellow*, Hob being the nick-name of Robin; but Wallis and Junius, with greater probability, derive it from *hopgoblins*, *empuſæ*, becauſe they are ſuppoſed to *hop* without moving both their feet. Johnſon.

HOBITS, in *Gunnery*. See HOWITZER.

HOBLERS, or HOBILERS, HOBELARII, in our *Ancient Cuſtoms*, were men who, by their tenure, were obliged to maintain a light horſe or hobby, (whence their name,) for the certifying any invaſion towards the ſea-ſide.

The name was alſo uſed for certain Iriſh knights, who uſed to ſerve as light-horſemen upon hobbies. (18 Ed. III. ſtat. 1. c. 25, and ſtat. 5, c. 8.) The term, according to Spelman, continued till the time of Henry VIII. or that of queen Mary; when theſe troops were diſtinguiſhed by the name of demilaunces and light horſe. They are mentioned as part of the Britiſh army that attended king Edward II. into Scotland in the year 1322. Sometimes archers were mounted on light horſes; and they were hence ſtyled hobiler archers.

HOB-NAIL, a nail with a thick ſtrong head, uſed in ſhoeing a hobby or little horſe. Johnſon.

HOB-NOB, or HAB-NAB, a cant word formed from *hap ne hap*, and denoting an event which happens at random or by mere chance. Johnſon.

HOBOO, a name given by the people of Otaheite, and in the neighbouring iſlands of the South Sea, to their ſuperfine cloth. It is the thinneſt and moſt finiſhed preparation of the *aouta*, which ſee.

HOBRECHT, JACOB, in *Biography*, or as the Italians write it, *Obrecht*, or *Obreth*, the moſt ancient compoſer of maſſes, in correct counter-point of four parts, that are come down to us. He was a Netherlander, and the muſical preceptor of Eraſmus, as Damon was formerly of Socrates. Glareanus, the diſciple of Eraſmus, ſays, that he had frequently heard his preceptor ſpeak of Hobrecht as a muſician who had no ſuperior, and ſay, that he had ſuch a rapid and wonderful facility in writing, that he compoſed an excellent maſs in one night, which was very much admired by the learned. Indeed, in ſcoring his maſs "Si Dedero," which was printed at Venice in 1508, it appears, though the movements are ſomewhat too ſimilar in ſubject, that the counterpoint is clean, clear, and maſterly. And this is the chief praiſe that is juſtly due to moſt of the compoſitions of the ſame period; which, in other reſpects, ſo much reſemble each other, that a few ſpecimens would exhibit almoſt all the variety of melody and meaſure which the productions of a whole century can furniſh. Indeed, as air and grace were not at this time the objects of a compoſer's purſuits, they ſhould not be ſought or expected. Thoſe, however, who have heard modern melody, harmony, and modulation, to a degree of ſatiety, and admire the fugues, canons, and other ingenious contrivances of the ſixteenth and ſeventeenth centuries, would have great pleaſure in the performance or contemplation of ſuch muſic as this, which is become *new* by exceſs of antiquity. Few or none of the paſſages have been retained in modern muſic; and the harmony and modulation having been regulated by the eccleſiaſtical tones, or modes, which have been ſo long exploded in this country, every thing would be as new to a *dilettante* of the preſent age, as if he only now heard muſic for the firſt time; ſo that, thoſe who can tolerate nothing but what is *ancient*, and thoſe, who are in conſtant ſearch of *ſomething new*, will, in theſe authors, find muſic equally adapted to their ſeveral taſtes, and be likewiſe furniſhed with an excuſe for their faſtidiouſneſs.

HOBROE, in *Geography*, a town of Denmark, in North Jutland, and dioceſe of Wiborg; 16 miles N.E. of Wiborg. N. lat. 56° 38′. E. long. 9° 49′.

HOBSON's-CHOICE, a vulgar proverbial expreſſion, applied to that kind of choice in which there is no alternative. It is ſaid to be derived from the name of a carrier at Cambridge, who let out hackney horſes, and obliged each cuſtomer to take in his turn, that horſe which ſtood next the ſtable door. Scott.

HOBY, in *Geography*, a town of Sweden, in Sudermania; 15 miles N.W. of Nikioping.

HOCHAUS, a town of Auſtria; nine miles S.S.W. of Aigen.

HOCHBERG, a marquiſate of Germany, annexed to the margraviate of Baden, deriving its name from an ancient caſtle, ſituated two miles N.E. from Emendingen, which is the principal town.

HOCHENAU, a town of Auſtria; nine miles E.N.E. of Ziſterſdorff.

HOCHFELDEN, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the diſtrict of Saverne; 12 miles N.W. of Straſburg. The place contains 1620, and the canton 11,954 inhabitants, on a territory of 150 kiliometres, in 30 communes.

HOCHLAND, HOGLAND, or *Highland*, an iſlet or rock in the the middle of the gulf of Finland, of an oblong form, about 8 miles in circumference, having upon it two lighthouſes, and about 30 families of Finns. In the heart of the iſle is a deep and gloomy vale about 100 fathoms wide. The ſoil of this iſland is generally ſwampy; but it is not deſtitute of wood, ſuch as pines, firs, birch, alder, &c. On the higheſt rocks are three lakes, which are not without fiſh. Of domeſtic animals here are a few cattle and a flock or two of ſheep. Of wild fowl there are various ſpecies. Seals abound and herrings are plentiful. N. lat. 60° 3′. E. long. 27°.

HOCHST, a town of Germany, ſituated on the Maine; 6 miles W. of Francfort.

HOCHSTADT, a town of Bohemia, in the circle of Boleſlau; 11 miles from Turnau.

HOCHSTATT, or HOCHSTETT, a town of Bavaria, in the principality of Neuberg, on the Danube. Near this place was fought the famous battle of Blenheim (ſee BLENHEIM); 19 miles N.W. of Augſburg.

HOCHSTETT, a town of the biſhopric of Bamberg, on the Aiſch; 13 miles S. of Bamberg. N. lat. 49° 46′. E. long. 10° 47′.

HOCHWEISH, a town of Hungary; 20 miles W.S.W. of Kremnitz.

HOCK. See HAM.

Hock-*Tueſday money.* See Hoke-*day*.

HOCKHEIM, in *Geography*, a town of Germany, ſituated near the conflux of the Rhine and Maine; celebrated for its excellent wine; 16 miles N. of Francfort on the Maine.

HOCKHOCKING, a river of America, in the ſtate of Ohio, about 25 miles below the Muſkingum, which it reſembles, though inferior to it in ſize. It riſes near a branch of the Scioto, and purſuing a S. W. courſe enters the Ohio, at Bellpré, in N. lat. 38° 57′. It is navigable for large flat-bottomed boats, between 70 and 80 miles; and on its banks are fine meadows, ſeldom overflowed, and on its borders are rich upland. Its banks ſupply inexhauſtible ſources of free-ſtone, iron-ore, lead, and coal. Here are alſo productive ſalt-ſprings, with beds of white and blue clay of excellent quality. Red bole, and many other uſeful foſſils, have been found on its banks.—Alſo, a poſt-town in Roſs county, Ohio; 440 miles from Waſhington.

HOCKQUAR, or Hockquart, an iſland of Upper Canada, on the E. ſide of lake Superior.

HOCKSENBERG, a town of Pruſſia, in Pomerelia; 30 miles W. of Dantzic.

HOCKSTETT, a town of the biſhopric of Bamberg; 12 miles S. of Bamberg.

HOCUB, in *Botany*, a name given by Vaillant to a genus of plants, called by Tournefort and other authors gundelia.

HOCUS POCUS, a cant term applied to a juggle or cheat. Dr. Tillotſon derives it from the form of conſecrating the ſacramental bread in the Romiſh church, *hoc eſt corpus*. Junius derives it from the Welch *hocced, a cheat*, and *poke*, or *pocus, a bag;* the jugglers uſing a bag for conveyance. The etymology, however, is uncertain. Johnſon.

HOD, a ſort of tray for carrying mortar, in uſe among bricklayers.

HODAL, in *Geography*, a ſea-port town of Sweden, in Weſt Gothland, on the coaſt of the North ſea; 45 miles N. N.W. of Uddevalla.

HODAM, a town of Scotland, in the county of Dumfries; 10 miles E. of Dumfries.

HODDESDON, a market-town and chapelry in the pariſhes of Amwell and Broxbourn, in the hundred and county of Hertford, England, is ſituated near the river Lea; 17 miles diſtant from London. It conſiſts principally of one ſtreet, and, in the year 1801, contained 227 houſes, and 1227 inhabitants. The privileges of a weekly market, held on Tueſdays, and a three days annual fair, were granted by Henry VIII. The original market-houſe, a curious edifice of wood, ſupported on arches, is yet ſtanding, and is decorated with a number of rude and groteſque figures, carved on different parts. The chapel, a neat brick building, was erected about the year 1786, on the ſcite of an ancient ſtructure. Near the market-houſe is a conduit of good water, which is ſupplied by pipes from a ſpring at ſome diſtance; it was built by the Rawdons, a reſpectable family in this town; and is kept in order purſuant to the will of Marmaduke Rawdon, eſq. who, in 1679, bequeathed an annual proviſion for that purpoſe. The town is poſſeſſed of an incorporated grammar-ſchool; and in the vicinity is a large cotton-mill. Near the ſouthern extremity of the town is a large houſe, which preſents, both externally and internally, various ſpecimens of curious architecture, ſculpture, and carving. See Chauncy's "Hiſtory, &c. of Hertfordſhire," and Lyſons's "Environs of London," 4to. 1811.

HODEGOS, a term purely Greek, ὁδηγὸς, ſignifying *guide*. The word is chiefly uſed as the title of a book compoſed by Anaſtaſius the Sinate, toward the cloſe of the fifth century; being a method of diſputing againſt the heretics, particularly the Acephali.

Mr. Toland has alſo publiſhed a diſſertation under the ſame title. Its ſubject is the pillar of fire, &c., which went before the Iſraelites as a guide in the deſert.

HODEIDA, in *Geography*, a ſea-port town of Arabia, on the Red ſea, with a harbour fit only for ſmall veſſels. The juriſdiction of the Dola, who is accountable only to the Imam, is confined to this city. His revenue conſiſts in part of the duties upon coffee exported. The manſion-houſe of the Dola, the cuſtom-houſe, and the houſes of the principal merchants, are conſtructed of ſtone; the reſt of the town is compoſed of huts built in the ordinary ſtile. Near the ſea ſtands a ſmall citadel, incapable of affording a very ſtrong defence. This city has its patron ſaint Scheick "Sadik," who is honoured with due veneration. At the diſtance of 1½ mile from Hodeida is a well of excellent water, which ſupplies the inhabitants.

HODEN, a town of Africa, in the Sahara. N. lat. 19° 25′. W. long. 12°.

HODENSTEIN, in *Natural Hiſtory*. See Enorchis.

HODGE-PODGE. See Hotch-pot.

HODGES, Nathaniel, in *Biography*, a phyſician, the ſon of Dr. Thomas Hodges, dean of Hereford, was born at Kenſington. He was educated at Weſtminſter ſchool, and was elected a ſtudent of Chriſt-church, Oxford, in 1648. He obtained the degree of M. D. in 1659, and ſettled in practice in London. He remained in the metropolis during the continuance of the plague in 1665, when moſt of the phyſicians, and Sydenham among the reſt, retired to the country: and, with another of his brethren, he viſited the infected during the whole of that terrible viſitation. Theſe two phyſicians, indeed, appear to have been appointed by the city of London to attend the diſeaſed, with a ſtipend. Dr. Hodges was twice taken ill during the prevalence of the diſeaſe; but by the aid of timely remedies he recovered. His mode of performing his perilous duty was this: he received early every morning, at his own houſe, the perſons who came to give reports of the ſick, and convaleſcents, for advice; he then made his forenoon viſits to the infected, cauſing a pan of coals to be carried before him with perfumes, and chewing troches while he was in the ſick chamber. He repeated his viſits in the afternoon. His chief prophylactic was a liberal uſe of Spaniſh wine, and cheerful ſociety after the buſineſs of the day. Having thus had ample opportunities of aſcertaining the phenomena of the diſeaſe, he publiſhed, in the year 1672, a work under the title of "Loimologia; ſive Peſtis Nuperæ apud Populum Londinenſem graſſantis Narratio Hiſtorica," 8vo.; which contains the moſt authentic account of that memorable calamity. He ſubjoined the bills of mortality of the plague-year, 1665, amounting in all to 97,306 deaths, of which 68,596 were occaſioned by the peſtilence. This volume was tranſlated into Engliſh by Dr. Quincy, and publiſhed, with ſome additional tracts upon the ſubject, in 1721, when the occurrence of the plague at Marſeilles excited conſiderable alarm in the commercial cities throughout Europe. It is to be lamented, that a man, who had performed thoſe dangerous duties among his fellow-citizens with ſo much intrepidity and fidelity, ſhould have ultimately been ſo far reduced in his circumſtances, as to be confined in the priſon of Ludgate for debt, where he died in 1684. His body was interred in the church of St. Stephen, Walbrook, where a monument is erected to his memory. The only other work publiſhed by Dr. Hodges, was entitled "Vindiciæ Medicinæ et Medicorum," and printed in 1660, 8vo. See Gen. Biog. Hutchinſon, Med. Biog.

Hodges, William, R. A. a landſcape painter, who received his tuition in the art from Wilſon, whom he aſſiſted for ſome time, and under whom he acquired a good eye for colouring, and great freedom and boldneſs of hand; but unluckily, like too many pupils, he caught the defects of his maſter more powerfully than his beauties; and was, in conſequence, too looſe in his definition of forms, by which means, that which added grace to the works of the maſter, became ſlovenlineſs in the pupil. "Hodges had the boldneſs and neglect of Wilſon, but not genius enough to give authority to the former, or make us forgive the latter: too inaccurate for ſcene-painting, too mannered for local repreſentation, and not ſublime or comprehenſive enough for poetic land-ſcape; yet, by mere deciſion of hand, nearer to excellence than mediocrity; and, perhaps, ſuperior to ſome who ſurpaſſed him in perſpective, or diligence of execution." He accepted an appointment to go out draughtſman with Capt. Cook on his ſecond voyage to the South ſeas, from which he returned after an abſence of three years, and painted ſome pictures for the admiralty, of ſcenes in Otaheite and Ulietea. Afterwards, under the patronage of Warren Haſtings, he viſited the Eaſt Indies, where he acquired a decent fortune. On his return home, after practiſing the art ſome time, he engaged in commercial and banking ſpeculations; which, not proving ſucceſsful, he ſunk under the diſappointment, and died in 1797, aged 53.

HODMAN, a cant term formerly uſed for a young ſcholar admitted from Weſtminſter-ſchool to be ſtudent in Chriſt-church, in Oxford.

HODOMETRICAL (of ὁδος, *way*, and μετρω, *I meaſure,*) *method of finding the longitude at ſea,* is that of the computation of the meaſure of the way of a ſhip between place and place, *i. e.* obſerving the ſeveral rhumbs or lines in which the ſhip ſails, what way ſhe has made, or how many leagues and parts of a league ſhe has run. This method is liable to great errors.

HODY, Humphrey, in *Biography*, was born at Odcombe, in Somerſetſhire, in 1659, of which place his father was rector. He was educated at a grammar-ſchool, and completed his ſtudies at Wadham college, Oxford, where he took his degrees, and was afterwards choſen fellow and tutor. In 1681, and 1682, he wrote his learned diſſertation on Ariſteas's Hiſtory of the Seventy-two Interpreters, which was intended to ſhew, that it was the invention of ſome Helleniſtical Jew, and written on purpoſe to recommend and give greater authority to the Greek verſion of the Old Teſtament, which, from this ſtory, has received the name of Septuagint. In 1689, Mr. Hody wrote the prologomena to John Malela's "Chronicle," which was publiſhed at Oxford two years afterwards. In 1692, he took his degree of D. D., and ſoon after publiſhed a treatiſe entitled "The Reſurrection of the ſame Body aſſerted." After this he obtained ſome conſiderable preferment in the church, and in the beginning of the reign of queen Anne when the controverſy concerning the powers and privileges of an Engliſh ſynod, or convocation, was warmly agitated, Dr. Hody publiſhed "A Hiſtory of Engliſh Councils and Convocations, and of the Clergy ſitting in Parliament, in which is alſo comprehended the Hiſtory of Parliaments, with an Account of our ancient Laws." This work brings down the hiſtory from the firſt ſynod, which is mentioned to have been held in this iſland, *viz.* that of Verulam, in 446, to the beginning of the reign of Henry VIII. Dr. Hody was author of many other learned works, and left behind him, which was publiſhed in 1742, a work in MS. entitled "De Græcis illuſtribus Linguæ Græcæ Literarumque Humaniorum Inſtauratoribus, eorum Vitis, Scriptis et Elogiis." This work conſiſts of two books, of which the firſt treats of the learned Greeks who came to Italy before, and the ſecond, of thoſe who came after the taking of Conſtantinople. Dr. Hody died in 1706, in the 48th year of his age.

HOE, in *Agriculture,* the uſual name of a tool employed in tillage huſbandry, well known to the modern farmer, and which is conſtructed in different modes and forms, in order to ſerve different purpoſes in cultivation. Tools of this nature are principally diſtinguiſhed into two kinds, from the differences in the methods in which they are made uſe of; as *hand* and *horſe* hoes, the former ſort being uſed by the hands of the labourer, while the latter are wholly employed by the powers of the horſe. Hand-hoes are, likewiſe, chiefly had recourſe to where the crops are put into the ground in the broad-caſt, or narrow-row ſyſtems, but horſe-hoes in ſuch as are ſown in diſtant drills in a regular manner in regard to the rows or lines. Thoſe of the latter ſort are far more powerful in their work than thoſe of the hand kind, and capable of executing the buſineſs with much greater diſpatch.

Hoe, *Hand.* The variations in the ſhape and conſtruction of this kind of hoe are numerous, but the old ſquare hand-hoe, which is in uſe for a great variety of purpoſes, ſuch as thoſe of common hoeing, thinning, and ſetting out different crops of the turnip and other ſimilar kinds ſown in the broad-caſt mode, as well as occaſionally for ſtriking out the ſupernumerary plants in ſuch as are cultivated in the row or drill method, is commonly well known to the farmer. It is in general conſtructed of a ſquare piece of thin iron, which has a hole and ſort of ſocket formed in the middle, on the upper ſide, into which the handle is faſtened; though in ſome inſtances a kind of hoop is formed, which is attached to each extremity of the ſquare part, the middle conſtituting a ſort of ſocket which receives the handle. Some conſider this as forming an improvement in the tool, by admitting the mould to paſs through the part which conſtitutes the bow.

Theſe kinds of tools are alſo made of different dimenſions, in order to their more ready application to different ſorts of crops and grounds. The moſt uſual ſizes are thoſe given below:

Dimenſions of Hand-Hoes.

2 inch hand-hoes.
3 inch ———
4 inch ———
5 inch ———
8 inch hand-hoes.
9 inch ———
10 inch ———
12 inch ———

It is uſual to employ the two firſt deſcriptions of hoes in the more early growth of ſeveral ſorts of field crops, ſuch as thoſe of the carrot and parſnip kinds, as well as occaſionally for wheat and other grain crops. The four-inch ſize is alſo ſometimes uſed for theſe, as well as the firſt hoeings of turnip crops and others of the ſmall ſeed kind. Eight and nine-inch hand-hoes are more commonly made uſe of for the later turnip crops, and for thoſe of the pea and bean ſorts, on moſt kinds of ſoil.

The laſt two ſizes of hand-hoes are for the moſt part employed for the early turnip crops, on ſuch ſoils as are of a ſandy or loamy quality and free from ſtones; and, likewiſe, occaſionally on ſuch as are of a flinty nature.

For the purpoſe of thinning out ſuch plants as ſtand in a very cloſe ſtate, in a more perfect and effectual manner than by the common hoe, in various kinds of crops, a triangular tool of this ſort has been conſtructed and had recourſe to, which is found to anſwer well. In it one of the points of the angles is placed in a downward direction, by which means the workman is enabled to cut out the uſeleſs plants with a conſiderable degree of exactneſs.

And another tool of this nature, which has two cutting points for breaking up and dividing the ground, has been found very beneficial in different intentions. It is ſaid to be in great uſe in Portugal, and that, from its weight and conical ſhape, as well as the circumſtance of the handle being light and ſhort, it executes its work to a good depth, without any unuſual exertion of the perſon who makes uſe of it. It is in that country chiefly had recourſe to in breaking up the ſtrong grounds of their vineyards, which could not, it is ſuppoſed, be effected by our common hand-hoes. This hoe has, likewiſe, been ſuggeſted as capable of being of great utility in the digging and cultivating of ground in ſteep hilly and mountainous tracts, as well as in the making of compoſt manures of lime and earth, in the corners of fields where the plough is incapable of being made uſe of for the purpoſe; and in all ſteep ſituations where the ſpade cannot be employed. It is not improbable but that it may alſo be beneficially uſed in digging over the head-lands in arable fields, as well as in orchard grounds, and among plantations of trees in various caſes.

However, in order to effect the work of field culture in a more perfect and expeditious manner, than by means of common hand-hoes, other improved ſorts of them have been lately invented by Mr. Ducket, junior, which execute the buſineſs on ſeveral rows at the ſame time, and which are capable of being varied ſo as to ſuit different objects and purpoſes of huſbandry. They have been had recourſe to on ſuch lands as are of the more light quality with very conſiderable ſucceſs. They conſiſt of a kind of *double* and *treble* hoes. By the firſt of the latter deſcription three rows are capable of being finiſhed at the ſame inſtant, the labourer who employs it advancing in the ſame manner as with the common hoe. Its weight, when furniſhed with the three heart hoes, is 7lb. 9oz. but which is capable of being wrought by even a woman who is accuſtomed to ſuch labour. By this means, it is ſuggeſted, a much finer tilth is ſtricken into drills for receiving different kinds of ſeeds, and more expeditiouſly than by the angle of the common hoe on any line of direction; and that when one drill has been correctly opened, the others will of courſe be formed with accuracy.

In a ſecond form of this improved hoe, the ſhares are diſtributed in the manner for drawing, the workman in uſing it moving backward; and in the intention of adding more preſſure without ſubjecting the wriſt to fatigue, the contrivance of a rope is had recourſe to, which paſſing round the workman's waiſt, draws from the part where the hand would have acted.

Its weight, with two twelve-inch hoes, is 7lb. 3oz. It has another diſpoſition of the hoes, which is moſtly employed in the making of trenches in mellow fine lands, for the reception of manure in the planting of potatoes and other ſimilar crops. Theſe drills or trenches are formed with much expedition by ſtriking in a line, bringing the mould up into a ſort of half ridge, and then finiſhing it by turning and going back. Its weight, with three ſtraight ſix-inch hoes, is 6lb. 11oz.

There is ſtill an additional form of this improvement of the common hand-hoe, in which there are two outward hoes, a ſpace being left in the middle betwixt them, by which the tool is enabled to execute its work on each ſide of a drill or row of any kind of crop without difficulty or danger of hurting it.

It is aſſerted by the inventor, that by the uſe of this hoe two acres of barley are capable of being hoed in the courſe of a day, and that good work is made with it on wheat and oat crops.

The *double* hand-hoe is ſtill occaſionally in uſe in ſome places, and is a tool that is ſimple in its conſtruction, and capable of being had recourſe to with benefit on ſoils of the more open and light deſcription.

Hoe, *Breaſt.* This is a tool of the hoe kind that has been adviſed by ſome, as more adapted to particular uſes than thoſe of the ordinary hand ſort, as for the hoeing between the rows of ſuch grain crops as are diſtributed at narrow diſtances, as performing the work not only with more expedition, but in a more effectual manner.

Hoe, *Macdougal's.* This is a tool of the hoe deſcription, which bears the name of its inventor or improver, and which has ſomewhat the form of a ſmall light plough, being drawn by a labourer, who is attached to it by a proper contrivance before, and directed by another behind. It is a very convenient and uſeful implement in many inſtances, eſpecially where the crops ſtand at conſiderable diſtances in the rows, ſo as to permit it to work freely. As open wheels are conſtantly liable to clog and fill up, it might probably be an advantage in this caſe to have the wheel made perfectly ſolid.

Hoe, *Horſe.* This is a very powerful implement of the hoe ſort, which is now much in uſe for the cultivation of moſt ſorts of crops, that are ſown in the drill or row method.

The tools of this deſcription that are employed in the different counties of the kingdom, are extremely various in their nature, form, and conſtruction, according to the uſes and purpoſes for which they are deſigned, as well as the peculiar ſtates and circumſtances of the lands on which they are to be employed, and the nature of the drill machines by which the crops are put into the ground. They alſo differ greatly in their weights and ſizes, as well as in the ſhapes of the cutting parts or hoes.

But all the different kinds of hoes of this nature have a very great ſuperiority and advantage over thoſe of the hand kind when properly formed, not only in point of diſpatch from their working upon a great number of rows at the ſame time, but from their executing the buſineſs to a better depth, and in a much more perfect manner. It is obvious, that by means of this deſcription of hoe, the earth can be much more completely ſtirred and looſened about the roots of the plants, and the ground be kept far more clean and free from weeds than by the hand method, while the ſaving in labour and expence is very conſiderable. There can, therefore, be no doubt of the propriety of uſing them as much as poſſible in the buſineſs of modern huſbandry.

Among the numerous implements of this kind which have been lately invented, the *expanding horſe-hoe*, and ſix-ſhared horſe-hoe, deſcribed in Mr. Amos's work on drill-huſbandry, are deſerving of notice, as being practical tools. The former has a ſuperiority in many caſes from the circumſtance of its being formed with expanding ſhares, which can be regulated to ſuch diſtances as may be proper within the limits of twelve and thirty inches. It is found extremely beneficial in the hoeing of bean crops, whether ſown in drills or equi-diſtant rows. Likewiſe, in crops of the potatoe and cabbage kinds. The inventor has had much recourſe to it for theſe purpoſes in the county of Lincoln.

The ſix-ſhared horſe-hoe may likewiſe be very uſeful in different ſorts of grain-crops, which have ſmall intervals, ſuch as thoſe of nine inches, from its being capable of regulation in ſo far as the rows are concerned. It has alſo been found capable of application in the preparation and cultivation of lands of the ſtiff, ſtony, and gravelly deſcriptions, as well as in ſuch as are greatly over-run with weeds and other ſimilar trumpery, by means of having recourſe to teeth, tines, or other coulters, in the room of the triangular hoes; which ſhould be fixed in the tool in ſuch a manner as that they may not only cut and divide the more ſuperficial parts of the ſoil, but alſo effectually ſtir it below.

A convenient horſe-hoe, for the purpoſe of hoeing a number of rows at the ſame time, is capable of being furniſhed by the drill-machine, improved by Mr. Cook, merely by removing the drill-coulters, and ſupplying their places with proper ſhares for hoeing. But in doing this it muſt be obſerved, that ſoils of different qualities and textures will require ſhares of different forms and ſizes, but which can only be regulated by means of experience in any particular ſort of land. In ſandy, loamy, and all light ſorts of ſoil, or ſuch as have been perfectly broken down and reduced by tillage, ſhares from five to ſix inches in breadth for nine-inch drills, and thoſe of eight inches in breadth for twelve-inch drills, will perform their buſineſs in a ſafe and effectual manner. But in ſtrong clays, which are intermixed with pebbles, the ſhares of the hoes muſt not have ſo much breadth; and it is not improbable but that there may be ſome ſoils wholly incapable of flat-hoeing. Where, however, the texture of the ſoil in the intervals of the rows of grain is capable of being torn and ſtirred by long narrow plates of iron, having the forms of points or chiſſels introduced into the ſhanks of the hoe-ſhares, inſtead of the hoe-plates, there will be very great advantage obtained in the work. The hoe-plates are capable of being regulated ſo as to operate to a greater or leſs depth by different contrivances. It is found that ground cannot lie in too level a ſtate on the ſurface for the work of effectual and expeditious horſe-hoeing. In caſes, however, where the ridges or lands are in ſo convex or rounded a ſtate, as that the whole of the hoe-plates are incapable of performing the work in an equally deep manner in the ſame operation; ſuch as cannot be rendered uſeful may be taken out and laid by.

It is ſuggeſted by the improver of this horſe-hoe, that it is capable of being applied to ſeveral other beneficial purpoſes, in addition to that of hoeing drilled corn crops, ſuch as cutting up the rows of ſtubble as ſoon as the produce has been removed, with all ſuch weeds as may have eſcaped the hoe, and the ſtirring of ſummer-fallows, &c. With one man, two horſes, and a boy, it is ſaid that ten acres are capable of being wrought over in the courſe of a day; which is a great convenience, eſpecially in the buſy harveſt ſeaſon, when it would be wholly impoſſible to ſpare ſuch a number of men and horſes as would be neceſſary to effect the buſineſs with common ploughs. The ſame expeditious method is alſo capable of affording very great advantages, in cutting up the ſtubbles, either before or directly after the crops have been taken away, as time may be thereby gained for a ſecond ſowing of graſs-ſeeds where the firſt may have miſſed, and on cole, rape, and turnips, for the food of ſheep or neat-cattle, during the winter or ſpring.

Another ſimple and convenient tool of this deſcription, which has been lately employed with ſucceſs, is the *drill horſe-hoe*. It has been uſed in hoeing and cleaning drilled wheat crops with conſiderable advantage, in the practice of I. C. Curwen, eſq, in Cumberland, who ſtates, that "the ſimplicity and eaſe with which it is worked, has enabled him this ſeaſon to give his wheat-crop, which exceeds one hundred acres, two cleanings, at an expence ſomewhat leſs than a ſhilling per acre each operation; a man and boy, with one horſe, being able to clean above ſeven acres per day. The direction of the harrow, to prevent its injuring the grain, is effected by an alteration of the chain, by which it is attached to the wheels. The diſtance of the other teeth from the centre tooth muſt be regulated by the width of the drills. In caſe they exceed a foot, the harrow ſhould be broader, to admit of another row of teeth. To clean at nine inches, two inches and a half are allowed on each ſide of the centre tooth, by which means every part of the earth is cut between the rows of grain. The ſize and ſtrength of the teeth muſt be regulated by the nature of the ſoil."

Upon the utility of this hoe, Mr. Dykes has remarked, "that its effects appeared to him moſt highly beneficial, in clearing away in the ſpring all the weeds that had grown during the winter, amongſt the wheat, without the leaſt injury to the grain; and alſo in raiſing up the top ſoil, which had become ſad and heavy, and thus enabling the ſpring ſhoot to take root more eaſily; and, at the ſame time, it covers the roots of the corn with freſh ſoil, which are often left quite bare by the waſhing of the rains in winter, and ſubject to be killed by the froſts. It alſo enables the farmer to ſow his barley much earlier than he could broad-caſt, as it will both clear the corn previous to ſowing the graſs-ſeeds, and afterwards harrow them in." Indeed the advantage has appeared ſo great, that he has been induced to ſow the corn on his fallows by means of the drill.

A practical implement of this ſort has likewiſe been lately contrived by Mr. Waiſtell, which he denominates a *horſe-hoe*. In this tool, by combining the powers of the hoe and harrow a convenient and uſeful machine is afforded for working the intervals of drilled turnip, and other crops, that have ſufficient widths in the rows for admitting its action.

Its various uſes are, that "it enables the farmer to cultivate thoſe intervals as completely as a well-wrought fallow, ſo long as the horſe can travel therein without injury to the growing crop. It is not aſcertained who was the original inventor of this tool, but the firſt Mr. Waiſtell ſaw was at Weſt Park, in the vicinity of Barnard Caſtle. That in his poſſeſſion was brought from Carliſle, and great numbers have been ſince made from it. They anſwer perfectly for turnip crops, ſown at twenty-ſeven inches diſtance in the rows, and are greatly in uſe for that ſort of culture.

There are ſtill a great many other ſorts of horſe-hoes, but it is not neceſſary to take notice of them in this place, as they will be conſidered in ſpeaking of the operations which they are particularly calculated to ſerve.

Hoes of theſe ſeveral kinds may be ſeen by conſulting the figures in the plate belonging to this article.

Hoe, in *Gardening*, the common name of an uſeful and well-known garden implement.

Theſe tools are of different kinds, as *drawing* and *ſcuffling*, each of which has different ſizes or dimenſions.

The firſt ſort is fixed with its edge inclining a little inward; the workman, in uſing it, drawing it towards him. It is one of the moſt uſeful implements of gardening for many purpoſes, both for general hoeing, and in drills for ſowing many ſorts of ſeeds, looſening the earth about the plants, and moulding up the ſtems of them, as well as hoeing down weeds between all ſorts of plants that ſtand diſtant enough to admit it. It is the beſt adapted of any kind for thinning out eſculent crops to proper diſtances, to acquire their proper growth, ſuch as onions, carrots, parſnips, turnips, ſpinach, &c. And of this kind there ſhould be three or four different ſizes, from ſix inches width down to two inches, or leſs.

The firſt ſize is a large hoe for common uſe, about ſix inches long in the plate, by three or four broad, fixed on a long handle for both hands, and is the proper ſort to uſe for all common hoeing-work, and for drawing drills for ſowing peas, beans, kidney-beans, &c. It is the moſt eligible ſized hoe of any for broad-hoeing, between rows of all thoſe kinds of plants, and all others that ſtand diſtant enough, either in rows or otherwiſe, for the hoe to paſs between them, both to cut down weeds and looſen the ground, and to earth up the ſtems of the plants, and for all other purpoſes of hoeing where the plants ſtand diſtant, both in the kitchen and pleaſure-garden.

The ſecond ſize ſhould be about four inches in the plate longways, and the ſame breadth as the above. It is uſeful for drawing drills, and for hoeing among various plants, where the former ſort of hoe cannot be commodiouſly employed; as well as to thin ſome ſorts of eſculent crops that require moderate diſtances, ſuch as Dutch turnips, general crops of carrots, parſnips, &c. It is alſo a proper ſized hoe for hoeing common flower-beds and borders, &c. in moſt inſtances.

The third ſize ſhould be two inches and a half, or not more than three inches broad in the plate; and be fixed on a ſhort handle to uſe with one hand in ſmall hoeing, thinning out ſeveral ſorts of eſculent crops, and other work among cloſe-growing plants. A ſmaller one ſhould alſo be fixed on a longer handle, to uſe two-handed in hoeing borders, and other compartments of ſmaller plants ſtanding near together, both in the kitchen-ground, flower-garden, &c. This ſized hoe, on a ſhort one-handed handle, is likewiſe particularly uſeful for ſmall-hoeing, moulding, and thinning out many kitchen-garden crops in young growth, ſuch as onions, leeks, carrots, parſnips, ſpinach, &c. to cut them out to the proper diſtances. It is alſo a very convenient ſize for uſe on many other occaſions of hoeing; and for drawing ſmall drills for ſowing many kinds of ſeeds, and hoeing up flower-beds, &c. where the larger hoes cannot be readily admitted between the plants, ſo as to ſtir the mould effectually about them.

The fourth ſize ſhould be about two inches wide, and fixed in a ſhort handle. It is proper for ſmall-hoeing onions and ſmall crops of carrots, radiſhes, &c. the firſt time where they ſtand pretty cloſe, and where it is not deſigned to thin them out at once to their full diſtance, but to leave them rather thickiſh for culling, &c.

The edges of the hoes ſhould conſtantly be kept ſharp by occaſional grinding, that they may cut clean and freely.

The ſecond ſort, or ſcuffling-hoe, is commonly called a *Dutch-hoe*. It is fixed with the edge outward, on the end of a long handle, ſo as that the perſon uſing it may puſh it from him going backward, and never treading on the hoe-ground, as with the drawing-hoe. In regard to ſize, it ſhould be from about four to ſix or eight inches wide, open in the middle, for the mould and weeds to paſs through, ſo as not to be drawn in heaps; having a long ſocket at the back part, in which to fix the handle, which may be five or ſix feet in length.

This is very proper for ſcuffling over any piece of ground to deſtroy weeds, that is clear from crops, or between crops that ſtand wide, with which a perſon may make conſiderably more expeditious work than with a drawing hoe, eſpecially when the weeds are not ſuffered to grow large; in which caſe, one man can often do as much as two with the other ſort. It is not proper for hoeing out crops of eſculent plants, or for earthing up the ſtems of plants, nor for hoeing where the plants ſtand cloſe. But it is very uſeful for cutting down weeds in ſhrubberies and wilderneſs quarters, where the ſhrubs ſtand diſtant from one another. And it is the beſt ſort of any for ſcuffling over ſand-walks, or others made of looſe materials, in order to deſtroy weeds, moſs, &c.

When of a ſmall ſize, it is alſo found uſeful to run over flower borders, to cut up ſtraggling weeds; as, being fixed on a long handle, the work may be effected by ſtanding in the walks, without treading on the borders or walks, and thereby doing injury.

There is alſo a ſort of triangular hoe, which has been lately found very uſeful in hoeing many ſorts of ſmall crops that ſtand rather cloſe.

HOEDIC, in *Geography*, a ſmall French iſland in the Engliſh channel, near the coaſt of the department of Morbihan; about 9 miles E. of Belle-iſle, and 12 S.E. from the peninſula of Quiberon; on it are a town and village of the ſame name, and a fort. In 1746, this iſland was taken by the Britiſh. N. lat. 47° 41′. E. long. 2° 46′.

HOEING, in *Agriculture*, the work of breaking down, dividing, and rendering the particles of the mould or ſoil fine, by the uſe of tools contrived for the purpoſe, between the rows of drilled grain crops, or thoſe of other ſorts, ſet in rows at ſtill larger diſtances.

It is one of the moſt uſeful and important proceſſes, where crops are ſown or ſet in the drill or row method, and which ſhould conſtantly be well attended to, and executed.

The advantages of the hoe culture are, in general, conſidered to be extremely numerous; it completely deſtroys weeds; increaſes the means of the plants ſupplying themſelves with food, greatly promotes the fertility of the land; forwards the proceſs of vegetation; and leaves the ſoil in a great part prepared for ſucceeding crops. As rain, ſnow, and dews are capable of being taken up with avidity by the mould of the ſoil, while it is preſerved in a looſe, porous, and open condition, though in the contrary ſtate, or that of its being in a hard-bound, firm ſituation, they ſeldom reach much below the ſurface, being ſpeedily again taken up into the atmoſphere by the effects of the ſun and wind, producing little or no benefit; the work of hoeing muſt obviouſly, in this point of view, be of great utility. And accordingly it is found highly efficacious on ſtrong, ſtiff, loamy ſorts of land; while in thoſe of a very light open texture it is often hurtful, by ſuffering the moiſture and other elaſtic matters to eſcape too freely, when too much employed.

In conducting the work of hoeing, the ground ſhould be in a medium ſtate of dryneſs. Light dry ſoils are moſtly capable of being hoed at any ſeaſon; but ſuch as are of an adheſive compact quality, can only be hoed with benefit, at particular periods, when the mould of them is in a looſe friable ſituation.

In the hoeing proceſs, it is neceſſary to execute the buſineſs in different ways, according to the nature and circumſtances of the land. Upon the more ſtiff, heavy, loamy ſorts of ſoil, which are very apt to produce abundance of weeds, it will be found neceſſary to repeat it more frequently than on others of the more light and open deſcriptions. The hoes ſhould likewiſe be heavier, and the ſhares ſtronger, for the former than the latter. In grain, and ſmall ſeed crops, when drilled at narrow diſtances, the work of hoeing ſhould be performed by means of ſmall ſhares that bear a due proportion to the width between the rows. But for other larger ſorts of crops that are drilled or ſet at much wider diſtances, larger and ſtronger tools are proper.

Many farmers are of opinion that hoeing is greatly more beneficial when executed with horſe-hoes, than any of thoſe of the hand kind, from their looſening the ſoil more deeply, and thereby providing more nouriſhment for the uſe of the crops. Hence, it is ſuppoſed, ariſes “the vaſt importance of the operation of horſe-hoeing, during continued drought in the ſpring or ſummer; and to this cauſe, in a great part at leaſt, it may probably be owing that lucern, uſually ſowed and horſe-hoed, is ſaid to endure drought ſo much better than natural graſſes, and to appear green and flouriſhing whilſt theſe are withered and burnt up. The almoſt inſtantaneous benefit conferred, by this operation, upon cabbages, which are root-bound from a baked ſoil, or upon wheat which appears yellow and ſickly in the ſpring, is its beſt recommendation.” Theſe crops may, it is ſaid, “be ſeen, after being worked in the rows, from a withered ſickly hue, and flagging condition, turn erect, and change their colour to a deep and flouriſhing green within twenty-four hours. Nay, of ſuch importance is the operation of deep and effectual hoeing held by experienced people, that a Kentiſh farmer has been known, in a time of great drought, to ſend his men with their ſpades into the alleys of peas, being afraid of damage from horſe-work.”

With regard to the number of hoeings that may be neceſſary for different ſorts of crops under the drill ſyſtem, it muſt of courſe vary greatly according to the particular circumſtances of the different caſes. It is uſually, however, about three, four, or even five, in remarkable inſtances. But it is chiefly to be regulated by the diſpoſition of the land to throw up weeds; where this is conſiderable, more hoeings will conſequently be required, as no weeds ſhould ever be allowed to riſe.

In reſpect to the proper periods of hoeing, there is conſiderable diverſity of opinion, eſpecially as to grain crops, and thoſe of ſome other kinds.

In wheat, when ſown ſufficiently early to admit of the work being done in the autumn, the firſt hoeing is adviſed never to be executed until the plant has acquired more than one blade, and it may be delayed till it has four or five leaves, in caſe that no particular occaſion for it is ſeen, and that it be performed before the winter ſets in.

The method of hoeing is differently executed in different caſes. The author of the horſe-hoeing huſbandry recommends, that the firſt operation ſhould be performed from the rows of the plants, in one bout of the machine, by which means a ridge is left in the middle of the interval, and a furrow or channel on each ſide of it, having the row of plants between, by which the ſnow and rains are caught in the winter, and much benefit thereby produced, as well as by the greateſt poſſible ſurface of the ſoil being expoſed to the influence of the atmoſphere. It has been contended by the above writer, that, for the firſt time, the work can ſcarcely be done to too great a depth, or too near to the rows, provided that the plants are not injured, or rooted up, as by laying the roots almoſt bare in this way, and expoſing them to the action of the froſts, no ſort of harm is ſuſtained by them. This is, however, a practice, the utility of which may be juſtly diſputed, as it is more natural to ſuppoſe that benefit may be derived from the mould being ſtirred and laid up to the ſtems of the plants, than by expoſure during the rigours of ſuch ſeaſons. And it is even admitted, that much caution is neceſſary in approaching the rows of plants, in performing this ſort of work on very light ſoils. It is alſo ſuggeſted, as a common fault among workmen in employing the hoe plough, that they merely ſkim up and down the middle of the intervals between the rows without going ſufficiently near them, or ſufficiently deep; and it is adviſed, as a great improvement of the cuſtom, to trench or draw another furrow to a proper depth, if practicable, immediately, or otherwiſe before the ridge be turned back in the ſpring. In this way the plants are left, as it were, on the brink of a trench, by which means they are preſerved conſtantly dry and free from ſtagnant moiſture, being, at the ſame time, ſheltered by the ridge thrown up in the alley.

In uſing the drill huſbandry on ſtrong ſoils, there may often be danger in protracting the firſt horſe-hoeing to too late a period, on account of the ground being apt to become too moiſt for performing the buſineſs in an effectual manner.

The work of horſe-hoeing in the ſpring may be begun “as ſoon as the froſts are out of the ground, and the ſurface mould is ſufficiently firm to ſupport the animals without injury in its execution; the ridges between the rows are now to be divided and turned back, the finely reduced mould from the action and influence of froſt and ſnow being laid to the roots of the plants, by which an abundant ſupply of nutritious matter is taken up. It is not believed that even the ſmalleſt injury is done to the roots, by the breaking and tearing of the innumerable threads and filaments which branch out on every ſide, as nature, in a very ſhort time, not only remedies the miſchief, but provides abſorbing mouths in proportion to the ſupply of nouriſhment that is made. It is ſuggeſted that the farmer muſt conſtantly be the judge of the neceſſity for light harrowing and rolling, before the work of ſpring-hoeing the rows is begun.

The number and diſtances of the ſucceeding horſe-hoeings muſt, in a great meaſure, be governed by the circumſtances of the land, and the convenience of the cultivator, but they have chiefly two objects in view; firſt, that of turning in the weeds the moment they are in the proper condition; and ſecondly, that of moving the ſurface mould before it becomes too much baked, and impervious to the dews: the latter of theſe points muſt be carefully attended to in dry parching ſeaſons, as the weight of the crop depends greatly upon it. The advantages of the drill ſyſtem are here likewiſe clearly evident. There may be a ſtill further neceſſity for an additional ſtirring, in ſuch ſoils as are much exhauſted or impoveriſhed, ariſing from the crops having taken up the chief of the nouriſhment which was provided by the former hoeings, conſequently a new earthing up of freſh mould near the period of their coming to perfection may be of great ſervice. It is conceived that ſlight hoe-ploughing can never be in the leaſt injurious, at whatever ſeaſon it may be executed; but deep working in this way ſhould never be permitted near the rows of the plants either in the ſpring or the ſummer months. However, the middle part of wide intervals may be wrought to a good depth, as, in this caſe, the plants are left well earthed up at the laſt hoeing.

In reſpect to the modes of executing the work of horſe-hoeing, it is hinted, that “the old method of very wide intervals for the horſe-hoe, whilſt the ſeven-inch rows upon the ridges were truſted entirely to the operation of the hand-hoe, ſeems now to be exploded, and to have given way to the improvement of horſe-hoeing the rows in a conſiderable number at one time.” It is probable that this expeditious method was firſt introduced by Ellis and Ducket. The ſuperiority of ſuch a practice over hand labour cannot be diſputed; but when had recourſe to on ſtrong rough lands, its powers may be queſtioned with propriety, and a preference be juſtly given to the regular and effective working of the hoe-plough. Upon ſuch clayey grounds, deep and effective pulverization is of great conſequence, ſlight ſurface working producing but little benefit, the earth below being left in a hard unreduced ſtate, almoſt wholly unfit for the purpoſes of vegetation.

The work of horſe-hoeing muſt, however, in a great meaſure, be regulated, in all caſes, by the circumſtances of the ſoils, and the particular modes of drill-ſowing that may have been employed.

It is ſtated by a late able writer, that "early in March Mr. Coke uſes the hand-hoe, which, for hoeing the rows of wheat and peas, is about ſix inches wide; and for hoeing thoſe of barley, about four inches wide. By this hoe, the ſurface is not only turned over, and the weeds between the rows rooted up, but the mould is alſo accumulated about the roots of the growing corn, and covers, and conſequently deſtroys, the low growth of poppies amongſt them, which are a very frequent weed in that part of the country. A ſecond hoeing is performed about the middle of May, and the ſoil is again not only cleared from weeds, but accumulated againſt the riſing corn, each of which hoeings coſt about twenty pence per acre. Nevertheleſs, it is ſuggeſted, that ſome attentive agricultors uſe the horſe-hoe belonging to Mr. Cook's drill machine, though the rows of corn are but nine inches from each other; and aſſert that this occaſional trampling of the horſe on the young plants is of no very ill conſequence, a circumſtance well worth obſerving, as it removes the principal diſadvantage of the horſe-hoe, which conſiſts in the too great diſtance of the alternate rows of the corn plants." It is further ſtated, that "by the earth being thus accumulated againſt the roots of the corn, it is ſaid to tillure, or tellure, much; that is, to throw out four or ſix ſtems, or more, around the original ſtem, and thus to increaſe the number of ears, like tranſplanting the roots; inſomuch that Mr. Coke obtains by this method between four and five quarters of wheat on every acre, which, in the broad-caſt, did not yield more than three quarters an acre, beſides ſaving a ſtrike and a half of the ſeed corn, unneceſſarily conſumed in the broad-caſt method of ſowing. To this ſhould be added another advantage, that as the land is thus kept clear from weeds, and has its ſurface twice turned over, and thus expoſed to the air, it is found to ſave one ploughing for the purpoſe of a ſucceeding crop of turnips." But whether this tilluring of the plants may be really beneficial, without hurting their roots by too much exhauſtion, has not been hitherto ſatisfactorily ſhewn.

A late writer, who objects to the proceſs of hoeing, as practiſed by Tull, Chateauvieux, and others, as being very imperfect, by leaving the roots of the plants too much expoſed and ſubject to the effects of the drying ſummer winds, as well as various other cauſes, in the firſt operation of the buſineſs, ſuppoſes, that all the different proceſſes of horſe-hoeing may be performed in an equally effectual manner, by the common ſwing-plough, as by any of the hoe-ploughs which are generally employed. The mode of uſing the ſwing-plough in this ſort of work, is deſcribed and explained in the ſecond volume of "Recreations in Agriculture," at conſiderable length, with a plate.

But notwithſtanding the eaſe, convenience, neatneſs, and diſpatch with which the work of hoeing may be executed, either by means of ploughs of the common hoe or ſwing deſcriptions in ſuch ſorts of crops as ſtand in need of wide intervals, as thoſe of potatoes, cabbages, beans, and others, which are ſimilar in their nature and habits of growth, they are not by any means properly adapted for executing the buſineſs in ſuch crops as are put into the ground at narrow diſtances, ſuch as thoſe of the grain kind. In theſe caſes, ſuch hoe machines as work between many different rows at the ſame time, are commonly found the moſt proper and convenient.

Other implements, ſuch as thoſe of the cultivating and ſcarifying kinds, may be had recourſe to with much advantage, in many caſes, in the early ſpring, in the view of looſening and ſtirring the earth about the roots of theſe ſorts of crops.

It has been ſtated by a writer on drill huſbandry, that in performing the work of hoeing in wheat crops, as that plant has two ſorts of roots, namely, the *ſeminal* and the *coronal*, the latter of which rarely ſhows itſelf until towards the end of March, or the beginning of the following month, that is the proper period for aiding the efforts of nature; which is adviſed to be done by means of paſſing over the field with a pair of light harrows, and in this way not only deſtroying the weeds, but affording an earthing-up to the coronal roots of the plants. As ſoon as this harrowing has been executed, a roller ſhould be immediately paſſed over the field, in order to render the ſoil firm about the roots of the crop, as well as to prepare for a ſecond hoeing; but this proceſs may not be neceſſary except in the more light kinds of ſoils. About the beginning of May, and ſometimes ſooner, it is ſuggeſted, that the ſecond hoeing ſhould be undertaken by the uſe of the ſix-ſhared horſe-hoe or the breaſt-hoe. The latter, however, only hoes one row at a time, and is of courſe very inferior to the former; which performs the work on ſix or ſeven, according to the diſtances at which the crops are ſown. Where this laſt ſort of hoe is employed, the ſeed box, &c. ſhould be wholly removed, nothing being left but the mere frame of the drill machine, to the coulter bar of which the hoes ſhould be attached. And in the execution of the work, the horſe ſhould paſs exactly in the ſame track in which it went in drilling the ſeed, one hoe leſs than the number of rows drilled being made uſe of; that interval between the breadths of the drill implement being hoed by the hand, on account of its being unequal from the unſteadineſs of the horſe; and by the workman who manages the machine keeping his eye conſtantly on one of the hoes, ſo as to preſerve it in the middle of the interval, the reſt muſt with certainty be perfectly right in their direction. In caſes where the labourer who directs the hoes wants to move them to the right or left, ſo as to keep them in the middle of the intervals, he ſhould lift up the handles in a ſlight degree at the time he moves them. But it makes no material difference, whether the coulters or hoes be uſed or not, as the manner of regulating them is equally the ſame, and the directions that have been given for the uſe of the hoes are equally applicable to the uſe of the coulters in this hoe machine.

The third hoeing is directed to be had recourſe to about the latter end of May, or the beginning of the following month, as at that ſeaſon it greatly invigorates the coronal roots of the plants, and at the ſame time promotes the growth of the ſtems or ſtalks.

And where a fourth hoeing is found requiſite, it ſhould be performed about the end of June, or in the beginning of the ſucceeding month, according to the circumſtances of the caſe. However, as there are conſiderable variations in the ſoils and ſeaſons, it is ſuggeſted as impoſſible to aſcertain with preciſion the exact period when the work ſhould be performed. Conſequently, much muſt be left to the judgment and diſcretion of the farmer; but weeds ſhould in no inſtance be ſuffered to become predominant, as thereby much injury muſt neceſſarily be ſuſtained in the crops.

When drilled crops of the wheat kind are hoed by the hand method, which ſhould perhaps be only managed in this way; it is ſuppoſed by ſome that the work ſhould be executed, as ſoon after the plants are up as poſſible, by two-inch hoes.

In the execution of this ſort of work, on crops of the barley kind, as there are likewiſe two ſets of roots, of a ſimilar nature to thoſe in wheat, as the ſeminal and coronal, the latter of which is formed about three weeks after the ſowing of the ſeed, it is ſuggeſted that upon the appearance of this root, the field ſhould be harrowed, and afterwards rolled, in order to prepare it for the firſt hoeing proceſs, and that the ſecond and third hoeings ſhould be had recourſe to at proper diſtances of time, being executed exactly in the ſame way as has been already directed for conducting the work in crops of the wheat kind.

In managing the work in oat crops, it is adviſed, that as ſoon as the coronal roots begin to ſhow themſelves, the field ſhould be harrowed and rolled as above for the firſt operation of the hoe. And that the ſecond and third hoeings, in caſes where they may be requiſite, ſhould be performed in proper times afterwards, and in the ſame method as has been directed for crops of wheat.

It has, however, been ſhewn that the work of hoeing is capable of being effected in a very exact and perfect manner, without the neceſſity of having recourſe to the uſe of hand hoes at all in any of theſe kinds of grain crops, by means of the improved horſe-hoe of Mr. Cook. See HOE.

But in drilled crops of wheat as well as barley, it is the advice of many good cultivators to have the work performed as ſoon as any weeds make their appearance, whether the horſe or hand method is had recourſe to for the purpoſe.

And in caſes of this nature, the hoes ſhould conſtantly be of the ſame ſizes with the drills, that injury may be more effectually guarded againſt. In theſe inſtances the work may frequently be executed by means of one horſe fixed to a tool that does the buſineſs on four or five rows at the ſame time, a workman directing it behind by means of the handles.

In the work of horſe-hoeing bean and pea crops, the writer of the ſame ſyſtem of "Drill-huſbandry" recommends, that as ſoon as the plants can be fully diſtinguiſhed in the rows, they ſhould be harrowed over and rolled in order to complete them for the firſt operation of the hoe. And that in caſes where the ſoil is mellow in its nature, the expanding horſe-hoe ſhould be employed about the middle of May, at which time the beans or peas will be ſufficiently eſtabliſhed in the ground, ſo as not to be injured by the free uſe of the tool; the ſhares being kept perfectly ſharp, ſo as to cut the weeds with facility, in order that the expanding harrow may bring them more completely to the ſurface, and thus finiſh the ſecond proceſs of the hoe. The crops may then remain three or four weeks, or until more weeds appear to be thrown up, when they ſhould be ſkim-hoed a ſecond time, which completes the buſineſs of the third hoeing. But in the courſe of ſome days afterwards, the rows ſhould be hand-hoed in a perfect manner, and then well earthed up, which concludes the work of the fourth hoeing. Two or three weeks after this they ſhould be again hand-weeded, and then earthed up the ſecond time, which finiſhes the buſineſs of hoeing that is uſually found neceſſary. It is adviſed, however, that if the ſoil ſhould be of a ſtiff, gravelly, or ſtony nature, the hoe-plough ſhould be had recourſe to in the ſecond hoeing, ploughing a furrow off from the beans on each ſide, ſo as to make a ridge in the intervals between the rows; by which means they will then ſtand upon a ridge of about ſix inches in width, which ſhould be well hand-hoed. About a week afterwards, the double mould boarded plough ſhould be employed, to earth up the plants in the rows. And in two or three weeks they ſhould be again hand-weeded, being earthed up a ſecond time by the double mould boarded plough as ſoon as the weeds are dead, which moſtly terminates the work of hoeing in ſuch crops.

In the buſineſs of hand-hoeing crops of this ſort, ten-inch hoes are commonly the moſt proper, the mould in the ſecond proceſs being brought up to the roots of the plants, upon which, eſpecially in peas, they ſhould be made to reſt in an inclining poſition, ſo as to afford a more complete expoſure to the influence of the ſun and atmoſphere.

In the work of hoeing drilled turnip crops, it is ſuggeſted that, as ſoon as they have got four vigorous rough leaves, they ſhould be harrowed with a pair of light harrows, and in two or three weeks afterwards the ſecond hoeing ſhould be given, either by the breaſt, or ſix-ſhared horſe-hoe, in order to cut up the weeds in the intervals, but ſuch weeds as are in or near the rows ſhould be extirpated by the hand-hoe, the turnips being thinned out at the ſame time. The third hoeing may be had recourſe to in two or three weeks after this with the ſame ſort of hoes, the rows being alſo well hand-hoed, and the turnips ſet out to their proper diſtances. And it is hinted that this method of turnip hoeing is equally applicable to the hoeing of cole, with the exception of the harrowing, which ſhould be wholly omitted.

It is adviſed by many to give the firſt hand-hoeing in the more early turnip crops, as ſoon as the leaves ſpread about four inches each way; repeating the operation at the diſtance of about a fortnight, ſo as to leave the plants about twelve inches apart; but in the later crops, the nature and quality of the land ſhould be well conſidered, and the diſtance regulated accordingly; however, eight or nine inches are quite ſufficient in general.

In carrot crops the method of hoeing is, as ſoon as the plants are from two to three inches above the ground, to have them harrowed over by a number of harrows faſtened together by a pole, ſo as to be capable of covering the ridge, the horſes being made to walk in the furrows, in order to prevent treading the ground, or doing injury to the young plants. In two or three weeks after the harrowing, the ſecond hoeing ſhould be given to clear the intervals of weeds, ſuch as are in or near the plants in the rows ſhould be cut up with the hand-hoe, and the plants thinned out at the ſame time. The crop may remain for two or three weeks in this ſtate, or until weeds begin again to appear. The hoes ſhould then be again employed, the breaſt or horſe-hoe to clean the intervals, and the hand-hoe for the rows; and where any double carrots are left, they ſhould be taken away, and ſuch plants as are to ſtand for the crop ſet out to their proper diſtances. In the execution of the work in carrot and turnip crops, the four-inch hoe is preferred by ſome for the latter, and the three-inch for the former, the plants being left in the firſt hoeing at ſuch a diſtance as may ſeem requiſite; and in the ſecond ſetting them out to that of from three to five or ſix inches diſtance, according to the nature of the ſoil.

In the buſineſs of hoeing potatoe crops, it has been ſuggeſted that, as they are in general ſet upon light mellow ſoils, the expanding horſe-hoe is well ſuited to their culture. It has the properties of being expeditious, effectual, and cheap in the execution of the work. The hoeing in this crop may, however, be well performed by the uſe of the hoe-plough, or indeed any common ſowing plough, as already noticed. It is adviſed, that as ſoon as the plants are fairly above the ground, they ſhould be harrowed once over in a place as a preparation for the firſt hoeing; and that in about two weeks afterwards they ſhould be ſkim-hoed for the ſecond operation, and in two or three weeks more again ſkim-hoed; the expanding harrow being conſtantly employed to drag the weeds out of the ground after they have been cut up by the hoe. Directly after the ſecond ſkim-hoeing they ſhould be well hand-hoed in the rows; and as ſoon as the weeds are dead, and in ſome meaſure decayed, the plants in the rows ſhould be earthed up well by the ſame tool properly prepared for the purpoſe. See Hoe.

When more weeds begin to ſhew themſelves, but before the potatoes begin to ſpread too much, they ſhould be hand-weeded in the rows, and then earthed up a ſecond time. When more weeds appear, and ſeem likely to run into ſeed before the potatoes are taken up, they ought to be pulled up by the hand, and conveyed from the field, or laid in heaps and conſumed by fire, or formed into an earthy compoſt by means of cauſtic lime, and rich mould.

In the hoeing of this ſort of crop others adviſe the uſe of eight or ten-inch hoes, as the land is more or leſs ſtony; in the firſt operation drawing up the mould ſo as to cover the roots and prevent their riſing above the ſurface; afterwards earthing them up with the mould from betwixt the rows of the plants.

In hoeing cabbage crops, it is ſuggeſted, that as the month of May is the principal ſeaſon for planting them to ſtand the winter, the work ſhould be finiſhed at that time; and that in about three or four weeks after they have been planted out, the hoe-plough ſhould be had recourſe to, ploughing off a furrow from the rows of cabbages on each ſide, ſo as to form a ſort of ridge in the intervals; the cabbages being left upon a flat ridge of ſix or eight inches in breadth. Theſe ridges ſhould be well hand-hoed, and the mould brought up well to the plants at the ſame time. When the work of hand-hoeing has been completed, the expanding harrow may be made uſe of in order to harrow the ridges in the intervals, by which the weeds are deſtroyed, and left upon the ſurface to decay.

Ten or twelve days after this harrowing has been done, the hoe-plough may again be had recourſe to, in order to turn back the mould to the roots of the cabbage plants, on each ſide of the rows: and in about a fortnight after this earthing up, the bottoms of the intervals ſhould be cleared up by the horſe-hoe or the hoe-plough, which has not only a very pleaſing effect, but is highly uſeful to the crop. It ſhould likewiſe be repeated a ſecond time when the weeds begin to ſhew themſelves, before the cabbages ſpread ſo as to prevent the horſe from paſſing in the intervals without injury. Where additional weeds are thrown up, they may be removed by hand labour, and any injurious inſects that may be preſent at the ſame time deſtroyed. The hoe-plough, or common ſwing-plough, anſwers here perfectly for the purpoſe of hoeing.

Where the hand mode is had recourſe to in executing the work of hoeing, a three-inch hoe is commonly firſt employed, and in the courſe of the fortnight or three weeks afterwards a four-inch hoe; after that the plants being uſually drawn out, and planted ſo as to give the moſt ſuitable diſtances according to the condition of the ſoil.

Although both the hand and horſe method of hoeing crops muſt frequently become neceſſary, it is evident that the latter has conſiderable ſuperiority in point of cheapneſs, convenience, and the effectual manner of executing the work. See the culture of the different grain, root, and other crops, under their proper heads.

Hoeing, in *Gardening*, a neceſſary operation performed by the hoe, to deſtroy weeds, looſen the ſoil, and mould up the ſtalks or ſtems of plants of different kinds, and thereby promote their growth.

It is an expeditious method of deſtroying weeds between all ſorts of plants that ſtand diſtant enough to admit it in the intervals and rows.

When principally deſigned to deſtroy weeds, it ſhould always be performed to ſome depth, and in dry weather, the more ſunny the better, eſpecially when the weeds are not to be raked off, that they may die as ſoon as they are cut down, or at leaſt be ſo much flagged or withered by the ſun and air as not to grow again.

This ſort of work, beſides deſtroying weeds, is likewiſe uſeful in looſening the ſurface and diſpoſing the earth to receive the greater benefit from the air, dews, rains, &c. to the great nouriſhment of all ſorts of plants, and, by breaking up the ſurface, dividing the clods, and ſtirring the earth, keeping it freſh and proving a very beneficial culture to all vegetables. In ſoils apt to bind after much wet, which cauſes the plants to appear of a ſtinted growth, hoeing is of vaſt advantage in promoting their immediate growth and future progreſs.

The application of earth about the ſtems of plants, ſuch as earthing up rows of peas, beans, kidney-beans, cabbages, cauliflowers, &c. is conſtantly of great ſervice in protecting the ſtrength and vigour of the crops, as well as in giving them a neat appearance.

It is alſo beneficial in thinning out many cloſe-ſtanding crops to proper diſtances, cutting out the ſuper-abundant plants and the weeds, and looſening the ſoil in an advantageous manner. See the particular crops.

HOEI-TCHEOU, in *Geography*, the moſt ſouthern city of the province of Kiang-nan, in China. It is one of the richeſt cities in the empire: the people are economical and temperate, but they are active and enterpriſing in trade. Their tea, varniſh, and engravings, are the moſt eſteemed in China. It has ſix cities of the third claſs dependent upon it; and the mountains which ſurround this canton contain gold, ſilver, and copper mines. N. lat. 29° 57′. E. long. 118° 14′.—Alſo, a city of China, of the firſt rank, in Quang-tong, celebrated for the fertility of the country round it, and its extenſive trade. Its juriſdiction comprehends 11 cities of the ſecond and third claſs. N. lat. 23° 1′. E. long. 114°.

HOEMAH, a town on the S. coaſt of the iſland of Bourro. S. lat. 3° 50′. E. long. 127° 22′.

HOENFURST, a town of Pruſſia, in the circle of Natangen; 26 miles S. of Brandenburg.

HOENSEE, a town of Pruſſia, in the circle of Samland; 12 miles E.S.E. of Goldap.

HOEREA, a town of European Turkey, in the Morea; 27 miles N.W. of Miſitra.

HOEROMSK, a town of Norway, in the dioceſe of Aggerhuus; 16 miles S.S.W. of Chriſtiania.

HOESSERING, a town of Weſtphalia, in the principality of Luneburg-Zelle, ſituated on the Hardan; 22 miles N.E. of Zelle.

HOET, Gerard, in *Biography*, born at Bommel in 1648, and was a diſciple of Warnard van Ryſen, an excellent painter, who had been bred in the ſchool of Poelemburg; but his genius ſoon exerted itſelf in ſuch a manner, that he was enabled to proceed happily in his profeſſion, without being indebted to any inſtructor.

When he commenced artiſt, he was at firſt invited to Cleve, where his paintings procured him very great credit; but he was afterwards prevailed on to viſit France: yet in that kingdom he had not the good fortune to meet with encouragement in any degree proportioned to his merit; and therefore he turned his attention to England, whither he certainly would have directed his courſe, had he not been diſſuaded by Voſterman, who at that time was preparing to leave the court of London. At laſt he ſettled at Utrecht, and in that city and its neighbourhood found a ſufficient number of admirers and friends who conſtantly employed his pencil; and afforded him continual opportunities to diſplay his abilities, in executing ſeveral grand and beautiful deſigns for ceilings, ſaloons, and ſuperb apartments, and alſo in finiſhing a great number of eaſel pictures for their cabinets.

The reputation of Hoet, for knowledge and ſkill in his profeſſion, was ſo univerſally eſtabliſhed at Utrecht, that he was appointed director of an academy for drawing and painting, which he conducted with great honour to himſelf, and remarkable advantage to his pupils. He had a lively imagination, a very ready invention, and a fine genius for compoſition; as alſo a nice adherence to the coſtume. His manner of painting was clean and neat, and he was thoroughly maſter of the true principles of the chiaro-ſcuro. His figures in general are deſigned with elegance, and drawn with correctneſs; his colouring is lively, natural, and full of harmony, from the judicious oppoſition of his light and ſhadow; his touch is light and firm, and his pictures have a great deal of tranſparence. His ſmall eaſel paintings are exceedingly delicate in the touch and the finiſhing; and yet his larger works are always pencilled with a freedom that is ſuitable to thoſe grander compoſitions.

Many capital pictures of this maſter are in the palace of Slangenberg; and his eminent talents may be ſeen in the grand ſtair-caſe at Voorſt, the ſeat of the earl of Albemarle. In Holland, and alſo in our kingdoms, ſeveral charming pictures of Hoet are preſerved; ſome of them in the manner of Poelemburg, and others in the ſtyle of Carel du Jardin. He died in 1733, aged 85.

HOF, or Hoff, in *Geography*, formerly imperial, a town of Germany, in the principality of Culmbach, on the Saale, by which it is divided into the Old and New Town. It has three fauxbourgs, four churches, an academy, and a woollen manufacture. In its environs are quarries of marble, red, black, and grey, ſome of the latter being marked with red ſpots like blood; 46 miles N.E. of Bamberg. N. lat. 50° 18′. E. long. 12° 30′.—Alſo, a town of Norway, in the dioceſe of Aggerhuus; 36 miles N. of Berga.

HOFF, a town of Moravia, in the circle of Olmutz; 18 miles N.E. of Olmutz. N. lat. 49° 46′. E. long. 17° 27′.—Alſo, a town of Pruſſia, in the province of Natangen; four miles S. of Landſberg.

HOFFHEIN, a town of the duchy of Wurzburg; 36 miles N.E. of Wurzburg.

HOFFKIRCHEN, a town of Auſtria; 10 miles S. of Aigen.

HOFFLITZ, a town of Bohemia, in the circle of Leitmeritz; five miles S.E. of Tetſchen.

HOFFMAN, in *Biography*, an excellent compoſer of inſtrumental muſic, particularly ſymphonies, was maeſtro di cappella in the cathedral of St. Stephen at Vienna in 1772, and a maſter much eſteemed at that time in the imperial capital.

HOFFMANISTS, in *Eccleſiaſtical Hiſtory*, denote thoſe who eſpouſed the ſentiments of Daniel Hoffmann, profeſſor of the univerſity of Helmſtadt, who, from the year 1598, maintained that philoſophy was a mortal enemy to religion; and that what was true in philoſophy was falſe in theology. Theſe abſurd and pernicious tenets occaſioned a warm and extenſive controverſy; at length Hoffmann was compelled by Julius, duke of Brunſwick, to retract his invectives againſt philoſophy, and to acknowledge, in the moſt open manner, the harmony and union of ſound philoſophy with true and genuine theology.

HOFFMANN, Gaspar, a phyſician of ſome eminence about the beginning of the ſeventeenth century, was a native of Gotha, in Thuringia, where he was born in November, 1572. By the aſſiſtance of a friend he was ſupported during his reſidence at the moſt celebrated univerſities of thoſe times, and graduated at Baſle in the year 1605. In 1607, he was appointed profeſſor of the theory of medicine at Altdorf, the duties of which, and of other profeſſorſhips, he continued to fulfil, with credit and reputation, until his death, which occurred in November, 1648. Gaſpar Hoffmann was generally conſidered by his contemporaries as a man of great erudition, and was author of numerous publications, in which he ſhewed a bigotted attachment to the doctrines of the ancients, eſpecially of Ariſtotle. His works are not ſufficiently intereſting, however, at preſent to require an enumeration of their titles. Haller conſidered much of his diſplay of knowledge as ſpurious; and affirms that, as he wrote upon anatomical ſubjects without having touched a knife, ſo he treated copiouſly on the practice of phyſic, without having viſited the ſick. Eloy. Dict. Hiſt. Haller Bibl. Med. Pract.

HOFFMANN, Maurice, a phyſician, anatomiſt, and botaniſt, was born at Furſtemwald, a ſmall town in the Middle Mark of Brandenburg, in September, 1622. During his early youth, his native country was deſolated by war and peſtilence, which compelled his parents to fly from place to place, and interrupted the education of Maurice, whoſe acquirements did not go beyond the art of writing. Having loſt his father and mother at the age of ſixteen, his ardour for knowledge led him to Altdorf, in 1638, where a maternal uncle was profeſſor of medicine. Here he made a moſt rapid progreſs in philoſophy and the learned languages, and commenced the ſtudy of phyſic. In 1641 he repaired to the then celebrated univerſity of Padua, where he was particularly devoted to the ſtudy of anatomy and botany. In the former of theſe ſciences he is entitled to the name of a diſcoverer, if the relation of Bartholin be true; that, while yet a ſtudent, he was amuſing himſelf with the diſſection of a turkey, and diſcovered the pancreatic duct, which he ſhewed to the anatomiſt Wirſung, with whom he lodged at Padua, and who afterwards found it in the human ſubject, and gave it his own name. After a reſidence of three years in Italy, Hoffmann returned to Altdorf, where he received the doctor's cap in April, 1645, and was ſoon appointed to a profeſſorſhip; for in the year 1648 he obtained the extraordinary chair of anatomy and ſurgery; and in the following year he ſucceeded Gaſpar Hoffmann as ordinary profeſſor of theſe departments. He likewiſe was appointed ſucceſſor to Lewis Jungerman, in the botanical chair, in 1653. He urged the ſtrongeſt ſuggeſtions relative to the neceſſity of a garden for the culture and demonſtration of plants, and was not leſs ſtrenuous in his repreſentations in favour of the eſtabliſhment of a laboratory and an anatomical theatre: and it was to his exertions that the univerſity was indebted for theſe valuable acquiſitions. In addition to his academical occupations, he purſued the practice of medicine with conſiderable aſſiduity; and he obtained ſuch eminence as a practitioner, that ſeveral of the German princes honoured him with the title of their phyſician. In a word, his induſtry in the cloſet, his ſkill and humanity at the bed-ſide of the ſick, his eloquence in the chair, and his various ſocial qualities, rendered him worthy of the general eſtimation in which he was held. He died of apoplexy, on the 20th of April, 1698, in the ſixty-ſeventh year of his age. He had been three times married, and had eighteen children.

Maurice Hoffmann wrote ſeveral diſſertations on anatomical topics, but his principal works were botanical. On this ſubject he publiſhed "Floræ Altdorffinæ Deliciæ Hortenſes," 1660, or a catalogue of the plants in the botanical garden; to which ſeveral appendices were afterwards printed, containing the additional plants, which were introduced in ſubſequent years. He likewiſe printed "Floræ Altdorffinæ Deliciæ Sylveſtres," 1660, being a catalogue of the wild plants, growing ſpontaneouſly in the neighbourhood of Altdorf: and "Deſcriptio Montis Mauritii in agro Leimburgenſium, &c." 1694, being a catalogue of the plants of Mount Maurice and the adjacent countries. Eloy. Dict.

Hoffmann, John Maurice, ſon of the preceding, was born at Altdorf, in October, 1653. He acquired a knowledge of the learned languages at Herſpruck, and ſtudied medicine and philoſophy under his father, and ſubſequently at Frankfort upon the Oder, and at Padua. After a reſidence of two years in the laſt mentioned univerſity, he made the tour of Italy, and returned to his native city, where he was admitted to the degree of M. D. in 1675. His talents and acquirements obtained for him ſucceſſively the higheſt honours and offices in the faculty at Altdorf. He began with the profeſſorſhip extraordinary of anatomy, to which he was appointed in 1677, and in 1681 he became ordinary profeſſor of the ſame branch. In the following year, the profeſſorſhip of chemiſtry was given to him, and he read ſeveral courſes in the laboratory, with which his father's ſolicitations had enriched the univerſity. He afterwards undertook the profeſſorſhip of botany. In 1709, he reſigned the anatomical chair, and confined himſelf to the profeſſorſhip of the practice of medicine, which he retained as long as he remained at Altdorf. But Hoffmann was not more diſtinguiſhed by the able performance of his academic duties, than by the ſucceſs of his practice; ſo that he was ſought for by perſons of the higheſt rank, and eſpecially by the princes of the houſe of Anſpach. He was appointed phyſician to the marquis of Anſpach in 1695, and accompanied him in a journey to Italy; and after the death of this patron, in 1703, he found the ſame kindneſs from his ſucceſſor, who preſſed him earneſtly to remove to Anſpach. But it was not until the year 1713, that Hoffmann could be prevailed upon to quit his academic duties: in that year he fixed himſelf at Anſpach, where he died in October, 1727, at the age of ſeventy-four. He left ſeveral works of repute: *viz.* two diſſertations on anatomy and phyſiology; one on what has ſince been called morbid anatomy, entitled "Diſquiſitio corporis humani Anatomico-Pathologica;" ibid. 1713. "Acta Laboratorii chemici Altdorffini," 1719. "Syntagma Pathologico-therapeuticum," 1728, in two vols. 4to. and "Sciagraphia Inſtitutionum Medicarum," a poſthumous publication. He alſo continued his father's "Floræ Altdorffinæ." See Hutchinſon Biographia Medica. Eloy. Dict. Hiſt. de la Médecine.

Hoffmann, Frederic, the moſt eminent phyſician of his name, was born at Halle, in Saxony, on the 19th of February, 1660. He received his early education in his native town, and had made great progreſs in philoſophy and the mathematics, when, at the age of fifteen, he loſt his father and mother during the prevalence of an epidemic diſeaſe. In 1679 he commenced the ſtudy of medicine at Jena, and in the following year attended the chemical lectures of Gaſpar Cramer, at Erfurth; and, on his return to Jena, received the degree of M. D. in February 1681. In the year 1682 he publiſhed an excellent tract "De Cinnabari Antimonii," which gained him great applauſe, and a crowd of pupils to a courſe of chemical lectures, which he delivered there. At the concluſion of this courſe, he was induced to viſit Minden, in Weſtphalia, on the invitation of a relation, and practiſed his profeſſion there for two years with conſiderable ſucceſs. He then travelled into Holland and thence to England, where he was received with diſtinction by men of ſcience, and particularly by Paul Herman, the botaniſt in the former, and Robert Boyle in the latter. On his return to Minden, in 1685, he was made phyſician to the garriſon there, and in the following year was honoured by Frederic William, elector of Brandenburg, with the appointments of phyſician to his own perſon, and to the whole principality of Minden. Nevertheleſs he quitted that city in 1688, in conſequence of an invitation, which his riſing reputation procured him, to ſettle at Halberſtadt, in Lower Saxony, as public phyſician. His fame continued to extend, and he publiſhed a treatiſe "De inſufficientia acidi et viſcidi," by which he overthrew the ſyſtem of Cornelius Bontekœ. In 1689 he married the only daughter of Andrew Herſtel, an eminent apothecary, with whom he had lived forty-eight years in perfect union, when ſhe died. About this time, Frederic III., afterwards firſt king of Pruſſia, founded the univerſity of Halle; and in 1693 Hoffmann was appointed primary profeſſor of medicine, and compoſed the ſtatutes of that inſtitution. As a colleague in the medical profeſſorſhip he recommended the celebrated Stahl, who proved the great rival of his fame as a teacher. He was moſt active in the exerciſe of his profeſſional duties; and while he introduced a ſpirit of free and enlarged inquiry into the new univerſity, he extended its fame and elevated its character, by the eloquence and profound information diſplayed in his lectures. At the ſame time his own reputation was ſpread abroad by the learned works which he publiſhed, and procured him admiſſion into the ſcientific ſocieties at Berlin, Peterſburgh, and London, as well as the honour of being conſulted by perſons of the higheſt rank. He was called upon to viſit many of the German courts in his capacity of phyſician, and received honours from ſeveral princes; from whom ſome ſay that he received ample remuneration in proportion to the rank of his patients; while others have aſſerted that he took no fees, but contented himſelf with his ſtipends. Haller aſſerts that he acquired great wealth by various chemical noſtrums which he vended. In 1704 he accompanied ſome of the Pruſſian miniſters to the Caroline warm baths in Bohemia, on which occaſion he examined their nature, and publiſhed a diſſertation concerning them. On ſubſequent viſits, he became acquainted with the Sedlitz purging waters, which he firſt introduced to public notice, having publiſhed a treatiſe on them in 1717: and he afterwards extended his enquiries to the other mineral waters of Germany. Among other illuſtrious patients, who applied to him in theſe excurſions, were the emperor Charles VI. and his empreſs. In the year 1708, he was called to Berlin to take care of the declining health of Frederic, and was honoured with the titles of archiater and aulic counſellor, together with a liberal ſalary. After three years reſidence at this court he returned to Halle, and gladly reſumed his academical functions. He continued alſo to labour in the compoſition of his writings; and in 1718, at the age of 60, he began the publication of his "Medicina Rationalis Syſtematica," which was received with great applauſe by the faculty in various parts of Europe, and the completion of which occupied him nearly twenty years. He likewiſe publiſhed two volumes of "Conſultations," in which he diſtributed into three "centuries," the moſt remarkable caſes which had occurred to him; and alſo "Obſervationum Phyſico-Chemicarum ſelectionem Libri tres," 1722. In 1727 he attended the prince of Schwartzemburg through a dangerous diſeaſe; in recompence for which his noble patient created him count palatine. He quitted Halle in 1734, in order to pay a ſhort viſit to his daughter and ſon-in-law at Berlin, which, however, was made longer than he intended; for he was detained five months by the king of

Pruſſia, Frederic William, in order to attend him during a dangerous illneſs, which had attacked him in his camp on the Rhine. During this attendance Hoffmann is ſaid, by dignified remonſtrance, to have ſecured himſelf againſt the brutal rudeneſs with which the monarch treated his other phyſicians ; and he was ultimately treated with great honour, being elevated to the rank of privy counſellor, and preſented with a portrait of the king, ſet in diamonds. His majeſty likewiſe procured the portrait of Hoffmann, from the ſame painter, which was placed in the palace of Monbijou : and to Hoffmann's only ſon he preſented a profeſſorſhip of medicine in the univerſity of Halle, with the title of his conſulting phyſician. Hoffmann declined a preſſing invitation to ſettle at Berlin, on account of his advanced age, and returned to Halle in April 1735. The illneſs and death of his beloved wife, in 1737, turned his thoughts to the conſolations of religion, and he drew up in Latin a ſummary of Chriſtian doctrine, which, at the king's deſire, was tranſlated into German. He continued to perform his academical duties until the year 1742, when he died in the month of November, aged eighty-two.

Frederick Hoffmann was an induſtrious and copious writer. Haller has occupied thirty-eight quarto pages in the enumeration of his works in detail. The principal of theſe were collected, during the life of the author, by two Geneveſe bookſellers, and publiſhed with his approbation, and with a preface from his pen, in 1740, in ſix volumes folio. It was re-printed by the ſame bookſellers, the frères de Tournes, in 1748 ; and in the following year, having raked together every thing which his pen had touched, they publiſhed a ſupplement in three additional volumes folio, which was alſo re-printed in 1753-4. The writings of Hoffmann contain a great maſs of practical matter of conſiderable value, partly compiled from preceding writers, and partly the reſult of his own obſervation ; but they contain alſo many trifling remarks, and not a little hypothetical conjecture, which was indeed a common fault of the times ; and in the detail there is conſiderable prolixity and repetition. As a theoriſt his ſuggeſtions were of great value, and contributed to introduce that revolution in the ſcience of pathology, which ſubſequent obſervation has extended and confirmed. His doctrine of *atony* and *ſpaſm* in the living ſolid, by which he referred all internal diſorders to ſome " preternatural affection of the nervous ſyſtem," rather than to the morbid derangements and qualities of the fluids, firſt turned the attention of phyſicians from the mere mechanical and chemical operations of the animal body to thoſe of the primary moving powers of the living ſyſtem. To Hoffmann Dr. Cullen acknowledges the obligations we are under for having firſt put us into the proper train of inveſtigation ; although he himſelf did not apply his fundamental doctrine ſo extenſively as he might have done, and every where mixed with it a humoral pathology as incorrect and hypothetical as any other. Hoffmann purſued the ſtudy of practical chemiſtry with conſiderable ardour, and improved the department of pharmacy, by the addition of ſome mineral preparations ; but, on the whole, and eſpecially in his latter years, his practice was cautious and even inert, and he truſted much to vegetable ſimples. See Eloy. Dict. Hiſt. Vit. Fr. Hoffmanni à J. H. Schultze, and his Epiſt. to the king of Pruſſia, both prefixed to the Geneva edition of his works. Gen. Biography. Preface to Cullen's Firſt Lines.

HOFFMANNIA, in *Botany*, ſo called by Swartz, in honour of ſeveral able German botaniſts of the name of Hoffmann. Mauritius, and his ſon John George Henry, were ſucceſſively profeſſors at Altdorf. The former died in 1698, the latter in 1727. They publiſhed catalogues of the Altdorf garden, and of the wild plants of that neighbourhood. Frederick Hoffmann, profeſſor at Halle, who died in 1742, aged 82, publiſhed various medico-botanical diſſertations on Sugar, Cloves, Balſam of Peru, Yarrow, Manna, &c. and in one of them recommended the leaves of *Veronica officinalis*, as preferable to the tea of China ; a doctrine which has made as little progreſs in the world, as ſome others better founded in truth. Profeſſor George Francis Hoffmann of Göttingen is particularly diſtinguiſhed by his deſcriptive work on *Salices*, and his ſplendid *Plantæ Lichenoſæ*, both in folio ; and has alſo favoured the world with ſeveral other botanical writings. He was born in 1760, and is one of the moſt eminent cryptogamic botaniſts of the preſent day.—Swartz. Prodr. 2. Ind. Occ. v. 1. 241. t. 5. Schreb. 788. Willd. Sp. Pl. v. 1. 613. Mart. Mill. Dict. v. 2. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Stellatæ*, Linn. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, ſmall, of one leaf, with four erect acute teeth. *Cor.* of one petal, ſalver-ſhaped ; tube extremely ſhort ; limb in four deep, lanceolate, ſpreading ſegments. *Stam.* Filaments none ; anthers four, attached to the baſe of the tube, linear awl-ſhaped, erect, preſſed cloſe to the ſtyle. *Piſt.* Germen inferior, oblong, quadrangular ; ſtyle awl-ſhaped, the length of the ſtamens ; ſtigma obtuſe, downy, ſcarcely notched. *Peric.* Capſule oblong, bluntly quadrangular, pulpy, crowned with the calyx, of two cells and two valves. *Seeds* numerous, roundiſh, affixed to an ovate diſtinct receptacle in each cell.

Eſſ. Ch. Calyx four-toothed. Corolla ſalver-ſhaped, in four deep ſegments. Filaments none ; capſule pulpy, with two cells, two valves, and many ſeeds affixed to diſtinct ovate receptacles.

Obſ. The receptacles, as deſcribed by Dr. Swartz, evince the propriety of terming this fruit a pulpy capſule, and not a berry, the latter properly requiring the ſeeds to be imbedded in pulp, without any diſtinct receptacles, much leſs valves.

1. H. *pedunculata*. Sw. Ind. Occ. v. 1. 242. The only ſpecies. Found by Swartz in rather moiſt ſhady places on the high mountains of Jamaica. The *ſtem* is herbaceous, two or three feet long, branched, ſmooth, rather ſhrubby at the baſe ; its branches round and hairy. *Leaves* ſtalked, oppoſite, croſſing each other in pairs, ovate, pointed, entire ; wedge-ſhaped at the baſe ; above ribbed, ſhining, rough with elevated points ; veiny, pale and hairy beneath. *Stipulas* oppoſite, very ſhort, acute, thick and hairy, ſtanding between the *footſtalks*. *Flower-ſtalks* axillary, oppoſite, ſolitary, longer than the footſtalks, many-flowered, lax, hairy. *Calyx* coloured. *Corolla* yellowiſh at the points, ſtriated with red at the bottoms of the ſegments. *Anthers* yellow, cohering as in the nightſhade, *Solanum*. *Berry* ſcarlet when ripe.

HOFFMARKT, in *Geography*, a town of Auſtria, ſituated on the river March ; 26 miles E.N.E. of Vienna.

HOFFMARKT, *Furth*, a town of Germany, in the marggraviate of Anſpach, on the Rednitz, peopled with mechanics and artiſans ; ſuch eſpecially as cannot obtain the freedom of Nuremberg. The Jews are numerous, and have a ſchool and printing-houſe ; five miles N.W. of Nuremberg.

HOFFWA, a town of Sweden, in Weſt Gothland ; 80 miles N. E. of Uddevalla.

HOFHAIMER, PAUL, in *Biography*, publiſhed at Nuremberg, in 1539, a tract in Latin entitled " Harmoniæ Poeticæ," the ſecond part of which contains a notation of all the rhythms and meaſures of the feet of Latin verſe. This tract is among Anthony Wood's printed books, in the Aſhmol. Muſeum. Paul Hofhaimer is celebrated by Luſcinius not only as an admirable performer on the organ, on whom the emperor Maximilian conferred great honours, but as a compoſer of the very firſt claſs, whoſe productions, which were not only learned and correct, but florid and pleaſing, had remained unrivalled during thirty years.

HOFMAN, Euchorus, publiſhed, in 1582, at Stralſund, where he was corrector of the public ſchool, a treatiſe on the tones or modes of the church, "Doctrina de Tonis, ſeu Modis Muſicis." This author, who is a follower of Glarianus, pretends that "the ſcience of the modes, or *canto fermo*, which is the moſt excellent part of muſic, is but little underſtood by the moderns; but he draws his information from muſicians of the higheſt authority."

HOFMANSTORP, in *Geography*, a town of Sweden, in Smaland; 12 miles S.E. of Wexio.

HOG, a town of Sweden, in the province of Helſingland. —Alſo, a ſmall iſland in Pamlico ſound, near the coaſt of North Carolina. N. lat. 34° 56'. W. long. 76° 36'.—Alſo, a ſmall iſland in the Atlantic, near the coaſt of Virginia. N. lat. 37° 30'. W. long. 75° 42'.—Alſo, an iſland on the E. ſide of lake Champlain, in Franklin county, Vermont; nine miles long, and generally about three miles broad.—Alſo, an iſland in Narraganſet bay, Rhode iſland, about two miles in circumference; two miles from Briſtol.—Alſo, an iſland below Peach iſland, in Upper Canada, ſituated in the ſtrait of Detroit, where it opens into lake St. Clair; containing about 300 acres of land fit for tillage, and a large quantity of marſh or meadow land. It has ſome wood; the land is low, but fit for paſturage, well improved, and contains in all about 1700 ſtatute acres.—Alſo, one of the ſmaller Shetland iſlands, near the E. coaſt of Mainland. N. lat. 60° 30'. W. long. 1° 12'.—Alſo, a ſmall iſland in the Eaſt Indian ſea, near the E. coaſt of Palawan. N. lat. 10° 18'. E. long. 119° 36'.—Alſo, an iſland in the Eaſt Indian ſea, 40 miles long and ſix broad; 60 miles W. of Sumatra. N. lat. 2° 30'. E. long. 95° 50'.—Alſo, an iſland in the Eaſt Indian ſea, about 20 miles in circumference. S. lat. 7° 5'. E. long. 114° 55'.—Alſo, an iſland in the Eaſt Indian ſea, 15 miles long, and ſix broad, near the W. coaſt of Saleyer. S. lat. 6° 12'. E. long. 120° 15'.

Hog, *Cape*, a mountainous headland on the coaſt of Syria, forming the S. point of the bay of Alexandretta, anciently called the "Rhoſius." N. lat. 36° 27'. E. long. 38° 8'.

Hog *Iſlands*, a cluſter of ſmall iſlands ſituated near the coaſt of the county of Kerry, between Ballinaſkelig's bay, and the entrance of Kenmare river, within three or four miles of Hog's Head. There is alſo a ſingle iſland called Hog iſland in the river Shannon, near its mouth.

Hog's *Head*, a cape of Ireland, on the S.W. coaſt, forming the eaſtern boundary of Ballinaſkelig bay, in the county of Kerry. N. lat. 51° 44'. W. long. 10° 8'.

Hog, in the *Linnæan Syſtem of Zoology*. See Sus.

The common hog, or *ſus ſcrofa* of Linnæus, is covered with briſtles. In a wild ſtate it is of a dark brinded colour, and under the briſtles there is a ſoft curled hair; the ears are ſhort and a little rounded. In its tame ſtate, the ears are long, ſharp-pointed, and flouching; the colour is generally white, ſometimes mingled with other colours. The hog, in its wild ſtate, is found in moſt parts of Europe, except the Britiſh iſles and the countries north of the Baltic; in Aſia, from Syria to the borders of the lake Baikal; in Africa, on the coaſt of Barbary; and in the foreſts of South America.

Tame hogs are found univerſally, except in the frigid zone and Kamtſchatka, and ſuch places where the cold is very ſevere. The Chineſe hog is only a variety of the common hog; its belly hangs almoſt to the ground, its legs are ſhort, its tail reaches to the heels, and the body is generally bare: it is a much cleaner animal than ours. Hogs are ſtupid and voracious animals; inſomuch that they will eat their own offspring, and devour even infants; but it is obſerved, that the hog is not indiſcriminate in the choice of its food; for it has been found to eat 72 ſpecies of vegetables, and to reject 171. In America it clears the country of rattle-ſnakes, which it eats with ſafety. Hogs cannot bear exceſſive cold, and are very reſtleſs in high winds.

There are few animals that are uſeful in a greater variety of ways than hogs. They are extremely prolific; their fleſh is agreeable and wholeſome food to thoſe who uſe much exerciſe; and as it takes ſalt better than any other kind, it is of great importance to a commercial nation. Hogs furniſh *brawn*, and *lard*, and *briſtles*. (See each article.) In Minorca, the aſs and the hog are yoked together to plough the land; and the hog has been applied to the ſame uſe in our own iſland, *viz.* in that part of Murray which lies between the Spey and Elgin. Pennant. See Boar.

Theſe animals are very profitable to the owner in different points of points of view, eſpecially on ſome particular kinds of farms, as thoſe of the arable and dairy deſcriptions. Indeed, on moſt ſorts, a few animals of this kind may be kept to great convenience and profit, as preventing the neceſſary waſte of different refuſe materials of the food kind, which can only be converted to ſuch uſes. Theſe animals are alſo capable of being kept to great profit in different deſcriptions of large manufactories where the conſumption of grain is extenſive; as in thoſe of brewing, diſtilling, and the making of ſtarch, &c. The breed of hogs ſhould be conſtantly well ſuited to the nature of the farm, and the extent of the keep which is capable of being provided for them, otherwiſe there may often be conſiderable loſs ſuſtained. The cloſe, compact, ſhort-legged breeds, which have much diſpoſition to take on fleſh, are, in general, to be preferred. But where the keep is good and abundant, breeds which attain a much larger ſize may ſometimes be more beneficial and proper. See *Live* Stock and Swine.

Hogs are apt to dig up the ground and to break fences; but this may be prevented, by putting rings in their noſes, and yokes about their necks. Leiceſterſhire, Northamptonſhire, and Hampſhire, are famous for theſe animals, which ſeems owing to their being clayey countries, and that more peas and beans are ſown there than in other places. The wild kind never grow ſo large as the tame, but they are much better taſted. The keepers of hogs ſhould always chuſe ſuch boars for the purpoſe of breeding as are long-bodied, and have deep bellies and ſides, ſhort noſes, thick thighs, ſhort legs, high claws, a thick neck, and a thin chine, well ſet with large briſtles. It is not proper to keep too many breeding ſows; for they will produce ſo many young at a time, and this three times a year, that they will not find food enough. They uſually bring thirteen or fourteen young ones in a litter, ſometimes more, but they can bring up no more than they have teats to ſuckle. Young ſhoots, as they are called, that is, ſwine of three quarters of a year old, are beſt for pork, and thoſe of a year and a half for bacon. The male pigs that are reared ſhould be gelt, and the ſows ſpayed; and for this purpoſe, thoſe which are pigged in the ſpring are the beſt. Moiſt and ſedgy grounds are good for ſwine, for they eat the roots of many of the plants that grow there; and the fruit of the beech, cheſnut, and hedge-buſhes, fatten them well, and make their fleſh much better taſted than when bred entirely in the ſtye.

Mr. Young obſerves, that hogs may be kept in ſummer, with great advantage to the farmer, in clover fields; and that lucern is ſuperior to clover for this purpoſe, and that ſaintfoin is very good; but that burnet is very bad. In winter they may be well maintained with carrots, parſnips, beets, and potatoes. The dairy ſhould be appropriated to rearing pigs and feeding ſows that have young. It appears, from other experiments of this writer on the fattening quality of ſeveral ſorts of food for hogs, that pollard alone is a cheaper food than peas alone; that boiled carrots are much the moſt profitable; that buck-wheat is more profitable than peas; that ſeveral kinds of food mixed are better than any given alone; that the meal of any one, or various kinds of grain, is better and more profitable than the whole grain mixed or alone; and that peas and barley are much ſweeter food than beans. The keeping of hogs in any city or market-town is indictable as a public nuiſance.

Hog *Ciſtern*, a contrivance prepared for the purpoſe of containing and preſerving the food employed in the keeping of hogs or ſwine. This ſort of baſon, or ciſtern, ſhould be formed in ſuch a ſituation as may be convenient for the kitchen, dairy, and hog-yard, being conſtructed in ſuch a manner as that there may be no loſs ſuſtained in its leaking and letting out the more liquid contents. Into this tub or ciſtern every thing ſhould be collected from the houſe, and other places, in order to be formed into waſh, or ſoup, for the ſtore pigs, and thereby no loſs be incurred. Where large ſtocks of hogs are kept, it is a matter of great convenience and utility to have different tubs or ciſterns of this nature, that the food may be properly prepared, and in ſufficient quantities for conſtant uſe, as by this means the food admits of being more ſuitably mixed and blended together.

The proper conſtruction of theſe ſorts of receptacles is a matter of very conſiderable importance; in Norfolk they are chiefly built with bricks and terrace, which is an expenſive method of forming them. Wooden veſſels are not by any means either durable or commodious, and thoſe of lead dangerous. Bricks laid in clay are ſuggeſted as perfectly water-tight, eſpecially when backed by a coat of the ſame ſubſtance. In forming theſe ciſterns, pits or cavities of ſuitable dimenſions ſhould be dug out, as of five or ſix feet in length, and four or five in breadth, having the depths of about five feet. The whole of the bottom of the cavity ſhould then be well bedded with good clay, well moiſtened and rammed down, ſmoothing the ſurface over neatly with a trowel. Upon this flooring three courſes of bricks, laid in mortar made with the beſt clay, ſhould be placed in ſuch a way as that the joints of one courſe may fall in the middle of the bricks of the courſe under it, the whole being laid lengthways, and not croſſed in the uſual method. The ſides muſt be carried up half a brick thick, which is a brick in width, being laid in the mortar of good clay; the vacancy left between the brick-work, and the ſides of the cavities being firmly rammed with moiſt clay, ſo as to combine the bricks as much as poſſible with the clay and the ſides of the pits, forming them into a ſort of ſolid body. The brick and clay-work ſhould be carried up equally together, beating back again ſuch bricks as may have been forced forward in the ramming of the clay, leaving the ſurface in the ciſtern quite even and regular. As, when brought up level with the ſurface of the ground, ciſterns of this nature, of five feet and a half by four, uſually meaſure about three feet in length, and two and a half in depth, the ſeam or layer of clay on the bottoms and ſides muſt be about four inches in thickneſs. By way of affording a good covering to ciſterns of this kind above the ground, a ſort of ſlanting ſhed ſhould be conſtructed over them by building ſlight brick-walls on each ſide of them to the height of three or more feet, with a gable raiſed at one end, the other being left open as a door, and the top cloſed by a roof and tiles. This method of covering ſuch reſervoirs is far ſuperior to thoſe merely having flaps, or other ſimilar contrivances.

Hog's *Fennel*, in *Botany*. See PEUCEDANUM.

Hog, *Hedge*. See ERINACEUS.

Hog, *Sea Hedge*. See ECHINODERMA, CENTRONIA, and *Sea* URCHIN.

Hog, *Hairs of*, in *Agriculture*, the ſtiff briſtly ſort of hair that is taken off from the body of hogs when they are killed, by means of ſcalding and ſcraping. This is a ſubſtance, where it can be collected in ſufficient quantity, that may be made uſe of with advantage as a manure. It is capable of being occaſionally purchaſed in the London markets at about nine or ten ſhillings the quarter, which is a ten buſhel ſack ſtuffed quite full; and is applied to the land in ſuch a way, as to be turned in juſt before the crops are ſown. In this method it is found to anſwer perfectly in ſoils of the more light deſcription. Seal hair has likewiſe been found capable of being employed in the ſame mode with equal ſucceſs.

Hog *Manure*, the name of that ſort which is produced by hogs in the ſties, yards, and other places where they are kept and confined. This is found, by experience, to be a very powerful and efficacious ſort of material, being conſidered by ſome as nearly equal to that of the horſe. It has, however, been ſuggeſted as an objection to it by ſome, that weeds are more liable to riſe after the application of it, than that of ſome other kinds of manure.

The farmers who uſe the dung of hogs for their lands, generally take care to ſave it by well paving the ſties, and increaſe the quantity by throwing in bean-ſtalks, ſtubble, and many other things of a like kind; and, by good management of this kind, many farmers have procured fifty or ſixty load of excellent manure a-year out of a ſmall ſtye. The very beſt way of uſing this dung is to mix it with horſe-dung; and, for this reaſon, it is beſt to have the ſtye near the ſtable, that the two cleanſings may be mixed in one heap, and uſed together.

They have, in many parts of Staffordſhire, a poor, light, ſhallow land, on which they ſow a kind of white pea. The land is neither able to bear this, nor any thing elſe, to their advantage, for reaping. But when the peas are ripe, they turn in as many hogs as the quantity of peas will fatten, ſuffering them to live at large, and remain there day and night; and, in conſequence of this, the land will produce good crops of hay for ſeveral years afterwards, or, if too poor for that, it will, at the worſt, raiſe graſs enough to make it a good paſture-ground. See DUNG and MANURE.

Hog-*plum*, in *Botany*. See SPONDIAS.

Hog-*ſheep*, a term often applied to the male or wedder of one year old, as from the time of weaning to that of its being firſt ſhorn.

Hog-*ſteer*, among *Hunters*, a wild boar of three years old. See BOAR.

Hog-*ſty*, the name of a houſe or building conſtructed for the purpoſe of confining and keeping different kinds of hogs and ſwine. Much, eſpecially in the ſaving of labour, and the making of manure, as well as in the food and keeping of the animals, depends upon the ſties being formed in a convenient manner. They are uſually built in a very plain and ſimple method, the chief objects being conſidered thoſe of warm dry ſituations for the animals to lie in, with ſmall areas or yards before them, and proper troughs fitted up for holding their food. They are moſt commonly conſtructed with lean-to or ſhed-roofs, and have but ſeldom more than ſix or ſeven feet width, with height in the ſame proportion. In order to have them as convenient as poſſible, they ſhould be at no very great diſtance from the houſe and offices, being well placed for the kitchen and dairy, but as little connected with the other out-buildings as may be. Some have ſuggeſted the great propriety and advantage, in particular caſes, of having them connected in ſuch a manner with the ſcullery, as that the whole of the refuſe articles from it may be readily conveyed to them by means of pipes or other ſimilar contrivances.

Where they are at a diſtance they ſhould conſtantly be ſo ſituated as that the ſervants need not have occaſion to enter the farm yards in the buſineſs of feeding them.

Although it be the common notion that hogs are naturally filthy in their habits, there are probably very few domeſtic animals that are more pleaſed when they have clean comfortable beds, and certainly not any on which cleanlineſs has a more evident effect, ſo far as thriving, feeding, and fattening are concerned. With the view of keeping them perfectly dry at all periods, a ſlight, but ſufficient degree of inclination or ſlope outwards ſhould conſtantly be given to the floors of the ſties as well as thoſe of the areas or yards with which they are connected, and proper drains be conſtructed for conveying away any moiſture that may be preſent in them. The outſide yards ſhould alſo be a little raiſed above the ſurface of the ground, and the ſties ſomewhat elevated above the yards. It is neceſſary alſo that there ſhould be a number of diviſions, in order to keep the different kinds of hog ſtock ſeparate, as there ſhould never be too great a number kept together, it being found by experience that they thrive and fatten better where the numbers are ſmall, and as nearly as poſſible ſimilar in the ſizes. Suitable diviſions are conſequently to be formed for female hogs when with the boar; others for breeding ſwine, as well as for their farrowing in; and ſtill others for properly weaning the young pigs in, for keeping the ſtore pig ſtock in, and for fattening the hogs of proper ages in. Where the nature of the ſituations will admit of it, the areas or yards ſhould be pretty extenſive. And in caſes where it can be done, it is of vaſt advantage to have water conveyed through them, as it ſerves not only to keep them clean with greater eaſe and facility, but anſwers a variety of other beneficial intentions.

It has been ſuggeſted by a writer on rural economy, that all pig-ſties ſhould be provided with rubbing poſts. "Having occaſion to ſhift two hogs out of a ſty without one into an other with a poſt accidentally put up to ſupport the roof, he had a full opportunity of obſerving its uſe. The animals, when they went in, were dirty, with broken ragged coats, and dull heavy countenances. In a few days they cleared away their coats, cleaned their ſkins, and became ſleeky haired: the enjoyments of the poſt were diſcernible, even in their looks, in their livelineſs, and in their apparent contentment. It is not probable that any animal can thrive while afflicted with pain or uneaſineſs. Graziers ſuffer ſingle trees to grow, or put up dead poſts in the ground, for their cattle to rub themſelves againſt; yet it is probable a rubbing poſt has never been placed intentionally in a ſty; though perhaps, for a two-fold reaſon, rubbing is moſt requiſite to ſwine."

In the conſtruction of hog-ſties, it is difficult to point out any plan that can be generally had recourſe to, as they muſt conſtantly depend upon the nature of the place and various other circumſtances of a local kind. It has, however, been lately ſuggeſted, that pig-ſties that are of conſiderable extent, ſhould conſtantly be in the form of a circle, or they muſt ſuſtain great loſs in point of convenience. In which caſe the centre ſhould contain the boiling or ſteaming houſe, with a granary for corn, meal, bran, and other ſimilar articles; having a range of ciſterns in diviſions around it, for the reception of the matters from the copper or ſteaming apparatus, as well as by pipes from the kitchen, dairy, and other places. Around theſe there ſhould be a path, and beyond it the fence, which may be a wall or pailing; in which the troughs with hanging lids ſhould be fixed, for ſupplying the food directly from the ciſterns on one ſide, and for the hogs feeding at on the other: next to this there ſhould be a range of yards, and another of low ſheds beyond it, and, laſtly, the receptacle for the dung. The pies or potatoe ſtores ſhould at one end point nearly to the entrance, and the water ſhould be raiſed to the coppers and ciſterns at once by means of a proper pump; there being a trough or ſome other conveyance from the dairy to the ciſterns for the milk, whey, and other liquid matters. This ſort of arrangement, it is ſuppoſed, will be extremely convenient and beneficial, while, at the ſame time, the expence need not be heavy. The ataching of a certain extent of graſs land, or that of ſown graſſes, in proper diviſions, into which the hogs may be capable of being turned as it may be found neceſſary, is, it is hinted, a matter of vaſt utility, where the nature of the ſituation will admit of its being done. Where there is not a proper and conveniently formed pig apparatus, little idea can be had of its advantage in the making of manure. Yet this alone, it is conceived, is an object that would juſtify any good farmer in going to a certain expence in attaining ſo profitable a portion of what ſhould conſtitute his farm-yard ſyſtem. It is ſtated as lamentable to ſee in nine-tenths of the farmeries of the kingdom, ſo many parts of the proper piggery ſcattered and unconnected in ſuch a way as to prevent convenience, multiply labour, and retard the forming of plentiful ſupplies of valuable manure. The building of a hoggery, ſomewhat though not exactly upon this principle, was found to coſt, including the boiling houſe, copper, pond, ciſterns, ſhed, pailing, paving, and troughs, about 78*l.*, independent of the timber. By means of a yard of this deſcription, one man will be capable of managing three times as many hogs as would otherwiſe be the caſe. And where they are properly and completely littered, the quantity of excellent manure that is formed is very aſtoniſhing. The extent of 98 loads of very rich dung compoſt, valued on the ſpot at five ſhillings the load, has been found to be made by the number of about 80 or 90 fattening hogs, or a clear profit of 15 or 16*l.*, derived ſolely from that article; and it would be double that, if the littering was performed in a complete manner. Theſe ſtatements fully prove the prodigious importance of poſſeſſing ſuch conveniences in the fattening of great numbers of hogs, in the view of raiſing manure.

Suppoſing the whole of the expence, including every thing, in one of theſe ſties, to riſe to 100*l.* and the intereſt to be five pounds per annum; it is aſked, what compariſon there can be between the annual expence of five pounds, and the prodigious utility of having the power of conſtantly fattening with ſcarcely any expence of labour, any number of hogs that may be required? By means of ſuch conveniences the whole of the peas, beans, barley, buck-wheat, potatoes, parſnips, carrots, and other ſimilar ſorts of food that are capable, or can be produced on a farm, may be converted to the purpoſe of rearing, feeding, or fattening of hogs; by which the farmer has the means of improving his ground in the cheapeſt manner, and to the fulleſt extent.

At preſent, the expence of ſuch ſheds and yards would be nearly double the above ſum; and, where erected upon the moſt correct plan, ſtill conſiderably more. The general principle ſhould, however, be followed in ſties of much ſmaller dimenſions. In many caſes and circumſtances, other plans and forms may, however, be followed with great propriety and advantage, being contrived ſo as to ſuit the local nature of the different ſituations.

Hog-*trough*, a kind of box or other contrivance conſtructed for the purpoſe of containing the food of hogs until it be conſumed. There are various kinds of troughs of this nature, which are formed of different ſorts of materials under different circumſtances; but thoſe of wood and ſtone are by much the moſt uſual. From the circumſtance of hogs being liable to ſpill and waſte a conſiderable portion of their food by getting their feet into it, Mr. Bateſon has been induced to attempt the prevention of it, by having a rail or covering made to ſlope from the back to the fore part of the trough, which may be formed of any ſort of thin deal, juſt ſufficient room being left to admit the heads of the animals. Diviſions are likewiſe made croſſways of the troughs, in proportion to the number of the hogs, in order to prevent the ſtrongeſt from driving away ſuch as are weak. But theſe diviſions are not neceſſary to extend to the bottom of the troughs; they ſhould, however, riſe a little higher than the top, and are capable of being formed of portions of boards, which are about eight or ten inches in breadth. But another way of preventing them from waſting their food, it is conceived, would be to have ſhallow wooden troughs placed about a foot from the ground, having large deep troughs above them with open bottoms. The food is depoſited in the large-upper troughs, but at the ſame time no more is capable of paſſing down, than what reſts in the bottoms of the ſhallow troughs; conſequently, when that is conſumed, a freſh ſupply will continually take place from the large upper troughs.

However, for food of the more liquid kind, ſuch as milk, whey, and others of a ſimilar kind, there may, it is ſuppoſed, be a ſtone trough below, and ſpars or holes in the bottom of the ſhallow trough, to let the fluid matters paſs through. Theſe ſorts of troughs are capable of being made to ſerve two diviſions of the ſty at the ſame time, by having them fixed up between them. Where water can be conducted through the ſty in a ſmall ſtream, by means of an open ſort of ſpout, ſo that it may conveniently ſupply the animals, it will be found of very great advantage.

Hog-*weed*, in *Botany*. See Boerhavia.

Hog-*weed*, a name frequently applied provincially to knot-graſs.

Hog, on board of a *Ship*, is a ſort of flat ſcrubbing broom, formed by incloſing a number of ſhort twigs of birch or ſuch wood, between two pieces of plank faſtened together, and cutting off the ends of the twigs, and ſerving to ſcrape the filth from a ſhip's bottom, under water, particularly in the act of boot-topping. For this purpoſe they fit to this broom a long ſtaff with two ropes; one of which is uſed to thruſt the hog under the ſhip's bottom, and the other to guide and pull it up again, cloſe to the planks. This buſineſs is commonly performed in the ſhip's boat, which is confined as cloſe as poſſible to the veſſel's ſide during the operation, and ſhifted from one part of the ſide to another, till the whole is completed. Marine Dict.

Hogs' *Bones, Petrified*, in *Natural Hiſtory*. Writers on extraneous foſſils have mentioned but very few bones or teeth which they refer to the genus ſus or hog, and have preſerved little which is preciſe enough to entitle them to this claſſification. M. G. A. Cuvier, who gives a memoir on this ſubject, in the 14th vol. of the "Annales du Muſéum," of which a tranſlation may be ſeen in the Phil. Mag. vol. 35, p. 219, conſiders all the foſſil remains which can ſafely be referred to the genus ſus (whoſe characters, applicable to this enquiry, he gives) to belong to the peats and moſt modern of the alluvia of low grounds, or to be peat or recent foſſils.

HOGARTH, William, in *Biography*, one of thoſe few original and extraordinary characters whom it has pleaſed Providence occaſionally to bleſs the world with; to enlighten mankind, and to carry the arts and ſciences neceſſary for their comfort, pleaſure, and improvement, nearer to perfection. It cannot, indeed, be truly ſaid of Hogarth, that he improved the practice of the arts of painting and engraving which he profeſſed; but he merited the praiſe of having more powerfully exhibited their moral utility than any of his predeceſſors; and that in a new and till then unthought of mode, more generally felt and underſtood, being adapted to the feelings of all orders of men, as it aroſe from a cloſe obſervance of the actions and expreſſions common to all under the influence of the paſſions. Moved by the impulſe of genius rather than the tuition of man, he travelled in a path unexplored by any before him, and which yet remains cloſed to ſucceeding artiſts. Poſſeſſing, by early practice, the knowledge of the art of engraving, he was happily enabled to diſſeminate, by its means, the ingenious inventions and labours of his mind, in a manner more perfect than thoſe of other painters have been preſented to the world, or than probably ever again will be done, till another painter ſhall be his own engraver. Stimulated by the love of fame, and the deſire of many of his friends, Hogarth, towards the cloſe of his life, compoſed a ſhort hiſtory of himſelf, from whence we ſhall extract the moſt eſſential parts; and preſent our readers with ſome illuſtration of his works, his character, his pretenſions to public favour, and the reception he experienced.

His father's name was Richard, he was a man devoted to literature; but his pen, like that of many other authors, did not enable him to do more for his children than to give them education; and merely, as his ſon obſerved, put them in a way of ſhifting for themſelves. William, of whom we now treat, was born in London, in the pariſh of St. Bartholomew the Great, on the 10th of November, 1697. What will thoſe who hold the non-exiſtence of innate genius for peculiar arts, &c. reply to Hogarth's account of the ſenſations he experienced in his infancy? *viz.* "Having naturally a good eye and fondneſs for drawing, ſhows of all ſorts gave me uncommon pleaſure when a child, and mimickry was remarkable in me."—"An early acceſs to a neighbouring painter drew my attention from play, and I was at every poſſible opportunity employed in making drawings."—"My exerciſes, when at ſchool, were more remarkable for the ornaments which adorned them, than for the exerciſe itſelf; in the former, I ſoon found that blockheads with better memories could much ſurpaſs me, but for the latter I was particularly diſtinguiſhed."—"It was therefore very conformable to my own wiſhes that I was taken from ſchool and ſerved a long apprenticeſhip to a ſilver-plate engraver." This engraver was Mr. Ellis Gamble, of Cranbourn-alley.

"I ſoon found this buſineſs in every reſpect too limited. The paintings of St. Paul's cathedral and Greenwich hoſpital, then going on by ſir James Thornhill, ran in my head; and I determined that ſilver-plate engraving ſhould be followed no longer than neceſſity obliged me to it. Engraving on copper was, at twenty years of age, my utmoſt ambition. To attain this, it was neceſſary that I ſhould learn to draw objects ſomething like nature, inſtead of the monſters of heraldry." Animated by this deſire, he conſidered how he could, by the ſhorteſt way, obtain poſſeſſion of the knowledge he required; and ſpurning the regular mode of academical ſtudy, adopted a plan of his own. "Many reaſons," he ſays, "led me to wiſh that I could find the ſhorter path; fix forms and characters in my mind; and inſtead of copying lines, try and read the language of the art; and, if poſſible, find its grammar, by bringing into one form the various obſervations I had made, and then try how far I could combine them, and apply them to practice.

"Laying it down firſt, as an axiom, that he who could by any means acquire and retain in his memory perfect ideas of the ſubjects he meant to draw, would have as clear a knowledge of the figure as a man, who can write freely, hath of the twenty-four letters of the alphabet, and their infinite combinations (each of theſe being compoſed of lines); and would conſequently be an accurate deſigner:—

"I, therefore, endeavoured to habituate myſelf to the exerciſe of a ſort of technical memory, and by repeating in my own mind the parts of which objects were compoſed, I would by degrees combine and put them down in pencil. Thus, with all the drawbacks which reſulted from the circumſtances in which I was placed, I had one material advantage over my competitors, *viz.* the early habit I thus acquired of retaining in my mind's eye, without coldly copying it on the ſpot, whatever I intended to imitate.

"My pleaſures and my ſtudies thus going on hand in hand, the moſt ſtriking objects that preſented themſelves, either comic or tragic, made the ſtrongeſt impreſſions on my mind; but had I not ſedulouſly practiſed what I had thus acquired, I ſhould very ſoon have loſt the power of performing it."—"Inſtead of burthening the memory with muſty rules, or tiring the eyes with copying dry and damaged pictures, I have ever found ſtudying from nature the ſhorteſt and ſafeſt way of attaining knowledge in my art. By adopting this method, I found a redundancy of matter continually occurring. A choice of compoſition was the next thing to be conſidered, and my conſtitutional idleneſs naturally led me to the uſe of ſuch materials as I had previouſly collected; and to this I was further induced by thinking, that if properly combined, they might be made the moſt uſeful to ſociety in painting, although ſimilar ſubjects had often failed in writing and preaching."

In concurrence, therefore, with this reaſoning, Hogarth ſet about qualifying himſelf for the purſuit of his object immediately upon the expiration of his apprenticeſhip, which was about the year 1718; and began to engrave on copper for the bookſellers. This praiſe-worthy emulation wrought with him as it generally does with thoſe who dare to enter ſo ſelf-denying a courſe of exiſtence. He continued to live in induſtrious indigence for ſome time, whilſt thoſe who had the means of vending his early productions were growing rich by his labours.

It is ſaid of one of thoſe patrons of the youthful artiſt, that he very generouſly offered him half-a-crown a pound for a finiſhed plate; and at another time the ſame perſon offered to Mr. Major two plain pieces of copper for two engraved ones; with the *generous view* that the youth might not lack the means of exerting his ingenuity!!

Feeling the full weight of this kind of treatment, Hogarth reſolved upon publiſhing on his own account. But in this he had to encounter another enemy in the body of printſellers, who, upon his publiſhing his firſt plate of "The Taſte of the Town, or Burlington Gate," (in 1724,) ſoon procured copies of it, and ſold them at half the price; ſo that he was obliged to ſell the plate as their ſhops were the only places of ſale.

"Owing to theſe kinds of circumſtances, till I was near thirty years of age," he ſays, "I could do little more than barely maintain myſelf by engraving."

It is probable, that about the time of publiſhing the abovementioned print he commenced painter; as Mr. John Ireland ſtates, in his account of Hogarth, that he was in poſſeſſion of a ſet of pictures deſigned for the large plates he publiſhed from Butler's Hudibras in 1726. They are but indifferent in the promiſe they hold forth of their author, and are executed in ſomewhat of the ſtyle of Hemſkirk. From this time he was known as a painter, and employed in painting portraits, and ſmall pictures of family converſations, as they are called, or groups of family portraits.

In 1729, he married the only daughter of ſir James Thornhill, without the conſent of the knight her father; who probably regarded him as an inferior artiſt, and felt degraded by the union, till the deſigns for the Harlot's Progreſs were laid before him; ſatisfied then that his daughter had choſen a man of extraordinary merit, though poor in purſe, he became reconciled to the match, and lived till his death in terms of intimacy with his ſon-in-law, and was a conſtant and generous friend to him.

Hogarth proceeded with ſucceſs for ſome time in painting his portraits, "but feeling it a kind of drudgery, and as I could not act like ſome of my brethren, and make it a ſort of manufactory to be carried on by the help of back-ground and drapery painting, it was not ſufficiently profitable to pay the expences of my family. I therefore turned my thoughts to a ſtill more novel mode in painting and engraving modern moral ſubjects, a field not broken up in any country or any age.

"The reaſons which induced me to adopt this mode of deſigning were, that I thought both writers and painters had, in the hiſtorical ſtyle, totally overlooked that intermediate ſpecies of ſubjects which may be placed between the ſublime and groteſque. I therefore choſe to compoſe pictures on canvas, ſimilar to repreſentations on the ſtage: and farther hope that they will be tried by the ſame teſt and criticiſed by the ſame criterion.

"In theſe compoſitions, thoſe ſubjects that will both entertain and improve the mind bid fair to be of the greateſt public utility, and muſt, therefore, be entitled to rank in the higheſt claſs."—"I have endeavoured to treat my ſubject as a dramatic writer; my picture as my ſtage, and men and women my players; who, by means of certain actions and geſtures, are to exhibit *a dumb ſhow*.

"In purſuing my ſtudies, I made all poſſible uſe of the technical memory, which I have before deſcribed, by obſerving, and endeavouring to retain in my mind lineally, ſuch objects as beſt ſuited my purpoſe: ſo that, be where I would, while my eyes were open, I was continually at my ſtudies; and acquiring ſomething uſeful to my profeſſion. A redundancy of matter being by this means acquired, it is natural to ſuppoſe, that I introduced it into my works on every occaſion that I could.

"By this *idle* way of proceeding, I grew ſo profane as to admire nature beyond the firſt productions of art; and acknowledged I ſaw, or fancied, delicacies in the life ſo far ſurpaſſing the utmoſt efforts of imitation, that when I drew the compariſon in my mind, I could not help uttering blaſphemous expreſſions againſt the divinity of Raphael, Correggio, and Michael-Angelo. For this, though my brethren have moſt unmercifully abuſed me, I hope to be forgiven. I confeſs to have frequently ſaid, that I thought the ſtyle of painting which I had adopted, admitting that my powers were not equal to doing it, might, one time or other, come into better hands, and be made more entertaining, and more uſeful, than the eternal blazoning, and tedious repetition, of hackneyed beaten ſubjects, either from the ſcriptures, or the old ridiculous ſtories of heathen gods: as neither the religion of the one or the other requires promoting among Proteſtants, as it formerly did in Greece; and at a later period in Rome."

In language of this nature Hogarth was accuſed of vanity, and of enviouſly endeavouring to under-rate what he was unable to execute. And certainly with much juſtice the remarks appear to have been made; for, previouſly to his adopting the line of conduct in painting, which was ſo ſuitable to his peculiar genius, he attempted ſeveral pictures in the grand hiſtorical ſtyle, and in all failed moſt woefully. It is apparent that he at no time of his life underſtood the object or character of that ſpecies of art, and was, therefore, ill qualified to judge of its value. But probably he was urged to the ſtrong declarations which he indulged in, by ſeeing the ſucceſs of infamous dealers in bad copies, and continually hearing, as all painters are obliged to do, bad originals exalted beyond all bounds, becauſe they are ſuppoſed to be the productions of this or that man of genius; while, in fact, they may be the inferior labours of ſome mongrel imitator. What, however, but the extreme of vanity, could induce a man, ſo ill trained in art, to think of contending with Pouſſin and Correggio in hiſtory, and with Vandyke in portrait. He aſſerted himſelf equal to either in their way, and in both proved himſelf groſsly defective. In his own line and manner, and in that alone, diſtinct from every one, he was ſuper-excellent; conceiving his ſubjects with moſt conſummate intelligence, and executing them with appropriate character and ſtyle.

After ſome time he felt the effect of the remarks of his adverſaries (though he never acknowledged his incapacity), and almoſt entirely abandoned portraiture and ſerious hiſtory; and wiſely adhered to his judicious choice of ſubject and manner; for the adoption of which he felt ſuch powerful reaſons as are mentioned above.

He had, however, in the interim, favoured the world with various productions of that kind, which were then, and ſtill are, and probably for ever will be, highly eſteemed. In 1733 he publiſhed his firſt great work, "The Harlot's Progreſs;" and in 1735, it was followed by its counterpart, "The Rake's Progreſs." The very extraordinary merit of theſe productions, and the favourable reception they met with, ſoon induced the printſellers to be guilty of the baſe and mean conduct of having copies made of them, and thus rob the ingenious author of his well-earned reward.

To prevent this nefarious practice from continuing, Hogarth, in conjunction with Vertue and five other artiſts, in the year 1735, applied, by petition to the legiſlature, for a bill to protect their property, ſimilar to that for the ſecurity of copy-right in literary productions. A bill was conſequently paſſed to ſecure the property of an engraved plate to the original poſſeſſor of it for fourteen years from the firſt day of publication; which was to be ſpecified on the print. From this time, and owing more to this circumſtance than any other, prints have become a very conſiderable article of commerce in this country. Our artiſt commemorated the circumſtance, by an emblematical engraving, with an inſcription expreſſive of the ſubject; impreſſions from which he iſſued at various times, and on the publication of one of his electioneering prints in the following year, he made it the ſubſcription ticket.

Upon the ſecurity of this act, Hogarth employed himſelf with alacrity, and produced other works, which, while taſte and good ſenſe prevail in the world, will enſure the admiration of all who poſſeſs theſe uſeful qualities, by their ingenuity, and the force of their ſatire. In 1736 he publiſhed "The Sleeping Congregation;" "The Diſtreſſed Poet;" and ſome others of leſs note. In 1738 "The Four Parts of the Day; Morning, Noon, Evening, and Night;" "Strolling Actreſſes dreſſing in a Barn;" &c. In 1741, "The Enraged Muſician;" and in this and three following years, he appears to have laboured hard at a number of minor productions, and in preparing the plates of his moſt celebrated work, "The Marriage-à-la-mode," of which he had given notice in 1743. He had projected a counter-part to this ſubject of "A Happy Marriage," to be treated likewiſe in ſix prints; but one only of the deſigns for it was completed, and that was never engraved.

The very excellent and admired ſeries of prints juſt alluded to, were followed, in 1747, by thoſe of the "Induſtrious and Idle Apprentices;" works whoſe moral utility is felt and acknowledged by all. Gay's "Macheath in the Beggar's Opera," by his ſpirited gallantry, is ſaid to have been the cauſe of many a youth falling into bad courſes: it is hardly poſſible to calculate the efficacy of theſe prints in a contrary direction; probably much more than lectures or ſermons of the utmoſt eloquence could produce. The impreſſion they made at the time was almoſt incredible.

Hogarth's own account of the motives which induced him to publiſh theſe two ſeries do him infinite honour, and ſhew the nobleneſs of his views. "Theſe twelve prints were calculated for the inſtruction of young people, and every thing addreſſed to them is fully deſcribed in words as well as figures," &c.—"Conſidering the perſons they were intended to ſerve, I have endeavoured to render them intelligible, and as cheap as poſſible. Fine engraving is not neceſſary for ſuch ſubjects, if, what is infinitely more material, character and expreſſion is properly preſerved."—"Theſe prints I have always found ſell much more rapidly at Chriſtmas than at any other time."

Soon after the treaty of Aix la Chapelle, Hogarth, in ſearch after character and matter for the employment of his pencil, went over to France; but allowing his natural inclination to get the better of his judgment, and ſeduce him to draw "The Gate of Calais," of which he, after his return, publiſhed the humorous print under that title, he was prevented, by impriſonment in his lodgings, from proceeding beyond that town; and ſoon after compelled to go on board a ſhip and return to England.

In 1745, finding that, however great the ſucceſs of his prints might be, the public were not inclined to take his pictures off his hands, he was induced to offer ſome of them, and thoſe of the beſt he had then produced, for diſpoſal by way of auction; but after a plan of his own, *viz.* by keeping open a book to receive biddings from the firſt day of February to the laſt day of the ſame month, at 12 o'clock. The ticket of admiſſion to the ſale was his print of "The Battle of the Pictures;" a humorous production, in which he ingeniouſly upheld his aſſertions concerning the preference ſo unfairly given to old pictures, and the tricks of the dealers in them. See Nichol's and Ireland's Account of Hogarth.

The pictures thus diſpoſed of were,

Strolling Players dreſſing in a Barn	27	6	0

In 1746, having finiſhed his picture of "The March of the Guards towards Finchley," he offered propoſals for a print from it, and a ſcheme to diſpoſe of the picture itſelf, by a lottery of chances, at ſo low a price as three ſhillings, in addition to 7*s.* 6*d.* ſubſcribed for a print. Having diſpoſed of 1843 chances, he gave his remaining numbers, amounting to 167, to the Foundling hoſpital, one of which, when the plate was finiſhed, and the lottery drawn, in the year 1750, was fortunate, and that very extraordinary and ingenious production thus became the property of that Inſtitution; within whoſe walls it yet remains, with ſeveral other of his productions; particularly an excellent portrait of captain Thomas Coram, founder of the hoſpital, and an hiſtorical picture of "Moſes brought before Pharaoh's Daughter."—By this ſcheme, Hogarth obtained 300*l.* for the picture, obſerving, "that it was his only chance of being paid for his time: ſuch was the patronage of the arts at that period in England; now happily very highly increaſed, to the credit of the public, and the advancement of the practical part of the art at leaſt.

In the year in which the above-mentioned print was publiſhed, Hogarth was employed by the benchers of Lincoln's Inn to paint a picture for their hall, in conſequence of their having been bequeathed 200*l.* by lord Wyndham, chancellor of Ireland, for the purpoſe of ornamenting that room as they thought proper. On the propoſal of lord Mansfield, the voice of the members was given for a picture by our artiſt, and, unhappily for his reputation, he choſe a ſubject of an elevated and ſerious nature, "St. Paul before Felix." From one who preſumed to ſmile at the high eſtimation in which the real works of the renowned artiſts of Italy were held, and boaſted of his power to rival them, the world had a right to expect much.

Inſtead of anſwering ſuch expectation, he totally failed. In every requiſite for ſuch a work, it muſt be owned, by his beſt friends, this picture is wretchedly defective. It ſtill occupies its original ſituation, and exhibits an uſeful leſſon to thoſe who place too high a value on their natural talents; and teaches them not to waſte their powers on matters for which previous education has not prepared them; nor too readily to under-rate thoſe of others, exerted in a different manner. Every branch of the art of painting requires its appropriate ſtudies, and no man can combine materials with which he is unacquainted. Hogarth, employed to earn his bread from the firſt, had not the time or the means, in this country, to inform himſelf properly of what was grand and impreſſive in the art. That which was expreſſive in common life he felt, and delineated with great force, but with common-place effect. Selection of beauty, of dignity and grandeur, which this ſubject required, he evidently knew nothing of; and conſequently failed in his attempt to inſpire his figures with ſuch qualities.

Whether he felt this himſelf when the picture was completed may be doubted; but he certainly attempted to parry criticiſm, by ſatiriſing his own work, and publiſhed a ludicrous print of the ſubject, nearly of the ſame compoſition, but attempted to throw the effect upon Rembrandt's manner of etching. Upon advertiſing a print of the real picture, he adds, "On the firſt payment a receipt will be given, which receipt will contain a new print (*in the true Dutch taſte*) of "Paul before Felix;" which, after the ſubſcription is over, will not be ſold at a leſs price than one guinea each."

At the ſame time he advertiſed for ſale his moſt beautiful ſeries of pictures before mentioned, "The Marriage-a-la-mode," by a manner of bidding peculiar to himſelf; from which he excluded all dealers in pictures. The mode he adopted was by written tickets, on which ſubſcribers wrote their names and the price they would give. This was kept open for the ſpace of one month. But either the public were not alive to the beauties and excellencies of theſe incomparable works, or his manner of proceeding diſpleaſed them: for the fact is, there were few competitors, and they were ſold at the low price of 120 guineas, with their frames, to Mr. John Lane, of Hillingdon; on whoſe death they became the property of his nephew, colonel Cawthorne. Being offered at auction by Mr. Chriſtie, in 1792, the proprietor bought them in at 900 guineas. A ſhort time afterwards they were bought by Mr. Angerſtein, at the price of 1000 guineas, and with him they ſtill remain, juſtly and deſervedly admired for their fulneſs of character and expreſſion, and their beauty of compoſition, colouring, and execution, and are a complete falſification of Mr. Walpole's aſſertion, "that Hogarth was no painter."

In the following year, 1751, he publiſhed his moral and inſtructive prints of "Beer-ſtreet," "Gin-lane," and "The four Stages of Cruelty." The generous and truly humane motives which induced him to make the four laſt deſigns he himſelf has thus deſcribed: "Theſe prints were engraved with the hope of, in ſome meaſure, correcting that barbarous treatment of animals, the very ſight of which renders the ſtreets of our metropolis ſo diſtreſſing to every feeling mind. If they have had this effect, I am more proud of having been the author, than I ſhould be of having painted Raphael's cartoons."

During the time of which we have been treating concerning Hogarth's practice and ſtudies, he continued occaſionally to paint portraits; but it was not his forte. He produced, indeed, ſeveral acknowledged ſtrong likeneſſes, but without any elevation of ſentiment or character.

He now thought it proper, in order to juſtify and enforce many points upon which he had diſagreed and contended with other artiſts, to turn author. He had, in the year 1745, painted his own portrait with his dog; before him lay a pallette ſpread with colours, and on it was drawn a waving line, which he entitled "The Line of Beauty." In this, Hogarth had a deſign. It appeared an enigma, and he himſelf relates, that, "no Egyptian hieroglyphic ever amuſed for a time more than it did. Painters and ſculptors came to me to know the meaning of it, being as much puzzled with it as other people, till it came to have ſome explanation; then, and not till then, ſome found it out to be an old acquaintance of theirs."—"Others denied that there could be ſuch a rule either in art or nature, &c." See preface to the work, which, in 1753, he though fit to publiſh under the title of "*The Analyſis of Beauty*, written with a view of fixing the fluctuating ideas of *Taſte*." Its object is to ſhew that waving lines are the ſource of beauty; and that grace is ſuperadded, when that line is twiſted to a certain degree, and becomes ſerpentine. In it are numerous references to various objects repreſented in two prints, which he etched and publiſhed with the book, and in which, if he has not ſatisfactorily illuſtrated the whole of his intention, he has done enough to prove the truth of his main poſition. Every artiſt may obtain benefit by the peruſal of the work. It is divided into chapters, treating of thoſe points, which, in his mind, formed the baſis of beauty; *viz.* fitneſs, variety, ſymmetry, ſimplicity, intricacy, quantity; and he adds to theſe, others on lines, compoſitions with the waving line, compoſitions with the ſerpentine line, proportion, light and ſhade, colouring, the face, attitude, and action.

Hogarth, in the conſciouſneſs of the pencil, not the pen, being the inſtrument by which he could beſt illuſtrate his ingenious and original thoughts; at firſt intended to engage ſome literary perſon to write what he ſhould dictate, but ſoon diſcarded that idea: and having written his work, ſubjected it by parts to the correction of Dr. Morrell, after whoſe death, the Rev. Mr. Townley kindly undertook the unthankful taſk of caſtigation on a young author; who, nevertheleſs, profited ſo much by the remarks on the firſt pages, that he greatly advanced in facility of expreſſion as he proceeded with it. The ſtyle is plain and unadorned, but clear and intelligible.

His mode of illuſtration is original and ingenious. We are ſatisfied there is great truth in his principles and obſervations; and that the world of art is greatly indebted to him for the work, though there are many opinions in which we cannot coincide; and wiſh he had not indulged ſo freely in ill-natured and ſplenetic alluſions to perſons and things not connected with his ſubject. Theſe latter drew upon him, in conſequence, much invective and ſatire; and by his own account, "the uneaſineſs it occaſioned him, more than counterbalanced the pleaſure afforded by its general ſucceſs." See his own hiſtory, written by himſelf, in John Ireland's Illuſtrations, vol. iii. p. 103. where he has given much additional and ingenious reaſoning on the ſubject of his book, but ſpeaks ſorely of the unfairneſs of the attacks made upon him; which were many, and of no very delicate nature. In oppoſition to this, he had the favourable teſtimony of many learned men, (Warburton among them,) in its favour. It was tranſlated into German by Mylius, under the author's inſpection; and an Italian tranſlation was ſoon afterwards publiſhed at Leghorn.

In 1754, the members of the Imperial Academy at Augſburg, erected for the ſtudy and improvement of arts and letters, were induced, on the appearance of this work among them, to elect Hogarth a counſellor and honorary member. In addition to this high ſounding title, he had a more ſubſtantial benefit conferred upon him this year, by the appointment of ſerjeant painter to the king, which produced him 200*l*. per annum.

In 1755 he publiſhed the plates of the election, which was the laſt ſeries of prints he favoured the world with; but he afterwards ſent forth ſeveral ſingle prints, fraught with uſeful moral inſtruction, conveyed by ingenious ſatire on the public follies of the day. The moſt ſtriking among them, were, "The Cockpit," "Enthuſiaſm delineated," and "The Medley, or a ſatire on Credulity, Superſtition, and Fanaticiſm," which laſt appeared in 1762.

In the interim he made another unſucceſsful attempt at ſerious hiſtorical painting; and that under circumſtances particularly unfavourable to him; the failure in which, or rather the public circumſtances connected with it, was thought by many to have haſtened his end. He was induced by vanity to endeavour at rivalry with a picture, ſaid to be by Correggio, of "Sigiſmunda weeping over the Heart of her Lover." The conſequence was, what might juſtly have been expected, diſappointment, with the world at leaſt, however he might himſelf appreciate it. He ſet the ſame value upon it as its prototype had brought at ſale by public auction, *viz.* 400*l*. The nobleman for whom it was painted excuſed himſelf from taking it, and it remained with Hogarth to his death. It is at preſent in the poſſeſſion of Mr. Alderman Boydell. See an account of it in Ireland's and Nichol's Anecdotes, &c. of Hogarth.

It is lamentable, that a man ſo highly uſeful and honourable to his country and the arts he profeſſed, ſhould, by ſingularity, and by an impolitic, although upright mode of conduct, bring enemies upon himſelf as he advanced in years; who, unequal to cope with him for the bright rewards of genius, yet had influence enough in the world to ſting him, and that remorſeleſsly, by petty, paltry efforts. Theſe, though they could never ſeriouſly wound his fame, yet diſturbed his repoſe, and prevented the enjoyment of thoſe well earned encomiums the wiſe and virtuous were inclined to beſtow upon his meritorious efforts. Such, unhappily, was the fate of Hogarth. Strong in mind, original in reflection, and deeply reflective, but narrowed by want of education; he laviſhed abroad opinions peculiar to himſelf; oppoſing old and well-founded reaſonings, becauſe he ſaw more of their abuſe than of their utility. He appears to have been a humouriſt, but of the beſt claſs. He ſpoke his mind freely, heedleſs of the reſult. Its effect upon him proves to others who may be inclined to follow the ſame courſe, that it is not always to be purſued with impunity.

To ſhew that theſe remarks are well founded, we ſhall inſert his own account of his feelings on the obſervations made upon his Sigiſmunda; "the moſt violent and virulent abuſe thrown on Sigiſmunda was from a ſet of miſcreants, with whom I am proud of being *ever at war*. I mean *the expounders of the myſteries of old pictures*. I have been ſometimes told they were beneath my notice. This is true of them individually, but as they have acceſs to people of rank, who ſeem as happy in being cheated as theſe merchants are in cheating them, they have a power of doing much miſchief to modern artiſts. However mean the vender of poiſons, the mineral is deſtructive; *to me its operation was troubleſome enough*. Ill-nature ſpread ſo faſt, that now was the time for every little dog in the profeſſion to bark, and revive the old ſpleen which appeared at the time of the Analyſis. The anxiety that attends endeavouring to recollect ideas long dormant, and the misfortunes which clung to this tranſaction, coming at a time when nature demands quiet, and ſomething beſides exerciſe to cheer it, added to my long ſedentary life, *brought on an illneſs which continued twelve months*. But when I got well enough to ride on horſeback, I ſoon recovered."

In a ſtate thus irritable, goaded by malignity and envy, and reſting entirely upon his own conſcious rectitude, and the conſolation of a few friends, who knew how to eſtimate his talents and his genuine worth, for ſupport; he continued to employ himſelf on minor labours; till, in 1762, he unfortunately elicited a flame of enmity in the breaſts of two powerful antagoniſts, under whoſe united efforts he ſunk. Theſe were Wilkes and Churchill, whoſe great ingenuity and keen ſatire he drew upon himſelf, by exhibiting them in his print of "The Times," as incendiaries; fomenters of public diſturbances. His own account of this circumſtance we ſhall extract from J. Ireland's Illuſ. vol. iii. p. 212, et ſeq. "This being a period when war abroad, and contention at home filled every body's mind, prints were thrown into the back-ground, and the ſtagnation rendered it neceſſary that I ſhould do ſome *timed thing* to recover my loſt time, and ſtop a gap in my income. This drew forth my print of "The Times," a ſubject which tended to the reſtoration of peace and unanimity, and put the oppoſers of theſe humane objects in a light which gave great offence to thoſe who were trying to foment deſtruction in the minds of the populace. One of the moſt notorious among them, till now rather my friend and flatterer, attacked me in a North Briton, in ſo infamous and malign a ſtyle, that he himſelf, when puſhed, even by his beſt friends, was driven to ſo poor an excuſe, as to ſay, *he was drunk when he wrote it*. Being at that time very weak, and in a kind of ſlow fever, it could not but ſeize on a feeling mind. My philoſophical friends adviſe me to laugh at the nonſenſe of party-writing—who would mind it? But I cannot reſt myſelf." To revenge himſelf, he publiſhed a likeneſs of Wilkes, which doubtleſs he thought was the greateſt ſatire upon his pretenſion to political honeſty and heroic character that he could produce. This drew upon him Churchill the poet, who ſeverely treated him in an epiſtle, fraught with the groſſeſt abuſe and the utmoſt malignity, and even falſehood, though in ſome parts juſtly complimentary. All that the bitterneſs of reſentment could dictate, or the malevolence of the keeneſt ſatire inſpire, is poured forth in it upon the devoted Hogarth, who could only retort by a print of a bear with a pot of porter and a ragged ſtaff, on the knots of which was written lies, lies, lies!

This unhappy event Hogarth did not long ſurvive. It is ſaid that he did not ſuffer in mind by the coarſe attack of Churchill, ſo much as by the previous one by Wilkes; he ſays of it himſelf, that "it made no impreſſion, but perhaps in ſome meaſure effaced or weakened the black ſtrokes of the North Briton." And he concludes his own memoir by ſaying, "Thus have I gone through the principal circumſtances of a life which, till lately, paſſed pretty much to my own ſatisfaction, and I hope in no reſpect injurious to any other man. This I can ſafely aſſert, I have invariably endeavoured to make thoſe about me tolerably happy, and my greateſt enemy cannot ſay I ever did an intentional injury; though, without oſtentation, I could produce many inſtances of men that have been eſſentially benefited by me. What may follow God knows! Finis."

Such is the candid appeal, which, in conſciouſneſs of ſound principle and rectitude of heart, this excellent artiſt and well intentioned man made to his contemporaries and to poſterity. Let the human weakneſs he exhibited in common with his fellow men teach them, like his works, (which neceſſarily lead to moral reflection), that ſtrict government of the heart and mind, and kind indulgence to the infirmities of others, are the ſureſt guides to happineſs; here, as well as hereafter.

His laſt original production he termed Finis, the Bathos, or the Art of ſinking in Sublime Painting; which Mr. J. Ireland juſtly terms an enigmatical and pun-ical print. The origin and production of which he thus deſcribes.

After dinner, with a few ſocial friends at his own table, he was aſked what will be the ſubject of your next print? "The end of all things;" was his reply. If that ſhould be the caſe, added one of his friends, your buſineſs will be finiſhed, for there will be an end of the painter. With a look that conveyed a conſciouſneſs of approaching diſſolution, and a deep ſigh, he anſwered, "there will be ſo, and therefore, *the ſooner my work is done the better.*" With this impulſe, he next day began the plate, and ſeeming to conſider it as a *terminus to his fame*, never turned to the right or left until he arrived at the end of his journey.

The above print was publiſhed in March 1764, and in the October following, death put a *finis* to the labours of this extraordinary man, and deprived ſociety of one of its moſt uſeful members; who contributed alike to its amuſement and its improvement, and has left a perpetual fund of both for the benefit of future ages.

The following conciſely critical diſſertation upon the character and works of Hogarth, from the elegant pen of the late Horace Walpole, earl of Orford, we conceive will be agreeable to our readers, and prove a valuable addition to the above account of his life.

"Having diſpatched the herd of our painters in oil, I reſerved to a claſs by himſelf that great and original genius, Hogarth; conſidering him rather as a writer of comedy with a pencil, than as a painter. If catching the manners and follies of an age *living as they riſe*, if general ſatire on vices and ridicules, familiariſed by ſtrokes of nature, and heightened by wit, and the whole animated by proper and juſt expreſſions of the paſſions, be comedy, Hogarth compoſed comedies as much as Moliere; in his Marriage A-la-mode there is even an intrigue carried on throughout the piece. He is more true to character than Congreve; each perſonage is diſtinct from the reſt, acts in his ſphere, and cannot be confounded with any other of the dramatis perſonæ. The alderman's footboy, in the laſt print of the ſet I have mentioned, is an ignorant ruſtic; and if wit is ſtruck out from the characters in which it is not expected, it is from their acting conformably to their ſituation, and from the mode of their paſſions, not from their having the wit of fine gentlemen. Thus there is wit in the figure of the alderman, who, when his daughter is expiring in the agonies of poiſon, wears a face of ſolicitude, but it is to ſave her gold ring, which he is drawing gently from her finger. The thought is parallel to Moliere's, where the miſer puts out one of the candles as he is talking. Moliere, inimitable as he has proved, brought a rude theatre to perfection. Hogarth had no model to follow and improve upon. He created his art; and uſed colours inſtead of language. His place is between the Italians, whom we may conſider as epic poets and tragedians, and the Flemiſh painters, who are as writers of farce and editors of burleſque nature. They are the Tom Browns of the mob. Hogarth reſembles Butler, but his ſubjects are more univerſal; and amidſt all his pleaſantry, he obſerves the true end of comedy, reformation; there is always a moral to his pictures. Sometimes he roſe to tragedy, not in the cataſtrophe of kings and heroes, but in marking how vice conducts, inſenſibly and incidentally, to miſery and ſhame. He warns againſt encouraging cruelty and idleneſs in young minds, and diſcerns how the different vices of the great and the vulgar lead by various paths to the ſame unhappineſs. The fine lady in Marriage A-la-mode, and Tom Nero in the Four Stages of Cruelty, terminate their ſtory in blood,—ſhe occaſions the murder of her huſband; he aſſaſſinates his miſtreſs. How delicate and ſuperior too is his ſatire, when he intimates in the College of Phyſicians and Surgeons that preſide at a diſſection, how the legal habitude of viewing ſhocking ſcenes hardens the human mind, and renders it unfeeling. The preſident maintains the dignity of inſenſibility over an executed corpſe, and conſiders it but as the object of a lecture. In the print of the Sleeping Judges, this habitual indifference only excites our laughter.

"It is to Hogarth's honour that, in ſo many ſcenes of ſatire or ridicule, it is obvious that ill-nature did not guide his pencil. His end is always reformation, and his reproofs general. Except in the print of the Times, and the two portraits of Mr. Wilkes and Mr. Churchill, that followed, no man, amidſt ſuch a profuſion of characteriſtic faces, ever pretended to diſcover or charge him with the caricatura of a real perſon; except of ſuch notorious characters as Chartres and mother Needham, and a very few more, who are acting officially and ſuitably to their profeſſions. As he muſt have obſerved ſo carefully the operation of the paſſions on the countenance, it is even wonderful that he never, though without intention, delivered the very features of any identical perſon. It is at the ſame time a proof of his intimate intuition into nature; but had he been too ſevere, the humanity of endeavouring to root out cruelty to animals would atone for many ſatires. It is another proof that he drew all his ſtores from nature and the force of his own genius, and was indebted neither to models nor books for his ſtyle, thoughts or hints, that he never ſucceeded when he deſigned for the works of other men. I do not ſpeak of his early performances at the time that he was engaged by bookſellers, and roſe not above thoſe they generally employ; but in his maturer age, when he had invented his art, and gave a few deſigns for ſome great authors, as Cervantes, Gulliver, and even Hudibras, his compoſitions were tame, ſpiritleſs, void of humour, and never reach the merits of the books they were deſigned to illuſtrate. He could not bend his talents to think after any body elſe. He could think like a great genius rather than after one. I have a ſketch in oil that he gave me, which he intended to engrave; it was done at the time that the houſe of commons appointed a committee to enquire into the cruelties exerciſed on priſoners in the Fleet to extort money from them. The ſcene is the committee; on the table are the inſtruments of torture. A priſoner in rags, half ſtarved, appears before them; the poor man has a good countenance, that adds to the intereſt. On the other hand is the inhuman gaoler. It is the very figure that Salvator Roſa would have drawn for Iago in the moment of detection. Villany, fear, and conſcience, are mixed in yellow and livid on his countenance; his lips are contracted by tremor, his face advances as eager to lie, his legs ſtep back as thinking to make his eſcape; one hand is thruſt precipitately into his boſom, the fingers of the other are catching uncertainly at his button-holes. If this was a portrait, it is the moſt ſpeaking that ever was drawn; if it was not, it is ſtill finer.

“ It is ſeldom that his figures do not expreſs the character he intended to give them. When they wanted an illuſtration that colours could not beſtow, collateral circumſtances, full of wit, ſupply notes. The nobleman in Marriage A-la-mode has a great air—the coronet on his crutches, and his pedigree iſſuing out of the bowels of William the Conqueror, add to his character. In the Breakfaſt the old ſteward reflects for the ſpectator. Sometimes a ſhort label is an epigram, and is never introduced without improving the ſubject. Unfortunately ſome circumſtances, that were temporary, will be loſt to poſterity, the fate of all comic authors; and if ever an author wanted a commentary, that none of his beauties might be loſt, it is Hogarth—not from being obſcure (for he never was that but in two or three of his firſt prints, where tranſient national follies, as lotteries, free-maſonry, and the South-ſea, were his topics), but for the uſe of foreigners, and from a multiplicity of little incidents, not eſſential to, but always heightening, the principal action. Such is the ſpider's-web extended over the poor's box in a pariſh-church; the blunders in architecture in the nobleman's ſeat ſeen through the window, in the firſt print of Marriage A-la-mode; and a thouſand in the Strollers dreſſing in a Barn, which for wit and imagination, without any other end, I think the beſt of all his works; as for uſeful and deep ſatire, that on the Methodiſts is the moſt ſublime. The ſcenes of Bedlam and the Gaming-houſe are inimitable repreſentations of our ſerious follies or unavoidable woes; and the concern ſhewn by the lord-mayor, when the companion of his childhood is brought before him as a criminal, is a touching picture, and big with humane admonition and reflection.

“ Another inſtance of this author's genius, is his not condeſcending to explain his moral leſſons by the trite poverty of allegory. If he had an emblematic thought, he expreſſed it with wit, rather than by a ſymbol. Such is that of the whore ſetting fire to the world in the Rake's Progreſs. Once indeed he deſcended to uſe an allegoric perſonage, and was not happy in it; in one of his election prints Britannia's chariot breaks down while the coachman and footman are playing at cards on the box. Sometimes too, to pleaſe his vulgar cuſtomers, he ſtooped to low images and national ſatire, as in the two prints of France and England, and that of the Gates of Calais. The laſt indeed has great merit, though the caricatura is carried to exceſs. In all theſe the painter's purpoſe was to make his countrymen obſerve the eaſe and affluence of a free government, oppoſed to the wants and woes of ſlaves. In Beer-ſtreet the Engliſh butcher toſſing a Frenchman in the air with one hand, is abſolute hyperbole; and what is worſe, was an after-thought, not being in the firſt edition. The Gin-alley is much ſuperior, horridly fine, but diſguſting.

“ His Bartholomew-fair is full of humour; the March to Finchley, of nature; the Enraged Muſician tends to farce. The Four Parts of the Day, except the laſt, are inferior to few of his works. The Sleeping Congregation, the Lecture on the Vacuum, the Laughing Audience, the Conſultation of Phyſicians as a coat of arms, and the Cockpit, are perfect in their ſeveral kinds. The prints of Induſtry and Idleneſs have more merit in the intention than execution.

“ Towards his latter end he now and then repeated himſelf, but ſeldomer than moſt great authors who executed ſo much.

“ It may appear ſingular, that of an author whom I call comic, and who is ſo celebrated for his humour, I ſhould ſpeak in general in ſo ſerious a ſtyle; but it would be ſuppreſſing the merits of his heart to conſider him only as a promoter of laughter. I think I have ſhewn that his views were more generous and extenſive. Mirth coloured his pictures, but benevolence deſigned them. He ſmiled like Socrates, that men might not be offended at his lectures, and might learn to laugh at their own follies. When his topics were harmleſs, all his touches were marked with pleaſantry and fun. He never laughed, like Rabelais, at nonſenſe that he impoſed for wit; but, like Swift, combined incidents that divert one from their unexpected encounter, and illuſtrate the tale he means to tell. Such are the hens rooſting on the upright waves in the ſcene of the Strollers, and the devils drinking porter on the altar. The manners or *coſtume* are more than obſerved in every one of his works. The very furniture of his rooms deſcribe the characters of the perſons to whom they belong; a leſſon that might be of uſe to comic authors. It was reſerved to Hogarth to write a ſcene of furniture. The rake's levee-room, the nobleman's dining-room, the apartments of the huſband and wife in Marriage A-la-mode, the alderman's parlour, the poet's bedchamber, and many others, are the hiſtory of the manners of the age.

“ But perhaps too much has been ſaid of this great genius as an author; it is time to ſpeak of him as a painter, and to mention the circumſtances of his life, in both which I ſhall be more brief. His works are his hiſtory.

“ His apprenticeſhip was no ſooner expired, than he ſtudied drawing from the life, in which he never attained to great excellence. It was character, the paſſions, the ſoul, that his genius was given him to copy: his force lay in expreſſion, not in tints and chiaro-ſcuro. At firſt he worked for bookſellers, and deſigned and engraved plates for ſeveral books; and, which is extraordinary, no ſymptom of genius dawned in thoſe plates. His Hudibras was the firſt of his works that marked him as a man above the common; yet what made him then noticed, now ſurpriſes us to find ſo little humour in an undertaking ſo congenial to his talents. On the ſucceſs however of thoſe plates he commenced painter, a painter of portraits; the moſt ill-ſuited employment imaginable to a man whoſe turn certainly was not flattery, nor his talent adapted to look on vanity without a ſneer. Yet his facility in catching a likeneſs, and the method he choſe of painting families and converſations in ſmall, then a novelty, drew him prodigious buſineſs for ſome time. It did not laſt, either from his applying to the real bent of his diſpoſition, or from his cuſtomers apprehending that a ſatiriſt was too formidable a confeſſor for the devotees of ſelf-love.

“ His Midnight Modern Converſation was the firſt work that ſhewed his command of character: but it was the Harlot's Progreſs, publiſhed in 1729 or 1730, that eſtabliſhed his fame. The pictures were ſcarce finiſhed, and no ſooner exhibited to the public, and the ſubſcription opened, than above twelve hundred names were entered on his book. The familiarity of the ſubject, and the propriety of the execution, made it taſted by all ranks of people. Every engraver ſet himſelf to copy it, and thouſands of imitations were diſperſed all over the kingdom. It was made into a pantomime, and performed on the ſtage. The Rake's Progreſs, perhaps ſuperior, had not ſo much ſucceſs, from want of novelty; nor indeed is the print of the Arreſt equal in merit to the others.

" The curtain was now drawn aſide, and his genius ſtood diſplayed in its full luſtre. From time to time he continued to give thoſe works that ſhould be immortal, if the nature of his art will allow it. Even the receipts for his ſubſcriptions had wit in them. Many of his plates he engraved himſelf, and often expunged faces etched by his aſſiſtants when they had not done juſtice to his ideas.

" Not content with ſhining in a path untrodden before, he was ambitious of diſtinguiſhing himſelf as a painter of hiſtory. But the genius that had entered ſo feelingly into the calamities and crimes of familiar life, deſerted him in a walk that called for dignity and grace. The burleſque turn of his mind mixed itſelf with the moſt ſerious ſubjects. In his Danaë the old nurſe tries a coin of the golden ſhower with her teeth, to ſee if it is true gold: in the Pool of Betheſda, a ſervant of a rich ulcerated lady beats back a poor man that ſought the ſame celeſtial remedy. Both circumſtances are juſtly thought, but rather too ludicrous. It is a much more capital fault that Danaë herſelf is a mere nymph of Drury. He ſeems to have conceived no higher idea of beauty.

" So little had he eyes to his own deficiencies, that he believed he had diſcovered the principle of grace. With the enthuſiaſm of a diſcoverer, he cried, Eureka! This was his famous line of beauty, the ground-work of his Analyſis, a book that has many ſenſible hints and obſervations, but that did not carry the conviction, nor meet the univerſal acquieſcence he expected.

" He fell afterwards into a groſſer miſtake. From a contempt of the ignorant virtuoſi of the age, and from indignation at the impudent tricks of picture-dealers, whom he ſaw continually recommending and vending vile copies to bubble-collectors, and from having never ſtudied, indeed having ſeen, few good pictures of the great Italian maſters, he perſuaded himſelf that the praiſes beſtowed on thoſe glorious works were nothing but the effects of prejudice. He talked this language till he believed it; and having heard it often aſſerted, as is true that time gives a mellowneſs to colours and improves them, he not only denied the propoſition, but maintained that pictures only grew black and worſe by age, not diſtinguiſhing between the degrees in which the propoſition might be true or falſe. He went farther; he determined to rival the ancients—and, unfortunately, choſe one of the fineſt pictures in England as the object of his competition. This was the celebrated Sigiſmonda of ſir Luke Schaub, now in the poſſeſſion of the duke of Newcaſtle, ſaid to be painted by Correggio, probably by Furnio, but no matter by whom. It is impoſſible to ſee the picture, or read Dryden's inimitable tale, and not feel that the ſame ſoul animated both. After many eſſays, Hogarth at laſt produced *his* Sigiſmonda—but no more like Sigiſmonda, than I to Hercules. None of the ſober grief, no dignity of ſuppreſſed anguiſh, no involuntary tear, no ſettled meditation on the fate ſhe meant to meet, no amorous warmth turned holy by deſpair; in ſhort, all was wanting that ſhould have been there. He ſet the price of 400*l.* on it, and had it returned on his hands by the perſon for whom it was painted. He took ſubſcriptions for a plate of it, but had the ſenſe at laſt to ſuppreſs it. I make no more apology for this account than for the encomiums I have beſtowed on him. Both are dictated by truth, and are the hiſtory of a great man's excellencies and errors. Milton, it is ſaid preferred his Paradiſe Regained to his immortal poem.

" The laſt memorable event of our artiſt's life was his quarrel with Mr. Wilkes, in which, if Mr. Hogarth did not commence direct hoſtilities on the latter, he at leaſt obliquely gave the firſt offence, by an attack on the friends and party of that gentleman. This conduct was the more ſurpriſing, as he had all his life avoided dipping his pencil in political conteſts, and had early refuſed a very lucrative offer that was made to engage him in a ſet of prints againſt the head of a court-party. Without entering into the merits of the cauſe, I ſhall only ſtate the fact. In September 1762 Mr. Hogarth publiſhed his print of the Times. It was anſwered by Mr. Wilkes in a ſevere North-Briton. On this the painter exhibited the caricatura of the writer. Mr. Churchill, the poet, then engaged in the war, and wrote his epiſtle to Hogarth, not the brighteſt of his works, and in which the ſevereſt ſtrokes fell on a defect that the painter had neither cauſed nor could amend—his age; and which, however, was neither remarkable nor decrepit; much leſs had it impaired his talents, as appeared by his having compoſed but ſix months before one of his moſt capital works, the ſatire on the Methodiſts. In revenge for this epiſtle, Hogarth caricatured Churchill under the form of a canonical bear, with a club and a pot of porter—*et vitulâ, tu dignus et hic*—never did two angry men of their abilities throw mud with leſs dexterity.

" He ſold about twenty-four of his principal pictures by auction in 1745. Mr. Vincent Bourne addreſſed a copy of Latin hendecaſyllables to him on his chief pictures; and Roquet, the enameller, publiſhed a French explanation, though a ſuperficial one, of many of his prints, which it was ſaid, he had drawn up for the uſe of marſhal Belleiſle, then a priſoner in England."

HOGBO, in *Geography*, a town of Sweden, in the province of Geſtricia; 9 miles W. of Geffle.

HOGDAL Osver, a town of Sweden, in Harjedalen; 76 miles N.W. of Hudwickſwall.

Hogdal, *Utter*, a town of Sweden, in Helſingland; 70 miles N.W. Hudwickſwall.

HOGENPOUR, in *Geography*, a town of Hindooſtan, in Bednore.

HOGERUS, in *Biography*, an abbot, who is ſaid to be the author of a curious MS. treatiſe on muſic, N° CCLX, in the library of Bene't college, Cambridge; where it is entitled "Muſica Hogeri, ſive Excerptiones Hogeri Abbatis ex Autoribus Muſicæ Artis:" "The Muſic of Hogerus, or Extracts from Writers on the Art of Muſic, by the Abbot Hogerus." Who this abbot was, or when he lived, will not now be eaſily diſcovered. His name has long puzzled the learned: and we find, among the letters of Baptiſta Doni, that this MS. was a ſubject of a correſpondence between him and Dr. Thomas Rigel, of London, in the year 1639. Doni, who had emiſſaries at this time all over Europe, in ſearch of muſical curioſities, upon hearing of this extraordary MS. in his letter to Dr. Rigel concerning it, ſays "De Hogerii abbatis excerptis (ſiquidem exſtarent) brevia quædam ſpecimina dumtaxat cuperem: quum enim autor ſit mihi plane ignotus, affirmare non auſim, an talia ſint ejus ſcripta, ut totus ſcribi mereatur."—The doctor, in his reply to Doni, the ſame year, tells him, that after making all poſſible inquiry in the library at Cambridge—"Nullum Hogerii ſcriptum in ea bibliotheca inveniri." Whether this was true, or only a ſhort way of getting rid of the trouble incident to ſuch inquiries, we know not; but we find the book entered in the catalogue that goes under the name of Dr. Gale, thus: "Excerptiones Rogeri Baconi ex auctoribus Muſicæ Artis." It is poſſible that this book may have been tranſcribed by, or for, this powerful man; and it is the more poſſible, as he admitted muſic among his ſtudies, and is ſaid, by his biographers, to have written "De valore Muſices, pr. Secundum Boetium et cæteros auctores." However this may have been, the MS. which is beautifully written on vellum, and extremely well preſerved, contains more than it promiſes; for the two muſical treatiſes of Hubald and Odo, both written in the tenth century, are not given in fragments or abſtracts, but entire, and unmixed with the writings of any other authors. See HUBALD and ODO.

HOGGENBERG, in *Geography*, a town of Auſtria; 12 miles S.W. Freyſtadt.

HOGGEREL, a name that ſignifies the ſame thing with *hog-ſheep*, in particular diſtricts.

HOGGET, or HOGREL, is a young boar of the ſecond year.

HOGGIT denotes the male or wedder ſheep, from the period of taking it from the ewe, to the time of its attaining the age of one year.

HOGI, in the *Eaſtern Churches*, as at Cairo, is an under attendant on the moſque, who is the reader under the ſheick.

HOGKNE, in *Geography*, a town of Aſiatic Turkey, in the government of Moſul; 32 miles W. of Moſul.

HOGLAND, a town of Norway, in the dioceſe of Aggerhuus; 32 miles N. of Frederickſtall.

HOGOE, properly *Haut-Gout*, a meſs in cookery, ſo denominated from its high ſavour, or reliſh.

HOGOLIN, or HOGOLEU, in *Geography*, one of the Caroline iſlands, or New Philippines; about 90 Britiſh miles in length, by 40 in breadth.

HOGSBY, a town of Sweden, in the province of Smaland; 33 miles N. of Calmar.

HOGSHEAD, a meaſure of capacity, and is of ſeveral kinds, *viz.*

HOGSHEAD *of Ale or Beer*, in the country, is 51 ale gallons = 204 ale quarts = 408 ale pints = $1\frac{1}{2}$ barrel = 3 country kilderkins = 6 country firkins = $\frac{17}{18}$ths, or .9444 London beer hogſheads = $\frac{17}{16}$ths, or 1.0625 London ale hogſheads = .9825 wine hogſheads = 14382 cubic inches = 8.32291 cubic feet = .30568 cubic yards = 28.9616 cubic links.

HOGSHEAD *of Ale*, in London, is 48 ale gallons = 192 ale quarts = 384 ale pints = $1\frac{1}{2}$ London ale barrel = 3 London ale kilderkins = 6 London ale firkins = $\frac{16}{17}$ths, or .941176 country ale or beer hogſheads = $\frac{8}{9}$ths, or .8888 London beer hogſheads = .930117 wine hogſheads = 13536 cubic inches = $7\frac{5}{6}$ths, or 7.8333 cubic feet = .290123 cubic yards = 27.25804 cubic links.

HOGSHEAD *of Beer*, in London, is 54 ale gallons = 216 ale quarts = 432 ale pints = $1\frac{1}{2}$ London beer barrel = 3 London beer kilderkins = 6 London beer firkins = $\frac{9}{8}$ths, or 1.125 London ale hogſheads = $\frac{18}{17}$ths, or 1.058824 country ale or beer hogſheads = 1.04638 wine hogſheads = 15228 cubic inches = 8.8125 cubic feet = .32638 cubic yards = 30.66526 cubic links.

HOGSHEAD *of Wine, Cyder, Mead, Metheglin, Olives*, &c. (5 Ann.) is 63 wine gallons = 252 wine quarts = 504 wine pints = 2016 wine gills = $1\frac{1}{2}$ tierce = 2 wine barrels = $3\frac{1}{2}$ rundlets = 1.011649 country ale or beer hogſheads = 1.07513 London ale hogſheads = .955673 London beer hogſheads = 14553 cubic inches = 8.4219 cubic feet = .311921 cubic yards = 29.30601 cubic links.

HOGSHEAD *of Water*, in *Engineery*, according to Beighton, Harris (Lexicon Tech. Meaſures and Smeaton's Rep. vol. i. p. 214.) is 63 ale gallons = 17766 cubic inches = 10.28125 cubic feet = $\frac{7}{6}$ths London beer hogſheads = 35.76137 cubic links: but, according to Mr. Smeaton, (Reports, vol. i. p. 245, 247, &c.) it is 52 ale gallons = 14664 cubic inches = 8.4861 cubic feet = 29.51732 cubic links. Dr. Deſaguliers uſed the London beer hogſhead of 54 gallons in his experiments on pumping.

HOGSHEAD *of Lime* in Somerſetſhire, is five heaped buſhels or bags, (ſee Bath Soc. Papers, vol. x. p. 58.) = .078125 carriages.

HOGSIO, in *Geography*, a town of Sweden, in the province of Angermanland; 14 miles N.N.W. of Hernoſand.

HOGSTA, a town of Sweden, in the province of Upland; 7 miles N. of Upſal.

HOGSTIES, one of the ſmall Bahama iſlands, ſurrounded with rocks. N. lat. 21° 40′. W. long. 73° 50′.

HOGSUND, a town of Norway, in the province of Aggerhuus; 23 miles S.W. of Chriſtiania.

HOGUE, LA, a town of France, in the department of the Channel; oppoſite to which was fought, in 1692, the battle of la Hogue, in which the Engliſh fleet, under admiral Ruſſel, obtained a glorious victory over the French, and 15 French men of war were taken, burned, or deſtroyed; 5 miles S. of Barfleur. N. lat. 49° 35′. W. long. 1° 11′.

HOGUE, *Belle*, a cape on the N. coaſt of the iſland of Jerſey; 5 miles N. of St. Helier.

HOGWALTA, a town of Sweden, in Warmeland; 30 miles N.W. of Carlſtadt.

HOHENBERG, a county and principality of Germany, ſituated between Wurtemberg and the Auſtrian Briſgaw. It is divided into Upper and Lower counties, lying at ſome diſtance from each other. The chief towns are Rotenburg, Ehingen, Hord, and Schramberg.—Alſo, a town of Germany, in the principality of Bayreuth; 10 miles E.N.E. of Wunſiedel.—Alſo, a town of the biſhopric of Bamberg; 5 miles E.N.E. of Kupferberg.

HOHENBURG, a town of Auſtria, on the river Traſen; 20 miles W. of Ebenfurth.

HOHENECK, a town and caſtle of Germany, in the principality of Bayreuth; 14 miles N. of Anſpach.

HOHEN-ELB, a town of Bohemia, in the circle of Konigingratz; 23 miles N. of Konigingratz. N. lat. 50° 30′. E. long. 15° 30′.

HOHENEMBS, a county and principality ſituated to the S. of the lake of Conſtance.

HOHENESTED, a town of the duchy of Holſtein; 10 miles S.W. of Nordtorp.

HOHENFELS, a town of Bavaria, in the lordſhip of Brieteneck; 17 miles N.N.W. of Ratiſbon.

HOHEN-FREDEBERG, a town of Sileſia, in the province of Schweidnitz; 5 miles N.N.W. of Freyburg.

HOHENFURT, a town of Bohemia, on the Molda; 4 miles S.S.W. of Roſenberg.

HOHEN-LIMBURG, a town of Germany, in the county of Mark; 9 miles S. of Schwiert.

HOHENLOE, or HOLACH, a county and principality of Germany, W. of the marggravate of Anſpach, about 26 miles from N. to S. and 23 from E. to W.; conſiſting of mountains, vallies, and plains. The ſouthern parts abound with vineyards, and the northern are cultivated for corn: the vallies have excellent meadows and paſture land, which feed great numbers of a valuable kind of cattle: and the mountains are clothed with oak, fir, pine, beech, and birch, and ſupply plenty of game. The inhabitants are chiefly Lutherans, intermixed with ſome Roman Catholics.

HOHENMAUT, or Wissoky-meyto, a town of Bohemia, in the circle of Chrudim, with a ſmall territory annexed; 14 miles E. of Chrudim. N. lat. 49° 54′. E. long. 15° 56′.

HOHENSCHAU, a town and caſtle of Bavaria, near which are iron mines and forges; 70 miles W. of Salzburg.

HOHEN-SOLMS, a town of Germany, whence a branch of the family of Solms derives the title of count, ſituated in a valley near a high mountain, and inhabited by Calviniſts, though the ſurrounding villages are occupied by Lutherans; 5 miles N.N.E. of Wetzlar. N. lat. 50° 38′. E. long. 8° 35′.

HOHENSTADT, or Zabrech, a town of Moravia, in the circle of Olmutz; 24 miles N.W. of Olmutz. N. lat. 49° 49′. E. long. 61° 41′.

HOHENSTEIN, a town of Pruſſia, in the province of Oberland, with a caſtle. N. lat. 53° 27′. E. long. 20° 15′.—Alſo, a town of Saxony, in the marggravate of Meiſſen; 9 miles E.N.E. of Pirna. N. lat. 50° 56′. E. long. 14° 10′.

HOHENWART, a town of Bavaria; 9 miles S. of Ingolſtadt.

HOHENZOLLERN, a principality of Germany, divided into three branches, *viz.* Hohenzollern, Heckingen, and Hohenzollern Sigmaringen: each prince having a revenue of about 30,000 florins.

HOHNSTEIN, a county of Weſtphalia, ſituated in Thuringia.

HOIET, a ſmall iſland in the Eaſt Indian ſea, near the coaſt of Queda. N. lat. 6° 36′. E. long. 99° 47′.

HOJILAMSA, a town on the E. coaſt of the iſland of Celebes. N. lat. 0° 51′. E. long. 124° 59′.

HOIN, a town of Perſia, in the province of Adirbeitzan; 42 miles S.S.E. of Ardebil.

HOIST, in *Sea Language*, denotes the perpendicular height of a flag or enſign, as oppoſed to the *fly*, which ſignifies its breadth from the ſtaff to the outer edge.

HOISTING ſignifies the operation of drawing up any body by the aſſiſtance of one or more tackles. Hoiſting is never applied to the act of pulling up any body by the help of a ſingle block, except in the exerciſe of extending the ſails, by drawing them upwards along the maſt or ſtays, to which it is invariably applied.

Hoisting *Jack*, in *Mechanics*, is a machine uſed for raiſing large weights to ſmall heights, under which they can be placed. They are of two kinds; one in which a rack is puſhed upwards by means of a pinion and winch-handle, and wheels, when great power is required; and others, in which a ſcrew is moved upwards by means of a revolving nut, turned by a lever. In the Repoſitory of the Society of Arts in the Adelphi, two models of hoiſting-jacks are preſerved for public inſpection, *viz.* Mr. Abraham Staghold's, claſs iv. N° 47, deſcribed in Tranſ. Soc. Arts, vol. i. p. 319, and Bailey's Machines, vol. i. 168; and Mr. William Mocock's claſs iv. N° 116. vol. vii. 239. and vol. viii. p. 179. See Jack.

Hoisting *Tackle*, is an ingenious and very effective way of raiſing weights, lately introduced very extenſively by Mr. Simeon Thompſon, who has a patent for its application.

HOITLALLOTL, in *Ornithology*, the courier pheaſant of Latham. See Phasianus *Mexicanus*.

HOITLING, in *Ichthyology*. See Gadus *Merlangus*.

HOITZANATL, in *Ornithology*. See Corvus *Mexicanus*.

HOITZITLIN. See Certhia *Cærulea*, and Certhia *Mexicana*.

HOITZTLACUATZIN, in *Zoology*. See Hystrix *Prehenſilis*.

HOIZITZILTOTOTL, in *Ornithology*. See Trochilus *Punctulatus*.

HOKE-DAY, Hock-day, or *Hock-Tueſday*, in our *Ancient Cuſtoms*, (*Dies Martis, quam quindenam Paſchæ vocant*), the ſecond Tueſday after Eaſter week: a ſolemn feſtival celebrated for many ages in England, in memory of the great ſlaughter of the Danes in the time of king Ethelred II. in 1002; they having been, in that reign, almoſt all deſtroyed in one day in the different parts of the kingdom, and that principally by women. Mr. Bryant apprehends, that a holiday could not have been inſtituted for the commemoration of ſo cruel an event, which afforded matter for humiliation and ſorrow rather than of feſtivity and mirth. Others have, therefore, thought that Hoke-day alluded to the death of Hardicanute, the laſt monarch of the Daniſh race, at a marriage-feaſt in Lambeth, on the 8th of June, 1042; by whoſe death, the Engliſh were for ever releaſed from the wanton inſults and boundleſs exactions of him and his countrymen. (See a Memoir on Hoke-day, by the Rev. Mr. Denne, in the Archæologia, vol. vii. p. 244.) This is ſtill kept up in ſome counties, and the women bear the principal ſway in it, ſtopping all paſſengers with ropes and chains, and exacting ſome ſmall matter from them to make merry with. This day was very remarkable in former times, inſomuch as to be uſed on the ſame footing with Michaelmas, for a general term or time of account. We find leaſes without date, reſerving ſo much rent payable *ad duos anni terminos, ſcil. ad le hoke-day, et ad feſtum ſancti Michaelis*. In the accounts of Magdalen college, Oxford, there is yearly an allowance, *pro mulieribus hockantibus*, of ſome manors of theirs in Hampſhire; where the men *hock* the women on Mondays, and the women *hock* them on Tueſdays. The meaning of it is, that, on that day, the women in merriment ſtopped the way with ropes, and pulled paſſengers to them, deſiring ſomething to be laid out for pious uſes.

Hoke-day *Money*, or *Hoke-Tueſday Money*, a tribute anciently paid the landlord for giving his tenants and bondmen leave to celebrate hock-day, or hoke-day, in memory of the expulſion of the domineering Danes.

HOKE-NORTON, in *Geography*, a village of England, in the county of Oxford, where the Danes were defeated by the Saxons, under Edward the Elder, about the year 914. Veſtiges of the camps are yet viſible; 5 miles N.N.E. of Chipping Norton.

HO-KIEN, a city of China, of the firſt rank, in the province of Pe-tcheli, ſituated between two rivers abounding in fiſh, and remarkable for the neatneſs of its ſtreets. It has under its juriſdiction two cities of the ſecond, and fifteen of the third claſs; 87 miles S. of Peking. N. lat. 38° 28′. E. long. 115° 43′.

HOLAIVA, or Hoolaiva, one of the Hapaee iſlands, in the South Pacific ocean, uncultivated and uninhabited when Capt. Cook viſited it in 1777, except by one man employed in catching fiſh and turtle. The trees and plants are ſimilar to thoſe of Lefooga, to which it is joined by a reef that is dry at low water; 30 miles N.N.E. of Annamooka. N. lat. 19° 52′. E. long. 185° 36′.

HOLAMIN, a ſmall iſland of Scotland, near the S.W. coaſt of Mull. N. lat. 59° 19′. W. long. 61° 21′.

HOLANDS, a town of Norway, in the dioceſe of Chriſtianſand; 8 miles S. of Stavanger.

HOLARRHENA, in *Botany*, from ὅλος, *entire*, or *ſolid*, and ἀῤῥην, *a male*; apparently alluding to the anthers being entirely filled with pollen, and unaccompanied by ſuperfluous appendages. Brown Apocin. (from Tr. of the Wernerian Soc. v. 1.) p. 51.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ. Brown.

Eſſ. Ch. Corolla ſalver-ſhaped, with equi-lateral ſegments; its orifice and tube deſtitute of ſcales. Stamens incloſed in the tube, and inſerted into its baſe; anthers unconnected with the ſtigma, lanceolate, entire, burſting lengthwiſe. Germens two; ſtyle very ſhort; ſtigma common, cylindrical. No ſcales at the baſe of the germens. Follicles ſlender.

This genus conſiſts of two ſpecies, natives of Ceylon or other parts of the Eaſt Indies. One of them is *Cariſſa mitis*, Vahl. Symb. faſc. 3. 44, ſo named originally by Koenig, from whom there is a ſpecimen in the Bankſian herbarium. They are upright ſmooth ſhrubs, with membranous *leaves*. The *flowers* grow in terminal and lateral cymes.

HOLBEACH, in *Geography*, is an ancient market-town, and pariſh in the wapentake of Elloe, Holland diviſion of Lincolnſhire, England. It is ſituated in the Fens; and very indifferently built. A grant of a weekly market and an annual fair was obtained from Henry III. by Thomas de Malton, lord Egremont, about the middle of the thirteenth century; when a ſtone croſs was erected in the market-place. The chief building in Holbeach is the church, which is a large handſome ſtructure; and conſiſts of a nave, chancel, aiſles, porch, and ſquare tower, with an octangular ornamental ſpire. The north porch has two circular towers, with embattled parapets, at its extreme angles. The church contains ſome fine monuments. An hoſpital was eſtabliſhed and endowed in this town by ſir John de Kirton, knt. about the year 1350, for the ſupport of a warden, chaplain, and fourteen penſioners. A free grammar-ſchool was alſo founded here about the ſame time by a licence from king Edward III., who granted certain lands for its ſupport. Another free-ſchool was eſtabliſhed here about the year 1670, by George Farmer, eſq. and the revenues for its ſupport have been much increaſed by ſubſequent donations and bequeſts. Holbeach is 106 miles diſtant from London, and contains 556 houſes, occupied by 2683 perſons. This town has derived ſome honour from two eminent natives; Henry de Rands, called, from the place of his birth, Holbech, who was biſhop of Lincoln in the reign of Edward VI.; and Dr. William Stukeley, whoſe name and memory are reſpected by every admirer of Engliſh antiquities.

The village of Gedney, a mile and half diſtant from Holbeach, is worthy notice for the lightneſs of its church, which has fifty-three windows; in thoſe of the north aiſle are conſiderable remains of fine painted glaſs. Beauties of England, vol. ix.

HOLBECK, a ſea-port town of Denmark, in the iſland of Zealand, ſituated in the gulf of Heſiord, with a good harbour, whence conſiderable quantities of corn are annually exported; 30 miles W. from Copenhagen. N. lat. 55° 42′. E. long. 11° 44′.

HOLBEIN, John, or Hans, in *Biography*. This admirable painter was born at Baſle in 1498, and inſtructed in the art by his father John Holbein. In the early part of his life he purſued his ſtudies with inceſſant aſſiduity; and being poſſeſſed of an elevated genius, his progreſs was exceedingly rapid, ſo that he ſoon became far ſuperior to his inſtructor. He excelled all his contemporaries in portrait; and in that ſtyle arrived at ſo high a degree of perfection, that Zucchero, who certainly was well qualified to judge of his merit, did not heſitate to compare his portraits with thoſe of Raphael and Titian.

He painted equally well in oil, water-colours, and diſtemper, in large and in miniature; but he had never practiſed the art of painting in miniature, till he reſided in England, and learned it from Lucas Cornelii; though he afterwards carried it to its higheſt perfection. His paintings of that kind have all the force of oil-colours, and are finiſhed with the utmoſt delicacy. In general he painted on a green ground, but in his ſmall pictures frequently he painted on a blue.

The invention of Holbein was ſurpriſingly fruitful, and often poetical; his execution was remarkably quick, and his application indefatigable. His pencil was exceedingly delicate; his colouring had a wonderful degree of force; he finiſhed his pictures with exquiſite neatneſs; and his carnations were life itſelf. His genuine works are always diſtinguiſhable by the true, round, lively imitation of fleſh, viſible in all his portraits, and alſo by the amazing delicacy of his finiſhing.

He viſited London at the requeſt of Eraſmus, who recommended him to ſir Thomas More; and ſir Thomas immediately employed him, ſhewed him every mark of reſpect and real friendſhip, entertained him at his own table, allowed him an apartment in his houſe, and detained him for three years. In which time he painted the portraits of his patron, and all the family of ſir Thomas; as alſo ſeveral portraits of his relations and friends, which were hung up in a grand hall. As ſoon as king Henry VIII. beheld thoſe performances, he was ſo ſtruck with their beauty, their life, and admirable likeneſs, that he took Holbein into his ſervice, and favoured him highly as long as he lived.

It is obſerved by moſt authors, that Holbein always painted with his left hand; though one modern writer objects againſt that tradition, (what he conſiders as a proof,) that in a portrait of Holbein painted by himſelf, which was in the Arundelian collection, he is repreſented holding the pencil in the right hand. But, with great deference to the opinion of that ingenious connoiſſeur, that evidence cannot be ſufficient to ſet aſide ſo general a teſtimony of the moſt authentic writers on this ſubject; becauſe, although habit and practice might enable him to handle the pencil familiarly with his left hand, yet, as it is ſo unuſual, it muſt have had but an unſeemly and aukward appearance in a picture; which probably might have been his real inducement for repreſenting himſelf without ſuch a particularity. Beſides, the writer of Holbein's life, at the end of the treatiſe by De Piles, mentions a print by Hollar, ſtill extant, which deſcribes Holbein drawing with his left hand. Nor is it ſo extraordinary or incredible a circumſtance; for other artiſts, mentioned in this volume, are remarked for the very ſame habit; particularly Mozzo of Antwerp, who worked with the left; and Amico Aſpertino, as well as Ludovico Cangiagio, who worked equally well with both hands.

The genius and excellence of this maſter were ſufficiently ſhewn in the hiſtorical ſtyle, by two celebrated compoſitions which he painted in the hall of the Steel-yard company; and they were univerſally admired for the richneſs of the colouring, as alſo for the ſtrong character in the figures through the whole. Zucchero, on ſeeing thoſe pictures, expreſſed the higheſt eſteem for Holbein, and even copied them in Indian ink.

Holbein undoubtedly had many excellencies, which procured him, very deſervedly, the admiration of all Europe; but to equal him in portrait with Raphael and Titian, as Zucchero did, or to place him on an equality with the beſt of Raphael's diſciples in compoſition, as Abbé du Bos has done, ſeems to be not altogether juſtifiable; for, notwithſtanding the abundant merit of this maſter in many reſpects, it cannot be denied that the German taſte predominates through moſt, if not all, of his compoſitions.

It is indeed to be lamented, that ſuch a number of pictures are poſitively aſſerted to be of the hand of Holbein, which are a diſhonour to his pencil; but any judicious perſon, who hath obſerved one genuine picture, will not eaſily be impoſed on.

In the Florentine collection are the portraits of Holbein, Luther, ſir Thomas More, and Richard Southwell, all painted by this maſter; and in the cabinet of the king of France, beſides ſeveral portraits, there is an hiſtorical ſubject by Holbein, repreſenting the "Sacrifice of Abraham," which is accounted a fine performance. He died in 1554, aged 56.

HOLBORNE Isle, in *Geography*, a ſmall iſland near the N.E. coaſt of New Holland; 20 miles N.W. of cape Glouceſter.

HOLBERG, Louis, *Baron Von*, in *Biography*, a celebrated Daniſh writer, was born at Bergen, in Norway, about the year 1685. Owing to the early death of his parents, who had brought up a numerous family very reſpectably, he firſt went into the army, and then diſcovering an attachment to learning, he was put under the care of a private tutor by a near relation. The ſtraightneſs of his own, and likewiſe of his friends' circumſtances, was the cauſe of the many viciſſitudes which he experienced before he had attained to man's eſtate. At length he completed his ſtudies at Copenhagen, and then returned to his native place, where he became private tutor in the family of the ſuffragan of the biſhop of Bergen. His temper was ill adapted to the ſituation, and in a few weeks he collected what money he was able to procure and ſet off for Holland. His reſources were ſoon exhauſted, and he was glad to return, directing his courſe to Chriſtianſand, where he obtained a living by teaching the languages. After this he went to England; and at Oxford his ſkill in muſic and the learned tongues obtained for him many pupils. His love of change had hitherto kept him in a ſtate of poverty, and though he had many good offers, ſome of which he accepted, yet he never ſtaid long enough in one place to benefit by them. He dedicated his "Introduction to the Modern Hiſtory of France" to Frederic IV. which procured for him the place of an extraordinary profeſſor at Copenhagen, which he had a very ſhort time, when he travelled, by the way of the Netherlands, into France. After a conſiderable ſtay at Paris he went to Rome, where he ſpent a winter, and then returned to the French capital by way of Florence, Bologna, Turin, and Lyons. He next went to Copenhagen, where he publiſhed, in the Daniſh language, "An Introduction to the Law of Nature and Nations." After this he obtained an appointment which raiſed him above poverty, being made profeſſor of metaphyſics, though, according to his own account of the matter, it was one of the ſubjects with which he was leaſt acquainted. This promotion was followed by a place in the conſiſtory, which gave him a higher rank, and made a farther addition to his income. His reputation as a writer being eſtabliſhed, he frequently appeared before the world as an author, and in 1735 he became rector of the univerſity of Copenhagen, and in two years after he was entruſted with the management of its finances. While at the head of the univerſity, he exerted himſelf to promote the intereſts of learning, and gave prizes to thoſe ſtudents who excelled in the different branches of literature. He was a ſucceſsful author, and obtaining much property by his literary labours, he purchaſed an eſtate in Iceland, and at his death, which happened in 1754, he bequeathed a large ſum of money to the academy of Soroe in Iceland, for the purpoſe of educating young nobility, on which account his memory has been celebrated by an annual oration. He ſettled alſo 16,000 dollars, the intereſt of which was to be employed in providing eſtabliſhments for young women at Copenhagen. Holberg poſſeſſed a ſtrong turn for ſatire and ridicule, of which he gave an admirable ſpecimen in "Klimm's Subterranean Travels, containing a new Theory of the Earth, with a Deſcription of the Fifth Monarchy, which hitherto has been totally unknown." This work has gone through many editions, and been tranſlated into different languages. It is thus deſcribed by one of the tranſlators: "Holberg's acuteneſs in diſcovering the imperfections of moſt governments, the inſtructive manner in which he criticiſes, and which evidently diſplay a philoſophical mind and depth of judgment; his accurate ſpirit of obſervation; his lively ridicule which, for the moſt part, is under the veil of philanthropy and naiveté, together with the elegance of the ſtyle, not only obtained a favourable reception to this work on its firſt appearance, but will ſecure it for ages. On account of the romantic event it records, it may be claſſed with Lucian's "True Hiſtory," or "Gulliver's Travels;" but it exceeds both in variety of matter, as well as in delicacy of ſatire. Lucian only laughs, and Swift is too bitter, whereas Holberg ſteers a middle courſe between both." In his country baron Holberg is principally known by his "Introduction to Univerſal Hiſtory," which was tranſlated many years ſince by Dr. Gregory Sharpe; and a new edition of this work was given to the public in 1787, by William Radcliffe, A.B. Of the baron Dr. Sharpe ſays, "he was author of many works in proſe and verſe, almoſt all of them written in the Daniſh language. He wrote 25 plays, a metamorphoſis, the reverſe of Ovid's, relating the change of flowers, trees, and animals into men; he was the author of ſeveral ſatires in verſe; of the entertaining voyage under ground of Klimms, in Latin, called *Iter Subterraneum*; of ſome epigrams; of his own life; of an excellent eccleſiaſtical hiſtory; another of the Danes, and one of the Jews, with ſeveral moral, hiſtorical, and other pieces; and he was always infirm and ſtudious, had travelled much, and loved and imitated the manners of the Engliſh." See Dr. Sharpe's preface to the Introduction to Univerſal Hiſtory.

HOLBOURN Head, in *Geography*, a cape of Scotland, on the N. coaſt of the county of Caithneſs. N. lat. 58° 39′. W. long. 3° 20′.

HOLCE, Ὁλκη, a word uſed by ſome of the Greek authors, as the name of a dram weight; and by others, as Dioſcorides, &c. to ſignify a weight in general.

HOLCOMBE, Henry, in *Biography*, was a choriſter in the cathedral of Saliſbury, and having a very fine treble voice, was ſent for up to London, to perform in the firſt attempts at operas on the Italian model. In "Camilla," he performed the part of Preneſto; and being very young at that time, is called, in the printed copy of the muſic, *the boy*. In Roſamond, he performed the part of the page, under the ſame title. His voice breaking, he ſoon after quitted the ſtage, and became a muſic-maſter. He had many ſcholars, particularly in ſinging; for which, from conſtantly frequenting the opera, after he had ceaſed to perform there, and hearing all the great ſingers from Valentini and Nicolini, to Seneſino and Farinelli, he muſt have been well qualified, and we have been aſſured by very good judges, who had often heard him ſing in private, that his taſte was perfectly Italian.

One ſong only of his compoſition, "Happy hours, all hours excelling," is printed in the Muſical Miſcellany.

But his elegant ballad of "Arno's Vale," written on the death of Gaſton, the laſt duke of Tuſcany, of the houſe of Medici, by Charles earl of Middleſex, afterwards duke of Dorſet, and addreſſed to his favourite, the Muſcovita, a ſinger, was afterwards in great favour, and printed in a collection of twelve ſongs ſet by Holcombe, and publiſhed a ſhort time before his death, which happened about the year 1750.

HOLCUS, in *Botany*, a name in Pliny, ὅλκος of the Greeks, and by the ancients underſtood as a kind of wild barley, with awns, growing in dry ſtony places. Profeſſor Martyn deduces it from ὄλκος, *a furrow*, but we do not find this etymology, nor any other that has fallen in our way, ſatisfactory. The name, as applied by Linnæus, embraces a heterogeneous aſſemblage, in which is the *Sorghum* of the ancients; but ſome ſpecies have of late been removed from it; (ſee HIEROCHLOE.) Mr. Brown, in his Prodr. Nov. Holl., wiſhes to confine the genus nearly to that peculiar tribe to which the *Sorghum* belongs, and which is well illuſtrated by Mieg in the *Acta Helvetica*, v. 8. 114. t. 8, this laſt-named author expreſſing a deſire that ſuch might be ſeparated, under the name of *Sorghum*, as a diſtinct genus from the *Holcus* of Linnæus. To this we gladly aſſent, and then perhaps our Engliſh ſpecies, *mollis*, *lanatus*, and *avenaceus*, may ſerve as the baſis of *Holcus*, for we cannot agree with Haller and Mieg to refer the two firſt, any more than the laſt, to *Avena*. In purſuance of this plan, we ſhall for the preſent put aſide *Sorghum*, for the conſideration of ourſelves or our ſucceſſors in its proper place. The following therefore will be the characters and ſynonyms of our *Holcus*. —Sm. Fl. Brit. 88. Engl. Bot. t. 1169, 1170, 813. Schrad. Germ. v. 1. 247, ſection 1. Leers t. 7. f. 6, 7. —Claſs and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two valves, erect, beardleſs, ovate, containing two florets; one of them elevated on a ſtalk. *Cor.* of two valves; the lower or outer one largeſt, awned at the back in the leaſt perfect floret. Nectary a cloven membranous ſcale. *Stam.* Filaments three in each floret, capillary, rather ſhort; anthers long, linear, cloven at each end. *Piſt.* Germen ovate; ſtyles two, capillary, diverging; ſtigmas oblong, feathery. One floret has either no piſtil, or only an imperfect one. *Peric.* none, except the permanent glumes. *Seed* ſolitary, ovate, attached to the hardened corolla.

Eſſ. Ch. Calyx of two valves, two-flowered; one floret with an imperfect germen. Corolla of two valves; the outer one awned.

1. H. *lanatus*. Meadow Soft-graſs. Linn. Sp. Pl. 1485. Curt. Lond. faſc. 4. t. 11. Schreb. Gram. 145. t. 20. f. 1. Sm. Engl. Bot. t. 1169. Knapp. t. 37. Leers. 219. t. 7. f. 6. (Gramen pratenſe paniculatum molle; Scheuchz. Agroſt. 234. t. 4. f. 24, A, B.)—Calyx-glumes woolly. Lower floret beardleſs; upper with an arched recurved awn. Leaves downy on both ſides.—Abundant in meadows and paſtures throughout Europe, eſpecially where the ground is ſandy, flowering in June and July. The *roots* are perennial, fibrous, tufted, not creeping. *Stems* ſeveral, a foot or two in height, ſimple, erect, leafy, jointed, clothed with ſoft, deflexed, denſe hairs. *Leaves* flat, acute, greyiſh, clothed on both ſides, but eſpecially beneath, with ſimilar pubeſcence; the ſheaths of the uppermoſt longeſt and ſwelling. *Stipula* ſhort and blunt. *Panicle* erect, compound, denſe, downy, hoary, moſtly with a purpliſh tinge; its ultimate ſtalks capillary. *Calyx-valves* nearly equal in length, the innermoſt broadeſt. *Florets* not riſing above the calyx; the upper one ſcarcely ever having any piſtil. Its outer glume is blunt, terminating in a ſmall awn, which, when the flowers are arrived at full maturity, is recurved in an arched manner, and is well compared by Scheuchzer to a fiſhing hook. This graſs is mown for hay, along with any others that happen to grow with it, but has not been recommended for particular cultivation.

2. H. *mollis*. Creeping Soft-graſs.—Linn. Sp. Pl. 1485. Curt. Lond. faſc. 5. t. 8. Schreb. Gram. 149. t. 20. f. 2. Sm. Engl. Bot. t. 1170. Knapp. t. 38. Leers. 218. t. 7. f. 7. (Gramen caninum paniculatum molle; Scheuchz. Agroſt. 235. t. 4. f. 25.)—Calyx-glumes partly naked. Lower floret beardleſs; upper with a ſharply-bent awn. Root creeping.—Native of ſhady copſes and hedges, but much leſs frequent than the former, from which it is diſtinguiſhed by its creeping *root*, and the acute angle formed by the awn of the male floret when ripe and dry. It is moreover a more ſlender and leſs downy graſs, with a ſmaller *panicle*, but larger *flowers*, and more prominent awns. It bloſſoms in July, and is conſidered of no value to the huſbandman, but rather noxious, as a kind of couch-graſs. The widely-ſpreading roots are, indeed, in ſome ſituations, difficult of extirpation, but they do not thrive in open land.

3. H. *avenaceus*. Oat-like Soft-graſs. Wiggers. Holſat. 72. Sm. Fl. Brit. 90. Engl. Bot. t. 813. Knapp. t. 39. Schrad. Germ. v. 1. 247. (Avena elatior; Linn. Sp. Pl. 117. Curt. Lond. faſc. 3. t. 6. Mart. Ruſt. t. 7. Leers. 40. t. 10. f. 4.)—Calyx-glumes unequal, ſmooth. Male floret loweſt, with a bent awn. Root knotty.—Common in paſtures, meadows, and waſte ground, flowering in June and July. *Root* perennial, of two knots, or ſwollen joints, one above the other. *Stems* a yard high. *Leaves* darkiſh green, rough and rather harſh. *Stipula* ſhort, abrupt, minutely toothed. *Panicle* half-whorled, the branches conſequently leaning one way. *Flowers* much larger than the two preceding, ſcarioſe, ſhining, not downy. *Anthers* pendulous, purple. The male *floret* has the rudiments of a germen, and is loweſt in this ſpecies, always conſpicuouſly awned; the other is but ſlightly elevated. No uſe is made of this graſs.

Schrader makes a ſpecies, under the name of *H. bulboſus*, of what we conſider as a variety of this, growing in cultivated fields, and thence, if we miſtake not, acquiring rather more bulbs, and downy joints to the ſtem, both circumſtances originating probably from a more expoſed and dry ſtation than is natural to it. Gramen bulboſum nodoſum, Lobel. Ic. v. 1. 23, is conſidered as a repreſentation of this.

H. *laxus* of Linnæus, by his character of the florets, ſhould ſeem to belong to this genus, but its racemoſe habit is very diſſimilar, and the flowers require to be examined by thoſe who have acceſs to them alive. It grows in North America, and has the habit, but not the character, of Michaux's *Feſtuca diandra*, Boreal. Amer. v. 1. 67. t. 10.

H. *ſtriatus*, Linn. is the very ſame thing as his *Panicum curvatum*.

H. *ſerratus*, Linn. Suppl. 433, found at the Cape by Thunberg, is probably of ſome other genus, poſſibly a *Sorghum*. Its ſtrongly ſerrated *leaves* are extremely peculiar.

H. *latifolius*, Linn. Sp. Pl. 1486, is alſo Cenchrus lappaceus of the ſame work, two pages forward. This is an Eaſt Indian graſs, with three or four ſingularly barbed florets in each calyx, quite unlike a genuine *Holcus*, but we cannot inveſtigate its flowers, ſo as to decide, with any certainty, concerning its true genus.

Holcus, in *Agriculture*, the name by which a genus of graſſes is known; but few of the ſpecies of which are found uſeful to the farmer. It ſignifies ſoft graſs.

Holcus *lanatus*, the meadow ſoft graſs, which is ſuppoſed, by Mr. Curtis, to be a very common graſs in all meadows and paſtures, as well as in waſte grounds and woods newly cut down, and which is alſo hardy, as well as productive of foliage, flowering a month later than the *anthoxanthum*, and when its red panicle appears, it is conſidered by the farmers that their graſſes are ready for the ſcythe. Its foliage is ſoft and woolly, which, if not diſliked by cattle on that account, may, it is ſuppoſed, rank with ſome of the beſt graſſes; if it were more curly, it would, however, be more valuable. It is not, however, thought ſo well of by Mr. Sole; as from its particular ſoftneſs, he cannot conceive it excellent either as a paſture or hay graſs. It is the graſs which is uſually known to farmers in this country by the name of Yorkſhire-white.

Holcus *mollis*, the name by which the creeping ſoft graſs is known. It has been ſuggeſted by Mr. Curtis in his "Tract on Graſſes," that he is induced to think better of it now, than when he figured and deſcribed it in his "Flora Londinenſis," having found that it will grow well in a ſandy ſoil, and bear the drought of ſummer, better than moſt others. And it is added that captain Dorſet is of opinion that it may even be cultivated to advantage in ſoils of the barren ſandy kind.

HOLD, in the *Manege*. See Retain.

Hold, in *Rural Economy*, a term applied to female animals, which after being covered or connected with the males, without miſcarrying, are ſaid to hold.

Hold, *of a ſhip*, the loweſt part of the ſhip, including all that part of her inſide lying between the floor and the lower deck, through her whole length.

The hold is the ſtore-room in a merchant ſhip, or the place wherein the goods, at leaſt all the heavier and more cumberſome, are ſtowed: the reſt are diſpoſed between the two decks; at leaſt in Dutch ſhips, which have their holds very ſhallow, and the ſpace between the decks very high. The hold contains the ballaſt, proviſions, and ſtores, of a ſhip of war. The ſeveral ſtore-rooms are ſeparated by bulk heads, and are denominated according to the ſeveral articles they contain, the ſail-room, the bread-room, the fiſh-room, the ſpirit-room, &c.

To find the burden of a ſhip, the hold is to be meaſured.

Hold, in *Sea Language*, is underſtood to ſignify a particular ſituation with regard to the ſhore, by which ſhe is enabled to keep within a ſufficient diſtance, to facilitate her courſe, or anſwer ſome other important object. *Keep a good hold of the land*, implies to keep near, or in ſight of the land.

Hold, *after*, denotes that part of the hold which lies abaft the main-maſt.

Hold, *fore*, is that part of the hold which is ſituated in the fore-part of the ſhip, or before the main hatchway.

Hold *its own*, at *Sea*. A ſhip is ſaid to hold its own, that keeps her courſe right forward.

Hold, *to rummage the*, is to remove and clear the goods and things therein.

Hold, *predy the*, in the *Sea Language*. See Predy.

Hold, *to trim the*. See Trim.

Hold, *ſtowing the*, a ſea-phraſe for taking goods into the hold. See Stowage.

Hold, in *Muſic*, is a mark, like an arch, with a point in the middle of it, placed over ſome ſingle notes, which has been uſed to ſignify that ſuch note is to be made longer than ordinary; but it now more commonly denotes that the ſong ends there, and is only uſed when the ſong ends with a repetition of the firſt ſtrain, or part of it.

HOLDE, in our *Old Law Books*, is uſed for the bailiff of a city or town: and ſometimes for a general.

Holden, in *Geography*, a townſhip of America, in Worceſter county, Maſſachuſetts, ſeven miles N. of Worceſter, and 51 W. of Boſton; containing 1142 inhabitants.

Holden, John, in *Biography*, author of an excellent eſſay towards a rational ſyſtem of muſic.

We are unable to give a biographical account of this ingenious author; but his work, which was publiſhed at Glaſgow, in long quarto, half bound, in 1770, ſeems to have been much leſs noticed by the public than it deſerves. Its principles are good, and explained in clear and correct language. Without diſcovering a marked partiality for ancient or modern muſic, or an excluſive predilection for the productions of any particular country or individual, he has endeavoured, and we think with conſiderable ſucceſs, to explain the materials with which good compoſitions are built; and, without pedantry or fantaſtical innovations, has ranged through the wide extended regions of the art. We will not ſay that this little treatiſe (in ſize) renders all other books on the ſubject unneceſſary, or that the author has left nothing for ſubſequent writers to do. No; all we mean to ſay is, that what he *has* done, is *well* done; but if his work had been much more voluminous than it is, much muſt have been left for ingenious, intelligent, and ſpeculative writers to ſay on the ſubject, and during the lapſe of more than 30 years, ſince this book appeared, ſuch a rapid progreſs has been made in the theory and practice of the art, that Mr. Holden, if ſtill an inhabitant of earth, might fill a ſecond volume of his work by deſcribing, the new paſſages and effects in the works of Haydn and Mozart alone, that have delighted the lovers of muſic, ſince the publication of his firſt volume.

The author, in Part I., has treated with clearneſs and ingenuity the following ſubjects:

Of the natural ſcale, 26 ſections.
Application of the ſcale, 9 do.
Of the modern ſyſtem of muſic, 22 do.
Of time, 45 do.
Miſcellaneous explanations, 15 do.
Harmonical conſonances, 26 do.
Of diſſonances.
Of fundamental progreſſions.
Of the flat ſeries.
Of chromatic.
Of plain diſcant.
Figurative melody.

Part II.

Of the theory of muſic (ſound).
Single muſical ſounds.
Of muſical ſounds in ſucceſſion.
Of harmonical arithmetic (ratios).
Of combined ſounds.

This author is no ſervile follower of any preceding writer: his precepts ſeem to ariſe from experience and reflection.

His calling the pauſe and final mark, N° 101, a *hold*, is not a term in uſe at preſent. The Italian term for it is *corona*, or crown. It is, ſometimes, colloquially called in England a *bull's eye*; but it is vulgar ⊙ 𝄐

Indeed, in theſe chapters we have a muſical dictionary, or technica: rules for thorough baſe: harmonics, and many other things, which the titles of the chapters do not promiſe.

There is in this work no parade of great reading, or knowledge of languages; yet we perceive that the author is not unacquainted with Zarlino, Rameau, d'Alembert, Rouſſeau, and Serre of Geneva.

In the plate facing p. 76, he calls C, with a $^{6}_{5}$ in the key of G, a fundamental baſe; but the fundamental baſe to that chord as 4th of the key, is A with a 7th, and the author ſeems to be not perfectly familiariſed to Rameau's *baſſe fondamentale.*

The plate facing p. 100, is a bad ſpecimen of his abilities in compoſition. The repeating the ſame harmony to the firſt note of a new bar, as had been given to the laſt note of the preceding bar, will always be found inſipid, and what is conſtantly avoided by contrapuntiſts of the firſt claſs.

He gives us inſtances of his harmony, but none of his melody; except ſuch as are pſalmodic.

But melody is very hard to teach. Keeping good company, that is, frequently hearing good muſic, forms the taſte, and ſtimulates invention. A man that hears nothing but pſalmody and national tunes, will never produce graceful and elegant melody, or great effects in harmony.

HOLDEN's *Temperament of the Muſical Scale.* In Mr. John Holden's "Eſſay towards a Rational Syſtem of Muſic," he recommends a ſyſtem of tuning common-keyed inſtruments, in which the ſeries of eight 5ths C, G, D, A, E, B ※F, ※C and ※G upwards are each flattened $\frac{1}{5}$th of a major comma, and the three 5ths *c*, F, ♭B, and ♭E downwards, are alſo flattened $\frac{1}{5}$ *c*, leaving a wolf or bearing 5th between ※G and ♭E. Mr. Farey, in the 5th Scholium to his Muſical Theorems, in the Phil. Mag. vol. xxxvi. p. 46, ſhews, that in this regular douzeave, the fifths are as much tempered flat as the major thirds are ſharp (not *flat* as printed), and whence we obtain the fifth's temperament = 2.20157 Σ flat, the Vth wolf = 12.20944 Σ, the IIId temperaments 2.20157 Σ ſharp, the IIId wolves = 16.61258 ſharp, the VIth temperaments = 4.40314 Σ ſharp, and the VIth wolves = 18.81316 Σ ſharp. Only three of the fifths, *viz.* between C※, G※, ♭E, and ♭B in this ſyſtem, differ from thoſe in Mr. HAWKE's *Douzeave Syſtem,* ſee that article.

At pages 338 and 364 of the work above quoted, Mr. Holden, proceeding on the miſtaken principles to which we have adverted in our article GRAVE, *Harmonics,* gives an aſcending and a deſcending ſcale of intervals, which, when combined and reduced to one fundamental, ſtand as follows: *viz.*

		Σ	f	m
c	$\frac{1}{2}$	612	+ 12	+ 53
	$\frac{32}{63}$	598.0528	+ 12	+ 52
B	$\frac{21}{40}$	568.9472	+ 11	+ 49
	$\frac{8}{15}$	555	+ 11	+ 48
♭B	$\frac{4}{7}$	494.0528	+ 10	+ 43
A	$\frac{7}{12}$	475.9472	+ 9	+ 41
	$\frac{16}{27}$	462	+ 9	+ 40
	$\frac{3}{5}$	451	+ 9	+ 39
※G	$\frac{63}{100}$	407.9472	+ 8	+ 35
	$\frac{16}{25}$	394	+ 8	+ 34
G	$\frac{21}{32}$	371.9472	+ 7	+ 32
	$\frac{2}{3}$	358	+ 7	+ 31
※F	$\frac{7}{10}$	314.9472	+ 6	+ 27
	$\frac{32}{45}$	301	+ 6	+ 26
F	$\frac{3}{4}$	254	+ 5	+ 22
	$\frac{16}{21}$	240.0528	+ 5	+ 21
E	$\frac{7}{9}$	221.9472	+ 4	+ 19
	$\frac{64}{81}$	208	+ 4	+ 18
	$\frac{4}{5}$	197	+ 4	+ 17
♭E	$\frac{21}{25}$	153.9472	+ 3	+ 13
	$\frac{64}{75}$	140	+ 3	+ 12
D	$\frac{7}{8}$	117.9472	+ 2	+ 10
	$\frac{8}{9}$	104	+ 2	+ 9
※C	$\frac{24}{25}$	36	+ 1	+ 3
C	$\frac{1}{1}$			

By the decimal fractions of ſchiſmas (Σ) in the third column, it will appear, which of theſe ratios involve the number 7, which does not belong to the diatonic ſyſtem, amounting to nearly one-half of the whole number of notes, with which this fanciful ſyſtem is encumbered.

HOLDER, WILLIAM, in *Biography,* doctor of divinity, canon of Ely, reſidentiary of St. Paul's, and ſub-dean of the Chapel Royal, not only merits particular notice as an able and learned writer on the theory of muſic, but as an eccleſiaſtical compoſer of anthems, of which three or four are preſerved in Dr. Tudway's collection, Britiſh Muſeum. From the regularity and unembarraſſed arrangement of the ſeveral parts in theſe ſpecimens of his compoſition, it is eaſy to diſcover, that he had not ſtudied and practiſed counterpoint in the ſuperficial manner of an idle dilettante, but with the application of a diligent profeſſor.

Beſides his eminence as a divine, and deep knowledge in muſic, he diſtinguiſhed himſelf as a philoſopher, a mathematician, and a philologer. He was one of the firſt fellows of the Royal Society, and in treating ſeveral curious ſubjects, nice ſelection and application of words manifeſt him to have been a conſummate maſter of our language. Indeed, the ſtrength, preciſion, clearneſs, and compreſſion of his ſtyle have been hardly ever equalled by any writer on philoſophical ſubjects in our country; particularly in his admirable treatiſe on the "Elements of Speech," publiſhed 1669, and drawn up with the benevolent deſign of giving relief to a perſon that was deaf and dumb. In this eſſay he has analyſed, diſſected, and claſſed the letters of our alphabet ſo minutely and clearly, that it is well worthy the attentive peruſal of every lover of philology, but particularly of lyric poets and compoſers of vocal muſic; to whom it will point out ſuch harſh and untunable combinations of letters and ſyllables as from their difficult utterance impede and corrupt the voice in its paſſage.

In 1694, Dr. Holder publiſhed "A Diſcourſe concerning Time," in which, among other things, the deficiency of the Julian Calendar was explained, and the method of reforming it demonſtrated, which was afterwards adopted in the change of ſtyle. It is to be lamented that in treating this ſubject with ſo much clearneſs and ability, ſo good a muſician did not extend his reflections on the artificial parts of time, to its diviſions and proportions in muſical meaſures; a ſubject upon which the abbate Sacchi has written in Italian, "Del Tempo nella Muſica;" but which rhythmically, or metrically conſidered in common with poetry, has not yet been ſufficiently diſcuſſed in our own language.

The ſame year was publiſhed by Dr. Holder, "A Treatiſe on the Natural Grounds of Harmony," in which the propagation of ſound, the ratio of vibrations, their coincidence in forming conſonance, ſympathetic reſonance, or *ſons harmoniques*, the difference between arithmetical, geometrical, and harmonic proportions, and the author's opinion concerning the muſic of the ancients, to whom he denies the uſe of harmony, or muſic in parts, are all ſo ably treated, and clearly explained, that this book may be read with profit and pleaſure by moſt practical muſicians, though unacquainted with geometry, mathematics, and harmonics, or the philoſophy of ſound. This book is ſaid, in the introduction, to have been drawn up chiefly for the ſake and ſervice of the gentlemen of the chapel royal, of which he was ſubdean, and in which, as well as other cathedrals to which his power extended, he is ſaid to have been a ſevere diſciplinarian; for being ſo excellent a judge and compoſer himſelf, it is natural to ſuppoſe that he would be the leſs likely to tolerate neglect and ignorance in the performance of the choral ſervice. Michael Wiſe, who perhaps had fallen under his laſh, uſed to call him Mr. *Snub*-dean.

Dr. Holder died in 1696, aged 82, and was buried in the ſubterraneous chapel of St. Paul's church, where a marble monument is erected to his memory, with an inſcription reciting his titles, talents, and extenſive knowledge.

HOLDERNESS, in *Geography*, a townſhip of America, in Grafton county, New Hampſhire, on the E. ſide of Pemigewaſſet river, incorporated in 1761, and containing 531 inhabitants; 64 miles N.N.W. of Portſmouth.

HOLD-FAST, an iron hook, in ſhape of the letter S, fixed in a wall, to retain and ſupport it.

This term alſo denotes a tool uſed by joiners, &c., which goes through their benches, to hold faſt ſuch work as cannot be finiſhed by being held in the hand.

HOLDING ON, in *Sea Language*, is the act of pulling back the hind-part of any cable, or other rope, which is heaved round by the capſtan or windlaſs, or drawn in by the purchaſe of a tackle. As there are only a few turns of any rope above the barrel of the capſtan or windlaſs when it is employed, in heaving, an equal quantity of the rope will neceſſarily come off from the capſtan at the ſame time; and this is accordingly pulled back as ſtrongly as poſſible to prevent it from ſurging or jerking round the barrel, by being held too looſely; ſo that holding-on denotes the act of retaining any quantity of rope acquired by the effort of a capſtan, windlaſs, or tackle, as theſe are employed in hoiſting as well as in heaving.

Holding *water* ſignifies the operation of ſtopping a boat in her courſe, by holding the oars in the water, and bearing the blade or flat part ſtrongly againſt the current made alongſide, by her paſſing ſwiftly through the water.

Holding *over a term*, &c., in *Law*. By 4 Geo. II. cap. 28. in caſe any tenant for life or years, or other perſon claiming under or by colluſion with ſuch tenant, ſhall wilfully *hold over* after the determination of the term, and demand made and notice in writing for recovering the poſſeſſion of the premiſes, by him to whom the remainder or reverſion ſhall belong; ſuch perſon ſo holding over, ſhall pay for the time he continues at the rate of double the yearly value of the lands ſo detained. See Ejectment and Treſpass.

HOLDSWORTHY, in *Geography*, a ſmall market town and pariſh in the hundred of Black Torrington, Devonſhire, England, is ſituated near the weſtern borders of the county, between two ſmall ſtreams, which fall into the river Tamar, at a ſmall diſtance. In the year 1801, this town was returned to parliament as containing 204 houſes, and 1045 inhabitants: the chief employment of the latter is derived from the operations of agriculture. Holdſworthy is 214 miles W. from London; has a weekly market on Saturdays, and three annual fairs. Polwhele's Hiſtory and Antiquities of Devonſhire.

HOLE, in *Anatomy*, denotes ſuch a cavity of a bone as penetrates from one ſide to the other.

Hole, *Black*, *at Calcutta*, denotes a place of confinement, eighteen feet by eighteen feet, containing three hundred and twenty-four ſquare feet, in which a hundred and forty-ſix perſons were ſhut up by order of the viceroy: ſo that there was a ſquare for each perſon of twenty-ſix inches and a half by twelve inches, which was juſt ſufficient to hold them, without preſſing violently upon each other. To this dungeon there was only one ſmall grated window; and the weather being very ſultry, the air within could neither circulate nor be changed. In leſs than an hour after their being incloſed, many of the unhappy people were ſeized with extreme difficulty of breathing, ſeveral were delirious, and the place was filled with incoherent ravings and exclamations of diſtreſs; the cry of *water! water!* was predominant. This was handed to them by the centinels, but had no effect in allaying their thirſt. In leſs than four hours, many were ſuffocated, or died in violent deliriums. In an hour more, the ſurvivors, except a few at the grate, were to the higheſt degree phrenitic and outrageous. At length thoſe at the grate became ſo inſenſible, that we have no account of what happened, till they were releaſed at ſix o'clock next morning, having been confined from ſeven the preceding evening. Such were the effects of animal effluvia in a cloſe and unventilated place, in the ſpace of eleven hours, that out of a hundred and forty-ſix perſons, no more than twenty-three came out alive, and thoſe in a high putrid fever, of which, however, by freſh air, &c. they gradually recovered.

Hole, in *Geography*, a town of Norway, in the dioceſe Aggerhuus; 15 miles N.W. of Chriſtiania.

Hole *town*, a town on the W. coaſt of the iſland of Barbadoes. N. lat. 13° 12'. W. long. 58° 31'.

Hole, in *Mining*, ſignifies the act of holeing, clearing, kiving, curving, under-going, or under-mining the face or bank of coal in a coal-pit, preparatory to its being fell or wedged down, the proceſſes of which will be found in Mr. Farey's Report on Derbyſhire, vol. i.

HOLEING, ſignifies the under-mining or looſening of coals in a pit. See Hole.

Holeing-*ſtuff*, ſignifies the ſmall earth or coals which is cut or picked out from under the coal in a pit: the ſmall coals thus obtained are ſometimes holeing-coal, ſleck, &c.

HOLEN, in *Geography*, a town of Norway, in the dioceſe of Aggerhuus; 18 miles from Tonſberg.

HOLENECK, a town of the duchy of Stiria; 10 miles S. of Voitſberg.

HOLERS, in *Mining*, are a ſet of colliers, whoſe buſineſs it is, during the night, where coals are worked the long way, to hole, or undermine the banks or face of coal, ready for the next day's work.

HOLESCHAU, or Holessow, in *Geography*, a town of Moravia, in the circle of Prerau; 20 miles S. E. of Olmutz. N. lat. 49° 18'. E. long. 17° 32'.

HOLIBUT, or Holybut, in *Ichthyology*, a name given by the people of ſome parts of England to the turbot in general; but in other parts only to the larger fiſhes of that ſpecies. See Pleuronectes *Hypogloſſus*.

HOLINGSHED, Ralph, in *Biography*, an Engliſh chronicler, deſcended from a family ſettled at Boſely in Cheſhire, was educated at Cambridge, where he is ſaid to have taken his degree of M. A. in 1544. He lived in ſome capacity, probably as ſteward, with Thomas Burdett, eſq., of Bromcote in Warwickſhire, at which place he died about the year 1580. Holingſhed has given name to a compilation of Engliſh hiſtory from the earlieſt periods, of which the firſt edition was publiſhed at London in 1577, in two volumes folio. The ſecond edition was publiſhed ten years after, and brought down the hiſtory to the preceding year. Holingſhed was employed by Reginald Wolfe, printer to the queen; and he was aſſiſted by ſeveral other perſons, and upon his death it was continued by John Stowe. Very conſiderable retrenchments from the firſt edition were made in the ſecond and third, of thoſe parts which were not agreeable to Elizabeth and her miniſters, by order of the privy council. Amidſt the tediouſneſs and vulgarity of theſe chronicles many facts are to be found, highly uſeful in elucidating the manners and cuſtoms of the more early periods. Biog. Brit.

HOLISTHEMA, in *Surgery*, a diſlocation.

HOLITZ, in *Geography*, a town of Hungary; 32 miles W.N.W. of Topoltzen.—Alſo, a town of Bohemia, in the circle of Chrudim; 10 miles N. E. of Chrudim.

HOLKABERG, a town of Sweden, in Eaſt Gothland; 35 miles S.W. of Linkioping.

HOLL, a word which is provincially employed to ſignify the hollow of a ditch, in contradiſtinction to the dick or bank of it.

HOLLAND, Philemon, in *Biography*, was born at Chelmsford, in Eſſex, about the year 1551; and after receiving the rudiments of learning at the grammar-ſchool of that place, was ſent to Trinity college, Cambridge, of which he became fellow, and left the univerſity after having taken the degree of M. A. He was appointed head maſter of the free-ſchool of Coventry, where he had ſettled; and in this laborious ſtation he not only attended aſſiduouſly to the duties of his office, but ſerved the intereſts of learning, by undertaking thoſe numerous tranſlations, which gained him the title of *Tranſlator general of the age*. But, as if theſe occupations were inſufficient for the employment of his time, he likewiſe turned his ſtudies to medicine, and practiſed in that profeſſion with conſiderable reputation in his neighbourhood; and at length, rather late in life, he became a doctor of phyſic, in the univerſity of Cambridge. He was an amiable man in all the relations of private life, and by his habits of temperance and regularity attained his 85th year, not only with the full poſſeſſion of his intellects, but with his ſight ſo good, notwithſtanding his inceſſant uſe of it, that he never had occaſion to wear ſpectacles. He continued to tranſlate till his 80th year; and his tranſlations, though devoid of elegance, are accounted faithful and accurate; and afford a memorable proof, how much a ſingle man may perform, if his whole time be employed to advantage. He tranſlated into Engliſh “Livy,” “Pliny's Natural Hiſtory,” “Plutarch's Morals,” “Suetonius,” “Ammianus Marcellinus,” “Zenophon's Cyropædia,” and “Camden's Britannia,” to the laſt of which he made ſeveral uſeful additions: and into Latin he tranſlated the geographical part of “Speed's Theatre of Great Britain,” and a French “Pharmacopœia of Brice Bauderon.” A quibbling epigram upon his tranſlation of Suetonius has often been retailed in jeſt books.

“Philemon with tranſlations ſo does fill us,
He will not let *Suetonius* be *Tranquillus*.”

See Aikin Biog. Mem. of Medicine.

Holland, in *Commerce*, a fine, white, even, cloſe kind of linen cloth, chiefly uſed for ſhirts, ſheets, &c.

It is principally wrought in the provinces of Holland, Friſeland, and other parts of the United Provinces; whence the appellation.

The principal mart or ſtaple of this cloth is at Haerlem, whither it is ſent from moſt other parts, as ſoon as wove, there to be whitened in the enſuing ſpring.

That manufactured in Friſeland is the moſt eſteemed, and called Friſe Holland. It is the ſtrongeſt and the beſt coloured of any of that fineneſs: it is never calendered, nor thickened, as the reſt; but it is imported juſt as it comes from the whitſter: it is diſtinguiſhed by its being yard quarter and half wide; which is half a quarter more than thoſe commonly called Friſe Hollands, which are not right.

Holland, *gulix*, is very white and fine, and is chiefly uſed for ſhirts, being the ſtrongeſt of any for its fineneſs, except true Friſe. It is juſt yard wide.

Holland, *Alcmaer*, is a very ſtrong cloth, and wears exceeding well. It is about yard quarter and half wide.

Holland, in *Geography*, an appellation applied to the Seven United Provinces collectively, *viz.* Guelderland, Holland, Zealand, Utrecht, Overyſſel, Groningen, and Frieſland (which ſee), but primarily belonging to the chief of them. This country, once a celebrated republic, derives its name from the German word “Hohl,” ſynonymous with the Engliſh term hollow, and denoting a concave or very low country. The people are called Dutch, from the German “Deutſch,” or “Teutſch;” but “Deutſchland” properly ſignifies the vaſt extent of Germany itſelf, though by the Engliſh reſtricted to a ſmall portion, uſing a dialect of the German language. Theſe provinces extend from the north of Groningen to the ſouthern boundary along Auſtrian Flanders and Brabant, about 150 Britiſh miles; and in breadth, from the North ſea to the kingdom of Weſtphalia, about 100 Britiſh miles. Their content, in ſquare miles, is eſtimated at 10,000. They form a kind of peninſula, which is divided into N. and S. Holland; the former including all to the N. of Amſterdam, and the latter extending from the ſtates of Zealand and Brabant to the river Ye. The population has been recently computed at 2,758,632, which, allowing the extent of territory in ſquare miles to be 10,000, will give 275 for each ſquare mile. After the diſmemberment the French accounts ſtate the population at 1,881,881. That of Holland, the chief province, has been calculated at 980,000. The country is low and marſhy; ſome part of it being lower than the ſea, from the inundation of which it is ſecured by dykes or dams; and the meadows, which are covered with water in the winter, are freed from it by means of mills, that are contrived for diſcharging it into the ditches and canals. Without theſe ditches and canals, ſerving as drains to the country, the ſoil would in moſt parts be incapable of cultivation. Among the marſhes that deform the general face of the country, the traveller obſerves numerous and important cities and towns with admiration, and not without very honourable ideas of the aſtoniſhing powers of active induſtry, which have formed a habitable and enviable abode amidſt the greateſt natural diſadvantages. The marſhes, moraſſes, and heaths, which are characteriſtic of the different provinces, are however intermixed with groves, gardens, and meadows. Though the general aſpect of the country preſents an intimate combination of land and water, with few hills and woods, but rather moderate elevations conſiſting of barren ſand, Holland furniſhes little ſcope for the operations of agriculture, the land being moſtly appropriated to paſturage, excepting that ſmall portion of it which is aſſigned to the culture of madder and tobacco. In the province of Guelderland, and the barony of Breda, the waſte grounds are extenſive, being over-run with broom and heath, and the ſoil being generally a black ſand. In the north of Holland, and in Frieſland (which ſee), the paſtures ſupply ſuch a quantity of good butter as to form a ſtaple article of commerce. The chief rivers of the United Provinces are the Rhine, and the Meuſe or Maas, which ſee reſpectively. The lakes are few and of ſmall extent, if we except that which is called the ſea of Haerlem, on the north of which is the Ye, a broad piece of water, reſembling a creek of the ſea rather than a river, which paſſes by Amſterdam. This country has neither mountains nor elevated wood-lands, nor mines; its horſes are chiefly procured from England and Flanders, and for its cows and oxen it is primarily indebted to Holſtein. Fiſh abound on its ſhores, and particularly turbot and ſoals; but its herrings are chiefly obtained from the Northern ocean, by way of the port of Flardingen, or Vlaerdingen, W. of Rotterdam. The climate of this country is cold and humid, and therefore the dreſs of the inhabitants is calculated more for warmth than elegance; the houſes and ſtreets, both in the towns and villages, are diſtinguiſhed by their cleanlineſs and neatneſs, and form a contraſt to the ſqualid appearance of the German villages. The temperament of the Dutch is phlegmatic; and they are characteriſed by labour and perſeverance rather than ardent and impetuous activity. Their ruling paſſion is the love of money. To ſuch a degree does this paſſion prevail, if we may credit the report of a female traveller (Mrs. Radcliffe), that "the infatuation of loving money, not as a mean but an end, is paramount in the mind of almoſt every Dutchman, whatever may be his other diſpoſitions and qualities; the addiction to it is fervent, inveterate, invincible, and univerſal, from youth to the feebleſt old age." In ſtature the Dutch are low, and the women are commonly taller than the men; and notwithſtanding the predominant paſſion of the country, the ancient female affection for gold and jewels is not yet eradicated. The moiſture of the climate leads to the uſe of high-ſeaſoned food, and of ſpirituous liquors. Beſides the uſual games, the chief amuſements of the Dutch, in the days of their proſperity and wealth, were the theatres and the tea-gardens. The opulent merchants took delight in their villas, which were thickly planted among the numerous canals; and though their gardens were ſmall, they were richly ſtored with tulips, hyacinths, and other flowers of immenſe value. In winter ſhooting was a favourite paſtime; and the canals were crowded with people of all ranks. Others, however, whoſe means could afford it, amuſed themſelves under the domeſtic roof, amidſt their expenſive collections of pictures and prints, which they contrived to render a lucrative article of commerce. The Dutch canals of the United Provinces, which are not leſs numerous than the roads in other countries, have been a means of commercial intercourſe as well as of perſonal amuſement, as they have ſerved to augment their inland trade when their foreign commerce has declined, till late meaſures of the ſtate, carried into effect by the ruler of the continent, have been no leſs injurious to them than to their neighbours. The chief manufactures of Holland are linens, pottery, and painted tyles; leather, wax, ſnuff, ſtarch, paper, and alſo ſome articles of woollen, cotton, and ſilk. In a period of national proſperity and opulence, when their colonies were numerous on the coaſt of Hindooſtan, in Ceylon, at Batavia, and at the Cape of Good Hope, &c. and their maritime power very conſiderable, the moſt valuable branch of their commerce conſiſted in ſpices and drugs, brought from their ſettlements in the Eaſt Indies. Their fiſhery in the northern ſeas, and on our coaſts as well as their own, was an object of importance. At a later period they have derived no ſmall advantage from being the grand depoſit of commerce between Great Britain and the Continent; but this intercourſe is for the preſent interrupted; and more eſpecially their inland trade with Germany and France, by the canals and Rhine. One of the moſt profitable articles of this trade conſiſted in the vaſt floats of timber which arrived at Dort, from Andernach and other places on the Rhine, and from the German foreſts. The length of theſe rafts is from 700 to 1000 feet, and the breadth from 50 to 90, and the floating iſland was directed by 500 labourers; and it is ſaid, by the female traveller already cited, that the ſale of one raft, on its arrival at Dort, occupied ſeveral months, and frequently produced more than 30,000*l.* ſterling. The Dutch language is a dialect of the German; and the literature of the United Provinces has ſuſtained an honourable rank. Among thoſe who have contributed to its reputation in this reſpect we may mention Eraſmus, Johannes Secundus, or Hans de Twede, Grotius, Boerhaave, Paul Merula, Adrian Junius, Meurſius, Douſa, Heinſius, the Younger Voſſius, and Hoogeveen of Leyden, who died in 1794, after having acquired the reputation of being the firſt Greek ſcholar in Europe. The largeſt and moſt celebrated Latin ſchools in this country were thoſe at Rotterdam, Breda, Middleburg, Groningen, &c.; and its five univerſities are thoſe at Leyden, Utrecht, Harderwyck, Franeker, and Groningen, beſides two inferior colleges at Amſterdam and Deventer. At Haerlem there is an academy of ſciences.

The Proteſtant religion, in the Calviniſtic form, prevails through the United Provinces; and the treaty of Union, in 1579, provided for its perpetuity. In 1583, indeed, the ſtates of Holland propoſed, that no other form ſhould be tolerated; but this reſolution was wiſely rejected; and every religion is permitted, on condition that it does not oppoſe the fundamental laws, or teach any doctrines that are ſubverſive of the ſtate; but employments of any conſequence are reſtricted to Proteſtants. The eccleſiaſtical ſtate is compoſed of four ranks, *viz.* profeſſors at univerſities, preachers, elders, and deacons; and the government of the church is adminiſtered by conſiſtories, claſſes, and ſynods. The conſiſtory is the loweſt court, commonly conſiſting of the clergy and elders of a particular town; while a claſs conſiſts of deputies from ſeveral, and is commonly aſſembled three times in the year; a part of its duty being to viſit the churches, and watch over the conduct of the clergy. The ſynods are either provincial or national; the firſt being aſſembled every year, while the national ſynod is only ſummoned on the moſt important occaſions, when eſſential doctrines are to be diſcuſſed; and the laſt of theſe was that of Dort in 1618. The provincial ſynods are 53 in number, and conſiſt of 1570 preachers. There are alſo many Walloon churches diſperſed through the provinces, who hold a kind of ſynod twice a year, compoſed of deputies from their own ſect. The Roman Catholics are ſuppoſed to have 350 churches, ſerved by 400 prieſts. The other chief ſects are Lutherans, Remonſtrants, or Arminians, who have 43 teachers, Anabaptiſts, Jews, and a few Quakers.

As to the political hiſtory of the United Provinces, we may obſerve, that the original population of this country appears to have been Celtic; but when the Romans conquered the country, it was occupied by the Batavi, the moſt northern people of Belgic Gaul, ſuppoſed to be a German or Gothic progeny. (See BATAVI.) The Friſians, the next people adjoining to the Batavi on the N., extended themſelves in the ſeventh century down to the Scheldt. In the eighth century the Friſians were ſubdued by the Franks under Charles Martel; but both the Friſians and the Franks became intermixed in the population of the country with the Batavians. (See FRISONS and FRANKS.) Our limits will not allow us to trace the hiſtory of theſe provinces, whilſt they continued ſeparate, and in a great meaſure independent of each other; nor can we detail the various conflicts with which they endeavoured to aſſert and maintain their liberty againſt the tyranny of the king of Spain and his emiſſaries. It will be ſufficient to take up their hiſtory in the year 1566, when Holland and ſome inferior provinces revolted from the oppreſſive dominion of Philip II.; and thus commenced thoſe ſanguinary conteſts, which terminated in the union of Utrecht, Jan. 23d, A.D. 1579. For this purpoſe deputies from the provinces of Holland, Zealand, Utrecht, Frieſland, Groningen, Overyſſel, and Guelderland, met at Utrecht, and ſigned a mutual alliance, which formed the baſis of that commonwealth, which afterwards became ſo renowned under the appellation of the United Provinces. This treaty of alliance was founded upon the infraction of the pacification of Ghent, ſolemnly acceded to by Philip, and a late invaſion of certain towns in Guelderland. It was not intended by this alliance to divide the ſeven provinces from the other 10, or to renounce the pacification of Ghent; but its object was to preſerve the liberty ſtipulated in that pacification, by more vigorous operations, and united councils. The chief articles of this union deſerve to be recited, and they are as follow: the ſeven provinces ſhall unite in intereſt, as one province, never to be ſeparated or divided by teſtament, donation, exchange, ſale, or agreement; reſerving to each particular province and city all its privileges, rights, cuſtoms, and ſtatutes. In all diſputes ariſing between any of the provinces, the reſt ſhall interpoſe as mediators. They ſhall aſſiſt each other with life and fortune againſt every foreign attempt upon any particular province, whether to eſtabliſh ſovereignty, the Catholic religion, arbitrary meaſures, or whatever elſe may appear inconſiſtent with the liberties of the provinces, and the intention of the alliance. All frontier towns belonging to the United Provinces, ſhall, if old, be fortified at the expence of the provinces; if new, at the joint expence of the union. The public impoſts and duties ſhall be farmed for three months to the higheſt bidder, and employed with the king's taxes in the public ſervice. No province, city, or member of the union, ſhall contract an alliance with any foreign prince or power, without the concurrence of all the other members. Foreign powers ſhall be admitted into the alliance, only by conſent of all the contracting parties. As to religion, the provinces of Holland and Zealand ſhall act in that particular as they think adviſeable; the reſt ſhall adhere to the purport of the edict publiſhed by the archduke Matthias, which preſcribed, that no man ſhould be oppreſſed on account of conſcience. All the inhabitants, from the age of 18 to 60, ſhall be trained and diſciplined to war. Peace and war ſhall be declared by the unanimous voice of all the provinces; other matters that concern the internal policy ſhall be regulated by a majority. The ſtates ſhall be held in the uſual conſtitutional manner, and coinage ſhall be deferred to future determination. Finally, the parties agreed, that the interpretation of theſe articles ſhall remain in the ſtates-general; but in caſe of their failing, to decide in the ſtadtholder. In this grand alliance, ſketched out by the prince of Orange, may be diſcerned the judicious ſteady counſel of the maſter and true patriot. It was ſo univerſally approved, that in a ſhort time the cities of Ghent, Nimeguen, Arnheim, Leewarden, Venlo, Ypres, Antwerp, Breda, Bruges, with ſeveral other towns, noblemen and perſons of diſtinction, embraced and ſigned the union. The firſt coin, ſtruck after the alliance is expreſſive of the ſituation of the infant republic. It repreſented a ſhip labouring amidſt the waves, unaſſiſted by ſails or oars, with this motto, "INCERTUM QUO FATA FERANT." The hiſtory of this intereſting ſtruggle, ſays Pinkerton, has been depicted in glaring colours by the celebrated Grotius, who in this work ſometimes rivals the acute brevity of Tacitus. At the end of this century the Dutch had eſtabliſhed colonies at the Cape of Good Hope, and in the Eaſt Indies; and ſettlements were afterwards gained in South America. During the 17th century they rivalled the Engliſh in the empire of the ſea; and greatly exceeded them in commercial advantages. After the obſtinate naval conflicts in the reign of Charles II. their power began to decline. In 1672, Louis XIV. invaded Holland; and Amſterdam was ſaved merely by opening the ſluices. In 1688, William, the ſtadtholder of Holland, aſcended the throne of England; and a ſtricter intercourſe ſubſiſting between the countries, Holland became the grand channel of the commerce of England with the continent. The ſtadtholder was declared hereditary in 1747. By the war in 1756, Holland and France became intimately connected, and a French party aroſe in the country, which oppoſed the ſtadtholder; but he was ſupported by the Engliſh. In 1780, a war occurred between Great Britain and Holland, which terminated in 1784, after expoſing to Europe the decline and weakneſs of the United Provinces, ſtill further diſplayed by the entrance of the duke of Brunſwick in 1788, who may be ſaid to have ſubdued them (ſays Pinkerton) without a blow. As the Dutch joined the coalition againſt the French, their country fell a prey to the invaders, during the hard froſt of the winter of 1794–5; and the ſtadtholder took refuge in England in 1795. The country was then denominated the Batavian republic; and divided into eight departments, &c. However, theſe provinces were ſoon afterwards erected into a kingdom, and aſſigned by Napoleon the French emperor to his brother Louis. On the 1ſt of July 1810, Louis Napoleon abdicated his throne, and it was decreed on the ninth inſtant, by Napoleon, that it ſhould be united to France; that the city of Amſterdam ſhould be the third city of the empire; that Holland ſhould have ſix ſenators, ſix deputies to the council of ſtate, 25 deputies to the legiſlative body, and two judges in the court of caſſation; and that the officers by ſea and land, of whatever rank, ſhould be confirmed in their employments, under commiſſions to be delivered to them, ſigned under the emperor's hand, the royal guard being united to the imperial guard. The emperor's decree announces other proviſional enactments for the management of the adminiſtration, finances, &c. The imperial decree has been ſince executed.

Under their former government, the United Provinces were compoſed of ſeven republics, each retaining its own ſtates, conſiſting of nobles and burgeſſes. The provincial ſtates ſent deputies to the States-general, each republic having only one vote, though its deputies may be numerous. But the States-general ſeldom exceeded twenty-ſix perſons, who uſed to aſſemble in a ſmall room at the Hague, enjoying the right of peace and war, appointing and receiving ambaſſadors, naming the greffier, or ſecretary of ſtate, and all the ſtaff-officers. The council of ſtate directed the army and finances; and what was called the council of deputies conſidered the troops and finances of each province. The grand penſionary of Holland preſided in the provincial ſtates, and council of deputies of that country. The ſtadtholder was, originally, a kind of dictator, appointed, from the neceſſity of the times, to conduct the emancipation of the ſtate. When that neceſſity vaniſhed, the office became of dubious authority, till William III., in 1672, procured it to be declared hereditary. As he died without children, the ſtates revoked this power; but in 1747, it was again made hereditary in favour of William IV.

The new conſtitutional code, under the ſovereignty of Louis, conſiſted of five parts, or rather ſhort chapters. The civil, religious, and political inſtitutions were continued; and the public debt guaranteed. The council of ſtate was compoſed of thirteen members. All forms of religion were tolerated, even that of the king; to whom it pertained to nominate to all offices and places, formerly in the gift of the grand penſionary; for the code takes no notice of the ſtadtholder. The coin was to be ſtamped with his effigy; and, with the advice of the privy council, he had the prerogative of pardoning offences. The government of the colonies was ſpecially and excluſively veſted in him; but the general adminiſtration of the kingdom was committed to four miniſters of ſtate. The legiſlative body was appointed to conſiſt of thirty-eight members, choſen for five years, in a certain proportion for the ſeveral provinces; thoſe for Holland being ſeventeen. The title of high-mightineſſes was retained for the aſſembled members of the legiſlative body, the late grand penſionary being declared preſident for life. This aſſembly was appointed to meet twice in the year, in April and November; but extraordinary aſſemblies might be ſummoned by the king. Juſtice was directed to be adminiſtered according to the local cuſtoms and ſtatutes of each province and city, the ordinances of the States-general, and in defect of all theſe, the Roman code. Each province has a ſupreme court, to which appeals lie from the lower courts of juſtice, except in criminal cauſes, in which the ſtadtholder might pardon, by the conſent of the preſident and ſuperior court of each province, except in caſes of murder and other flagrant crimes.

The army was formerly compriſed at about 36,000, but it has been ſince the revolution incorporated with that of France. The navy, which uſed to conſiſt of forty ſhips of the line, has now almoſt totally diſappeared. The revenue was about 3½ millions ſterling; but the expenditure far exceeded it, ſo that the national debt was computed at about 130,000,000*l.* ſterling; but 2,800,000*l.* were annually received as the intereſt of loans to foreign powers. The dilapidation of the revenue and the increaſe of the debt have been very ſenſible ſince the eſtabliſhment of a nominal monarchy. The political importance of the United Provinces is altogether conſolidated with that of France, of which empire it is become a part, and to which it is abſolutely ſubject. What changes farther await it the wiſeſt politician cannot conjecture. We refer to the article UNITED PROVINCES. Pinkerton's Geogr. vol. i. Mod. Un. Hiſt. vols. xxvii. xxviii.

HOLLAND, a town of Pruſſia, in the province of Oberland, ſituated near the river Weeſke, and ſtrongly fortified; 40 miles S.E. of Dantzic. N. lat. 54° 2'. E. long. 19° 37'.

HOLLAND, *New*, *Notaſia*, or, as Cook called the eaſtern part of it, "*New South Wales*," is an iſland in that part of the globe lately diſtinguiſhed by the name of Auſtralaſia, ſo large as to be entitled to the appellation of a continent. Its length from E. to W. is about 43 degrees of longitude, in the medial latitude of 25°, that is, about 2340 geographical miles, or 2730 Britiſh. The breadth from N. to S. extends from 11° to 39°, being 28°, 1680 geographical, or 1960 Britiſh miles. In the account of Cook's voyage, its ſquare ſurface is ſtated to be more than equal to the whole of Europe. This, however, is an exaggerated eſtimate; becauſe Europe is ſuppoſed to be about 3300 Britiſh miles in its utmoſt length, and its greateſt breadth 2350. This defect is, indeed, compenſated by the proximity of many large iſlands; and the whole of Auſtralaſia will probably be found greatly to exceed the European continent. This immenſe territory was firſt diſcovered in the beginning of the ſeventeenth century, and then called "Terra Auſtralis Incognita." The firſt diſcovery is dated by De Broſſes in October 1616, when the weſtern part was explored by Hartog. In 1628, the weſtern part was diſcovered by ſome veſſels belonging to the Dutch Eaſt India company, and called "De Witt's Land," from the name of the commodore who commanded the ſquadron; and in the following year, a Dutch ſhip, commanded by Capt. Pelſart, was wrecked on this coaſt. In 1642 Capt. Taſman was ſent by the Dutch Eaſt India company to ſurvey the coaſt, who viſited the ſouthern part, which he called "Anthony Van Diemen's Land," by way of contradiſtinction to "Diemen's Land," on the north coaſt. (See DIEMEN's *Land*.) Capt. Dampier fell in with this iſland in 1688, and viſited it again in 1699. He deſcribes the wretched condition of the inhabitants, as deſtitute of houſes and clothes; he repreſents them as black, tall, thin, ſtraight-bodied with ſmall limbs, great heads, heavy brows, and eye-lids half cloſed for guarding their eyes againſt the flies, which were numerous and troubleſome. He further deſcribes them as having large bottle-noſes, full lips and wide mouths, without the two fore-teeth of their upper jaws, and without beards; long-viſaged, and deſtitute of every graceful feature in their faces. The next perſon who viſited this iſland was Capt. Cook, in 1770, who by his extenſive operations on its E. ſide, left little to be done towards completing the full circuit of it. Between Cape Hicks, in latitude 38°, where his examination of this coaſt began, and that part of Van Diemen's Land, whence Taſman took his departure, the diſtance was not above 55 leagues. It was highly probable, therefore, that they were connected; though Capt. Cook cautiouſly ſays, that he could not determine whether his *New South Wales*, (that is, the eaſt coaſt of New Holland,) joins to Van Diemen's Land, or not. But what was thus left undetermined by the operations of his firſt voyage, was, in the courſe of his ſecond, ſoon cleared up. Capt. Furneaux, in the Adventure, during his ſeparation from the Reſolution in 1773, having explored Van Diemen's Land, from its ſouthern point, along the E. coaſt, far beyond Taſman's ſtation, and on to the latitude 38°, where Capt. Cook's examination of it in 1770 had commenced. We have now, therefore, a full knowledge of the whole circumference of this vaſt body of land, though moſt of its interior parts remain ſtill unknown. To the ſouthward of lat. 33° or 34°, the land in general is low and level; far northward it is hilly, but in no part can be called mountainous: and the hills, and mountains, taken together, form but a ſmall part of the ſurface, in compariſon with the vallies and plains. It is rather barren than fertile, though the riſing ground is checquered by woods and lawns, and the plains and vallies are in many places covered with herbage: the ſoil, however, is frequently ſandy, and many of the lawns, or ſavannahs, are rocky and barren, eſpecially towards the northern part, where vegetation is leſs vigorous than towards the ſouth. The inland country appeared to be better clothed than the ſea-coaſt. The banks of the bays are covered with mangroves, to the diſtance of a mile within the beach, under which the ſoil is a rank mud, always overflowed by a ſpring tide; farther within the country, a bog was occaſionally found, upon which the graſs was very thick and luxuriant, and ſometimes a valley occurs, that was clothed with underwood; but the ſoil in general did not ſeem to admit of cultivation. In the interior of the country immenſe ſtrata of coal have been diſcovered. The coaſt, eſpecially to the northward of 25° S. lat. abounds with fine bays and harbours, where veſſels may be ſecure from all winds. The country appeared to be well watered by ſprings and ſmall brooks, but it has no large rivers. Of timber-trees there are but two ſorts; the largeſt is the gum-tree, which grows over the whole country, the gum of which is a deep red, and reſembles the ſanguis draconis, if it be not the ſame; the other grows ſomewhat like our pines. The wood of both is extremely hard and heavy. Others are covered with a ſoft bark, which is the ſame that is uſed in the Eaſt Indies for caulking of ſhips. The country furniſhes three ſorts of palms; the nuts of one of which operated both as an emetic and cathartic with great violence. The quadrupeds of this iſland are the dog, of the chacal kind, which never barks, the kanguroo, an animal of the opoſſum kind, reſembling the phalanger of Buffon, and another like the pole-cat, called by the natives Quoll. Here are many kinds of bats. The ſea and other water-fowl are gulls, ſhaggs, ſoland geeſe or gannets, boobies, noddies, curlews, ducks, pelicans of an enormous ſize, black ſwans, the mænura ſuperba, having its tail expanded in the form of a lyre, and many others. The land birds are crows, parrots, parroquets, cockatoos, and others of the ſame kind, exquiſitely beautiful, pigeons, doves, quails, buſtards, herons, cranes, hawks, and eagles. Among other reptiles, here are various kinds of ſerpents, ſome noxious and ſome harmleſs, ſcorpions, centipeds, and lizards. Of the inſect tribe the principal are the muſquitoe and ant, ſome of the latter of which are green, and form their neſts in a curious manner upon the trees. The ants are of ſeveral kinds. The ſea abounds with fiſh of various ſorts: upon the ſhoals and reef are incredible numbers of the fineſt green turtle in the world, and oyſters of various kinds, particularly the rock oyſter and the pearl oyſter. Here are very large cockles, lobſters, and crabs. In the rivers and ſalt creeks there are alligators.

The number of inhabitants in this country ſeems to be very ſmall in proportion to its extent. The immenſe tract of the interior country remains unexplored, but there is reaſon to believe that it is either wholly deſolate, or more thinly inhabited than the parts viſited by Cook and his companions. The preſumption againſt its being much inhabited is ſtrengthened by the total want of cultivation. The men were of a middle ſize, and in general well made, clean-limbed, and remarkably vigorous, active, and nimble: their countenances were not wholly without expreſſion, and their voices remarkably ſoft and effeminate. The colour of the ſkin could not be well aſcertained, on account of the dirt which uniformly covered it: with the dirt it was as black as that of a negro, and without it ſuppoſed to be of a chocolate colour. In other reſpects the accounts of our navigators materially differ from that of Dampier. They inform us that the features are not diſagreeable, that their noſes are not flat, and that their lips are not thick: their teeth are white and even, and their hair naturally long and black, though univerſally cropped ſhort, and always matted and filthy; their beards are buſhy and thick, but not ſuffered to grow long; both the hair and beard ſeemed to be kept ſhort by ſingeing them. Both ſexes go ſtark naked, without any apparent ſenſe of indecency. Their principal ornament is the bone which they thruſt through the cartilage that ſeparates the noſtrils: it is as thick as a man's finger, and being five or ſix inches long, reaches quite acroſs the face, and is an impediment both to their breathing and ſpeaking. They had alſo necklaces made of ſhells, neatly cut and ſtrung together: bracelets of ſmall cord, twiſted two or three times round the arm, and a ſtring of plaited human hairs round the waiſt. They paint their bodies both white and red, the latter forming broad patches upon the ſhoulders and breaſt, and the former being drawn in ſtripes over various parts of their bodies. Theſe people had no idea of traffic: they received what was given them, but had no idea of making a return, nor did they ſeem to have any diſpoſition to ſteal: but if they were refuſed what they aſked for, *e. g.* a turtle, they were enraged, and endeavoured to take it by force. On their bodies were viſible ſcars, inflicted by blunt inſtruments, and which were underſtood to be memorials of grief for the dead. They appeared to have no fixed habitations, nor was there any trace of a town or village in the country. Their houſes, when they had any, were mere hovels, conſtructed with pliable rods and covered with leaves of palm or broad pieces of bark: but in general they ſlept without any ſhelter, except the buſhes, or graſs, which is here near two feet high. Their fiſh-hooks are neatly made; and their lines, made of ſome vegetable ſubſtance, are from the thickneſs of a half-inch rope to the fineneſs of a hair. Their chief food is fiſh, and they occaſionally kill a kanguroo and ſome birds: the only vegetable that forms an article of food is the yam. They dreſs their animal food by boiling, broiling, or baking it. As they have no nets, they catch fiſh only by ſticking with an inſtrument of wood adapted to the purpoſe, or with a hook and line. They produce fire with facility, and ſpread it in a wonderful manner. To produce it they take two pieces of dry ſoft wood, one being a ſtick about eight or nine inches long, and the other a flat piece: the former is ſhaped into an obtuſe point at one end, and preſſing it upon the other, they turn it nimbly by holding it between both their hands, as we do a chocolate mill, often ſhifting their hands up and down, to increaſe the preſſure. By this method they get fire in leſs than two minutes; and then ſpread it by means of the dry graſs. The weapons of this people are ſpears, or lances, of different kinds, pointed with bone or ſhells, and barbed; and they throw them with great force and dexterity, either by the hand for ſhort diſtances, or with an inſtrument contrived for that purpoſe: they have alſo ſhields or targets made of the bark of a tree. Their canoes are as rudely conſtructed as their houſes, of bark or the trunk of a tree hollowed, probably by fire. They are moved with a pole or paddles, and ſome of them are fitted with an outrigger to prevent their overſetting: they are of different lengths and very narrow. The only tools which they ſeemed to poſſeſs was an adze made of ſtone, wedges of the ſame material, a wooden mallet, and ſome ſhells, and fragments of coral. For poliſhing the points of their lances, &c. they uſe the leaves of a kind of wild fig-tree. Each of their canoes carries four people.

The eaſtern coaſt of New Holland was carefully examined by Capt. Cook, and formally taken poſſeſſion of in the name of the king of Great Britain in 1770. At the cloſe of the American war, it was determined by the Britiſh government to make a ſettlement on this coaſt for the accommodation of tranſported felons. (See Botany-*bay*.) It appears from ſome further diſcoveries and reports, pertaining to this country, that it is peopled by three or four diſtinct races of men; thoſe in the S.W. being different from thoſe in the N., and both from thoſe in the E. above deſcribed. They are merely divided into families, the former being ſtyled Be-ana, or father, which is a title of reſpect; and each family or tribe has a diſtinct place of reſidence, diſtinguiſhed by adding "gal" to the name of the place; *e. g.*, the ſouthern ſhore of Botany-bay being called "Gwea;" the tribe inhabiting it is denominated "Gwea-gal." Thoſe who live on the north ſhores of Port Jackſon are called "Cam-mer-ny-gal," Cammer-rhy being the name of that part of the harbour. This tribe, which is numerous and muſcular, exerciſe the prerogative of exacting a tooth from young men of other families, in token of government or ſubordination. This tribute of teeth is paid in a ſolemn manner, and it is performed every four years. They manifeſt but very obſcure traces of religion, though they have ſome faint ideas of a future exiſtence in the clouds, whence they originally fell. They ſeem raiſed but one degree above the brute creation; and, like monkies, they are great mimics. The deformity of their appearance, occaſioned by their low ſtature and thin limbs, their black buſhy beards, and the bone ſtuck in the cartilage of the noſe, by an operation performed between the ages of eight and ſixteen, is farther increaſed by their practice of rubbing fiſh oil into their ſkins as a protection from the air and muſquitoes, and of colouring their faces with white or red clay. The women are marked by the loſs of the two firſt joints of the little finger of the left hand, which, as well as the extraction of a tooth from the boys, is ſuppoſed to inure them to bear pain with apathy. It is ſaid, however, that theſe joints of the little finger are parted with becauſe they are in the way when they wind their fiſhing lines over the hands. Few inſtances of deformed perſons occur. Their huts are commonly conſtructed of the bark of trees, in the form of an oven, having the fire at the entrance, and filled with ſmoke and naſtineſs, in which they ſleep promiſcuouſly. Their mode of courtſhip is not very gallant; as it conſiſts in watching the lady's retirement, and then knocking her down with repeated blows of a club, or a wooden ſword; after which the matrimonial victim is led, ſtreaming with blood, to her future huſband's party, when a ſcene enſues too ſhocking to relate. The men of one tribe ſeek wives among the women of another. The woman thus raviſhed is called a wife; and polygamy is common. Parturition is eaſy, and a few hours after the mother walks about her uſual buſineſs. The infant is placed for a few days on a piece of ſoft bark; but is ſoon removed to the mother's ſhoulders with its legs acroſs her neck, ſecuring itſelf by catching hold of her hair. Superſtition is very prevalent among theſe poor ſavages; they believe in magic, witchcraft, and ghoſts, the latter being the night-mare. They have alſo ſpells againſt thunder and lightning, and pretend to foretel future events by the meteors called falling ſtars. They are ſubject to a diſeaſe reſembling a violent itch; but for their venereal complaints they ſeem to have been indebted to Europeans. They have not only perſonal property in their weapons, and fiſhing tackle, but ſome are ſuppoſed hereditary properties of certain ſpots, perhaps aſſigned as rewards for public ſervices, or acts of great bravery. They are repreſented, with regard to their habitual diſpoſition, as revengeful, jealous, courageous, and cunning. If they were honeſt, when firſt viſited by Europeans, they have ſince acquired the art of ſtealing; and they are ſaid to be adepts in the arts of evaſion and lying. Savage, as their ſtate is, they are ſuſceptible of friendſhip, and capable of feeling ſorrow. They have names for the ſun and moon, ſome few ſtars, the magellanic clouds, and the milky way. Young people are buried; but thoſe who have paſſed the middle age are burnt; a rude tumulus being erected as a tomb. Mr. Collins, in his account of this iſland, has given an ample vocabulary of the language; which is ſaid to be grateful to the ear, expreſſive, and ſonorous, and to have no analogy with any other known language; but the dialects of the various regions ſeem to be entirely different. The ſeaſons are like thoſe of the ſouthern part of Africa and America; and as the country lies on the ſouthern ſide of the equator, they are the reverſe of thoſe in Europe. The climate, however, is allowed to be very fine and ſalubrious. The rains are heavy, falling chiefly about the full and change of the moon, and at intervals there are ſtorms of thunder and lightning. Of the lakes, rivers, and mountains of this extenſive country, our information is hitherto very imperfect; but they may probably be found to be on a large ſcale. A chain of mountains is ſaid to run N. and S. between 50 and 60 miles inland, but not eaſily acceſſible, on account of numerous deep ravines. Baſaltic columns often appear; and in Howe's iſland they are ſaid to riſe ſo high, as to be viſible at the diſtance of twelve leagues.

The whole of the S.W. coaſt of New Holland has been explored by D'Entrecaſteaux; who has made correct charts of it, and other parts have alſo been inveſtigated, ſo that in due time we ſhall have a more complete account of this extenſive iſland, or group of iſlands, if, indeed, it conſiſt, as ſome have ſuggeſted, of ſeveral. S. lat. about 11° to 39°. E. long. 113° to 156°.

Holland, a townſhip of America, in Hampſhire county, Maſſachuſetts, bounded S. by Holland county in Connecticut, E. by Worceſter county, and northward by Brimfield, incorporated in 1785, and containing 445 inhabitants; 75 miles S.W. by W. of Boſton.

Holland, *Cape*, a cape in the ſtraits of Magellan. S. lat. 53° 57'. W. long. 72° 34'.

Holland's *Iſlands*, iſlands of America, near to the S. of Hooper's iſland, in Cheſapeak bay.

Holland's *Point*, a cape on the W. ſide of Cheſapeak bay, which, together with Parker's iſland, forms the mouth of Herring bay.

Holland *River*, a river of Upper Canada, running from the S.W., and diſcharging itſelf into Cook's bay, lake Simcoe.

HOLLANDEROCELLER Irsceat, a ſmall iſland in the North ſea, near the W. coaſt of Eaſt Greenland. N. lat. 60° 38'. W. long. 46° 25'.

HOLLATT, a town of Auſtria, on the Danube; ſix miles N.N.W. of Bruck.

HOLLEMOPPO, a town on the N. W. coaſt of the iſland of Timor. S. lat. 9°. E. long. 124° 50'.

HOLLENBACH, a town of Germany, in the principality of Hohenloe; 17 miles N.E. of Ohringen.

HOLLERIUS, James, or, in his native language, Houllier, in *Biography*, a French phyſician and ſurgeon, of ſome eminence in the ſixteenth century, was born at Eſtampes, and took his doctor's degree in the faculty of Paris, of which he was elected dean in 1546. He obtained great reputation by the ſucceſs of his practice both in medicine and ſurgery, and is ſaid to have paid particular attention to render the mind cheerful under illneſs, with a view to facilitate the cure of corporeal diſeaſes. He was the author of ſeveral works, none of which he publiſhed himſelf. Some were printed during his life under the ſuperintendance of his pupils, and ſome after his death, which happened in 1562. Among his works were commentaries on the books of Galen "De Compoſitione Medicamentorum," and on the Aphoriſms of Hippocrates; likewiſe a treatiſe "De Materia Chirurgica," in three books, which went through numerous editions, in ſome of which the title of "Inſtitutiones Chirurgicæ" was adopted; "De Morborum curatione, &c." 1565; and "De Morbis internis Libri duo," 1571, which was frequently reprinted. Eloy. Dict. Hiſt.

HOLLES, Denzil, *lord*, ſecond ſon of the firſt Holles, earl of Clare, was born in 1597. He was liberally educated,

cated, and when his father had a place at court he was for a time companion and bed-fellow to prince Charles, then duke of York. When he attained to a proper age he ſat in parliament as member for St. Michael's, Cornwall, and ſided with the oppoſition party. At the acceſſion of Charles I. he refuſed the offer of a knighthood of the Bath, and in the parliament of 1627 he was, owing to the intereſt which he had acquired by his marriage, returned for Dorcheſter, and took a leading part in favour of liberty. When the three reſolutions of the commons againſt Popery, Arminianiſm, and the levying of tonnage and poundage by the king's prerogative, were drawn up, he was one of the two who forcibly held the ſpeaker in his chair till they were paſſed. For his conduct on this occaſion he was proſecuted, and condemned to a fine and impriſonment in the Tower, where he remained twelve months. Irritated by this treatment, and fixed in his principles, he entered the long parliament in 1640, a determined foe to the court, and by the vigour and abilities which he manifeſted, he was placed at the head of the Preſbyterian party. His relationſhip with the earl of Strafford preventing him from taking a part againſt that nobleman, he carried up the impeachment of archbiſhop Laud. He was one of five members accuſed by the king of high treaſon in 1641, and the attempt at ſeizing them was the immediate cauſe of taking up arms. In the enſuing war the parliament gave him the command of a regiment, and appointed him lieutenant of Briſtol. Mr. Holles, however, ſoon ſaw through the deſigns of the independent party, and with the view of fruſtrating them he endeavoured to promote a treaty with the king. At length he was obliged to eſcape to France to avoid a proſecution for high treaſon from the party with whom he had acted. By the interpoſition of his friends he was allowed to return in 1648, when he reſumed his ſeat in parliament, and was one of the perſons appointed to treat with the king in the Iſle of Wight. He was not prepared to go to all the lengths of his party, and was again obliged to quit the country to enſure the ſafety of his perſon. He took up his abode in Britanny, where he continued till the year preceding the reſtoration, which event he had uſed all his influence to promote. On the reſtoration he was advanced to the peerage by the ſtyle of lord Holles of Iſfield, in the county of Suſſex. He was now employed by the court in various negociations, but his attachment to the principles of liberty remained unabated, and when the politics of the reign tended to render the king abſolute, he appeared as a leader in oppoſition. No man had a more diſintereſted love of his country than lord Holles, a proof of which was exhibited, when offered by parliament 5000*l.* as a reparation for the loſſes which he had ſuſtained in the civil war: "I will not," ſays he, "receive a penny till the public debts are paid." He died in 1679, in the 82d year of his age. He was buried in Dorcheſter church, where a monument was raiſed by his great nephew John duke of Newcaſtle. Biog. Brit. Hume.

HOLLES, in *Geography*, the *Niſitiſſet* of the Indians, a townſhip of America, in Hillſborough county, New Hampſhire, on the Maſſachuſett's line, incorporated in 1746; about 70 miles S.W. of Portſmouth, and containing 1557 inhabitants.

HOLLFELD, a town of Bavaria, in the biſhopric of Bamberg, in the Wiſent; 15 miles E. of Bamberg.

HOLLI, the Indian name for what the Spaniards call *ulli*; a reſinous liquor, which flows ſpontaneouſly from the tree *holquaghuytl*, or *chilli*. It is often mixed with chocolate in the making, in the proportion of one fourth part; it gives the chocolate in this caſe no very diſagreeable flavour; and becomes a very powerful medicine in dyſenteries. It is uſual, however, before the making it, to mix the cacao and holli on an iron plate, and torrify them thoroughly together.

HOLLIS, THOMAS, in *Biography*, was born at London in April, 1720. Being deſigned for commercial life, he was ſent, when about 14 years of age, to Amſterdam, for the purpoſe of learning the French and Dutch languages, and merchants' accounts. Soon after his return, in 1735, his father died, and as he was now heir to a large eſtate, it was reſolved to complete his education on a liberal plan. With this view he was placed under the care of Dr. Ward, profeſſor of rhetoric in Greſham college, with whom he ſtudied the learned languages, and other branches of literature. In 1740 he took chambers in Lincoln's Inn as a law ſtudent, and probably with ſome view of following the profeſſion, but though he lived there eight years, it does not appear that he applied himſelf, profeſſedly, to the ſtudy of the law. He did not, however, waſte his time in idle amuſements and diſſipation; he had already formed an acquaintance with perſons eminent for their attachment to liberty; and had imbibed their principles, which ſtrongly marked his character through life. Even when a boy at ſchool, he was intereſted in the noble deeds of the heroes of antiquity, "I uſed," ſaid he, "to rob nature of her reſt to read Plutarch, honeſt Plutarch, and read again the lives of his heroes. To him, I owe, I willingly confeſs, the fineſt diſpoſitions of my mind." In 1748 he ſet out on a tour upon the continent, and the journal which he kept while he was abſent proves that he ſuffered nothing worthy of obſervation to eſcape his notice. In 1750 he made a ſecond tour, and finding on his return that he could not gratify his wiſh of ſerving his country, by entering into parliament, without compliances which were contrary to his principles, he began to make a collection of books and medals for the purpoſe of preſerving the memory of the champions of liberty; and, in general, for the ſervice of ſcience and art. It was alſo one of his leading objects to print, and preſent to his friends, books favourable to the popular principles of government. Milton and Algernon Sidney were the authors that attracted his principal admiration. He inveſtigated with great minuteneſs the hiſtory of Milton and his works, and cauſed engravings to be made of his portrait taken at different periods. The particulars of Mr. Hollis's life are little more than a liſt of generous and public ſpirited actions, either for the relief and encouragement of individuals, or for the promotion of what he conſidered the moſt important intereſts of mankind. There were few uſeful and benevolent inſtitutions of which he was not a member, and a liberal patron. The books which he publiſhed, or procured to be publiſhed, were "Wallis's Grammar of the Engliſh Language;" "Locke on Toleration and Government;" "Sydney on Government;" "Needham's Excellency of a free State;" "Neville's Plato Redivivus;" and "Staveley's Romiſh Horſeleach." He likewiſe cauſed ſeveral pamphlets from America to be reprinted at his own expence. He encouraged the printing of other works favourable to liberty, by taking large numbers of copies and diſtributing them as preſents. His munificence in this reſpect contributed very much to extend the knowledge of Engliſh literature and Engliſh generoſity through foreign countries. In 1770 he retired into the country, where he employed himſelf in improving his eſtate at Corſcombe in Dorſetſhire. He kept many workmen conſtantly employed in his ſervice, to ſome of whom he was giving directions on New Year's day 1774, when he dropt down in a fit and immediately expired. Mr. Hollis, ſays one of his biographers, was of an athletic make, inclined to corpulence, which he counteracted by great abſtemiouſneſs of diet, and ſtrong exerciſe. He allowed himſelf ſcarcely any of the indulgencies of a man of fortune, and oppoſed the growing luxury of the age, as well by his example as by his precepts. His particular ſentiments with regard to religion were known to himſelf only. He joined no ſect, and attended no place of worſhip, but his diary contains a multitude of proofs of his veneration and gratitude to the Supreme Being. He was, in every reſpect, an univerſal philanthropiſt, and it was ſaid of him, "that in his death Liberty loſt her champion, Humanity her treaſurer, and Charity her ſteward." Hollis Memoirs, 2 vols. 4to. 1780.

HOLLISTON, in *Geography*, a townſhip of America, the moſt ſoutherly in Middleſex county, Maſſachuſetts; 28 miles S. by W. of Boſton; incorporated in 1724, and named in honour of Thomas Hollis, eſq., of London, and now containing 783 inhabitants.

HOLLMAN, Samuel Christian, in *Biography*, was born at Stettin in 1696, where he received the elementary principles of a learned education. His maturer ſtudies he purſued at Wittenburg, took his degree of M. A. in 1720, and for a ſhort time he read lectures at Greifswald and Jena. In 1734 he was invited to be public profeſſor of philoſophy in the univerſity of Gottingen, then lately founded, and upon the eſtabliſhment of the ſociety of the ſciences he was the firſt regular member of the philoſophical claſs. Here he continued his lectures till the year 1784, when he reſigned the duties of his office. He died in 1787. The univerſity of Gottingen was under vaſt obligations to this learned man, who with Haller contributed to diffuſe through Germany a taſte for natural philoſophy and natural hiſtory. On theſe ſubjects he publiſhed ſeveral excellent papers in the tranſactions of the royal ſocieties of Gottingen and London. He likewiſe diſtinguiſhed himſelf by various elementary works and diſſertations, which are enumerated in the General Biography, to which the reader is referred.

HOLLOA, in *Sea Language*, is an exclamation of anſwer to any perſon who calls to another to aſk ſome queſtion, or to give a particular order. It is alſo the firſt anſwer in hailing a ſhip at a diſtance.

HOLLOLA, in *Geography*, a town of Sweden, in the province of Tavaſtland; 30 miles E. of Tavaſthus.

HOLLOW, in *Architecture*, a concave moulding, about a quadrant of a circle, by ſome called a *caſement*, by others an *abacus*.

Hollow-*quoins*, in *Engineery*, are piers of ſtone or large bricks made on purpoſe behind each lock-gate of a canal, which are formed into a hollow from top to bottom to receive the rounded head of the lock-gates: in ſome inſtances the hollow-quoin is formed of one piece of oak cut to the proper ſhape and fixed vertically againſt the wall, and even caſt iron has been uſed, on ſome recent occaſions, for forming the hollow-quoin or hinge for the lock-gates of large canals, or the entrance baſons to docks. See our article Canal.

Hollow *Roots*, in *Botany* and *Gardening*. See Fumaria.

Hollow *Square*, in *Military Language*, is a body of foot, drawn up with an empty ſpace in the middle, for the colours, drums, and baggage; facing and covered by the pikes every way, to oppoſe the horſe.

Hollow *Tower*, in *Fortification*, is a rounding made of the remainder of two briſures, to join the curtin to the orillon, where the ſmall ſhot are played, that they may not be ſo much expoſed to the view of the enemy.

Hollow-*toothed Horſe*, in the *Manege*. See Shell-*toothed*.

Hollows, in *Mining*, denote the waſtes, gobbins, or old hollows in coal-pits, from whence the coals have been wrought or gotten. The old hollows in many coal works generate *Damps* (ſee that article), or foul air, which is very prejudicial to the works; and, in ſome inſtances, the waſte coals in them are fired by the pyrites, duns, and other ſelf-inflaming ſubſtances among them, if the air be not excluded from theſe hollows; as at Doniſthorpe colliery, in Derbyſhire, and others near Dudley, in Staffordſhire. See Farey's Derbyſhire Report, vol. i.

HOLLOWNESS *of* Trees. This is one of the moſt miſchievous diſtemperatures to which trees are ſubject. It is generally occaſioned by the lopping of them in an improper manner, and leaving the wet to fall in upon them, eſpecially on their heads. When this miſchief is found out in its beginning, the only method is to cut the trunk off to the quick, ſacrificing the whole hollow part; it is, in this caſe, to be cut off ſloping, that the wet may run off from it. All ſoft woods are liable to this miſchief, after the lopping, particularly the elm; and when it takes hold of any tree, it grows upon it daily, till the whole ſubſtance of the tree is at length eaten away, and only a coat of bark is left. The beſt way of preventing it in the elm, is never to cut off the head or top of the tree at all, but only to lop the ſide branches: theſe will yield a very large quantity, and the body of the tree will thrive the better for their being often cut off, and will be good timber at laſt. Theſe tall elms ſometimes grow hollow from another cauſe, that is, from the decay of ſome of the large roots; but the ſtarving condition of its branches will ſhew this, though there be no external mark of it. This ſort of hollowneſs always begins at the bottom of the tree. Blaſted parts of the trees are to be cut away to the quick, in the ſame manner as the hollow ones, and the wounds will heal in the ſame manner.

HOLLS, in *Geography*, a lake of Norway, in the dioceſe of Aggerhuus; 70 miles N. of Chriſtiania.

HOLLY, in *Botany* and *Gardening*. See Ilex.

The common holly is often found uſeful as a hedge plant. It is a plant which on good, dry, loamy ſoils, grows to a conſiderable ſize; but which on poor wet ſoils ſeldom becomes more than a low ſhrub. It has been recommended as making an impenetrable fence, and as bearing to be cropped with but little injury; and that ſheep are capable of being fed in the winter with the croppings; while birds conſume the berries. The bark, when fermented, and then waſhed from the woody fibres, conſtitutes the common bird-lime. And the beauty of its ſcarlet berries are aſſerted never to ſuffer from the ſevereſt of our winters. The wood is found excellent for veneering; being occaſionally ſtained black in imitation of ebony. (See Marquetry.) It is uſeful for the handles of knives, as well as the coggs of mill-wheels. Provincially it is not unfrequently denominated *Hollin*.

A late writer contends, that "no plant makes ſo good a hedge as holly; if preſerved with any attention in its infancy it will, in a few years, be impenetrable to man or beaſt. It often fails from being planted at an improper ſeaſon; for there is not the leaſt certainty of any ſucceſs, except by planting about Midſummer. The plants ſhould be from ſix to nine inches high, and well rooted: they ſhould not be let into the ſloping face of a bank, but on a level tablet left for that purpoſe, and well defended on both ſides, to keep both ſheep and hogs from it." This is one of thoſe plants that may likewiſe be intermixed with the white thorn in the conſtituting of hedge fences, and which by its mixture renders them ſtill more beautiful. See Fence and Hedge.

Holly, *Knee*, in *Botany* and *Gardening*, and the *Materia Medica*. See Ruscus.

Holly, *Sea*, the name by which ſome call the *eryngium* of botanical writers. See Eryngo.

Holly-*wood*, *Petrified*, in *Natural Hiſtory*. In the accounts which are given in the Philoſophical Tranſactions, N° 158, of the ſuppoſed petrifying qualities of the waters of Lough Neagh in Ireland, ſome of the pieces of petrified wood found in its banks are denominated *holly*; but apparently for no better reaſon, than becauſe they were white: correct obſervations have never, we believe, detected holly or any other recent ſpecies of wood in the ſtrata: the leaves and twigs of holly obſerved by Dr. Correa de Serra, on the coaſt of Lincolnſhire, evidently belong to the recent or peat foſſils, and not to thoſe of the ſtrata.

HOLLY-HOCK, in *Botany* and *Gardening*. See Alcea.

HOLLYMOUNT, in *Geography*, a ſmall poſt-town of the county of Mayo, province of Connaught, Ireland, ſituated on the river Robe. It is on the road from Dublin to Caſtlebar through Tuam, and is 107 miles W. by N. from Dublin, and 14 from Caſtlebar.

HOLM, Hulmus, ſignifies as much as *inſula amnica*, a river iſland, according to Bede; or a plain, graſſy ground, upon the water-ſide, or in the water, according to Camden.

Where any place is called by the name holm, or where this ſyllable is joined with any other in the name of a place, it ſignifies it to be ſurrounded with waters. As the *flatholmes*, the *ſtepholmes*, near Briſtol. If the ſituation of the place be not near the water, it may ſignify a hilly place; for holm, in Saxon, alſo ſignifies a *hill*, or *cliff*.

Holm, or *Holme*, in *Agriculture*, the common name of a low, flat, rich tract of land, which uſually lies on the border of a large river. This ſort of land is fit for almoſt any ſort of culture, but particularly ſo for thoſe of paſture, feeding, and hay. See Holm *Land*.

Holm *Land*, that deſcription of rich ground which is met with on the ſides of large ſtreams of water. This is obviouſly a water-formed kind of land, being gradually conſtituted by time from the frequent depoſitions of the rivers or ſtreams during the periods of their being covered by the floods proceeding from them. This is very clear from the circumſtance of ſuch ſorts of land being uniformly found on the banks of ſuch ſtreams as have a flow, ſmooth courſe, and which are liable to be overflowed by them. Where ſuch ſtreams are uſually diſcharged into larger and more expanded ſpaces of water, it is common to find the more valuable kinds of this ſort of land. In ſome particular caſes of this deſcription of land, it is not unuſual to find the ſoil approaching, in ſome meaſure, to that of a clayey quality; but which, when properly freed from water, and ſubjected to good cultivation, ſpeedily becomes excellent land. Indeed all theſe ſorts of lands are in general well ſuited either for the growth of graſs or grain, moſtly producing heavy crops of the latter as well as the former; but from their being in moſt inſtances ſubject to be overflowed, they are probably more proper for being kept under the graſs ſyſtem.

Holm *Oak*. See Quercus.

Holm, in *Geography*, one of the ſmaller Orkney iſlands, one mile E. of Weſtra.—Alſo, a ſmall iſland between Pomona and Hoy.—Alſo, a ſmall iſland, two miles W. of Eda.—Alſo, a ſmall iſland, on the coaſt of Eſſex, in a large bay. N. lat. 51° 53′. E. long. 1° 10′.—Alſo, a town of Sweden, in the province of Angermannland; 40 miles N.N.W. of Hernoſand.

Holm *Kirk*, a town of the iſland of Pomona; nine miles S.E. of Kirkwall.

HOLME. See Holm.

HOLMES, *Flat and Steep*, in *Geography*, two ſmall iſlands ſituated in the Britiſh channel, between Glamorganſhire and Somerſetſhire. The former contains about 60 acres of land, and is diſtinguiſhed for its light-houſe. Several pilots reſide on it. The Steep Holmes is a ſmall rocky iſland, the higheſt point of which riſes 400 feet above the level of the ſea. It is almoſt diveſted of vegetation, but is the reſort of large flocks of ſea fowls during the ſummer ſeaſon. This ſolitary and inhoſpitable ſpot is ſaid to have been a place of refuge to the ancient Britiſh hiſtorian, Gildas, who hoped thus to preſerve his life from the marauding Picts and Scots. He afterwards retired to Glaſtonbury.

Holmes's *Hole*, a commodious and ſafe American harbour, in Duke's county, Maſſachuſetts, on the N. ſide of Martha's Vineyard; 98 miles S.E. of Boſton.

HOLMESTRAND, a town of Norway, in the province of Aggerhuus; 30 miles S. of Chriſtiania. N. lat. 59° 30′. E. long. 10° 30′.

HOLMON, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 63° 48′. E. long 20° 37′.

HOLMSKIOLDIA, in *Botany*, was named by profeſſor Retzius of Lund, in honour of a Daniſh nobleman, Theodore Holm, afterwards Holmſkiöld, who wrote a treatiſe in Daniſh on *Anagallis*, in 1761, and a ſplendid folio in Latin and Daniſh on Fungi, explaining the ſtructure of the *Clavariæ* and ſome of their allies, publiſhed at Copenhagen in 1790. He was born in 1732 and died in 1794, according to Dryander's Bibl. Banks, v. 5. 287.—Retz. Obſ. faſc. 6. 31. Willd. Sp. Pl. v. 3. 360. (Haſtingia; Sm. Exot. Bot. v. 2. 41. Intr. to Bot. 403. See Hastingia.)—Claſs and order, *Didynamia Gymnoſpermia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very large, coloured, turbinate, gradually expanding into a wide bell-ſhaped limb, with five ſhallow, equal, unarmed lobes. *Cor.* of one petal, ringent, tubular; tube longer than the calyx, ſwelling upwards; upper lip ſhorteſt, aſcending, cloven, obtuſe; lower in three rounded lobes, the middle one largeſt, entire. *Stam.* Filaments four, thread-ſhaped, rather longer than the upper lip, two of them ſhorter than the reſt; anthers incumbent, roundiſh, ſimple. *Piſt.* Germen ſuperior, four-cleft; ſtyle the ſize of the ſtamens and ſituated between them, its ſummit bent downward; ſtigma in two ſharp lobes. *Peric.* none, except the faded, ſcarioſe, permanent calyx. *Seeds* four, naked, in the bottom of the calyx, ſomewhat obovate, rugged.

Eſſ. Ch. Calyx bell-ſhaped, dilated, much wider than the corolla, coloured, in five ſhallow, equal, unarmed lobes.

1. H. *ſanguinea*. Retz. and Willd. as above. (Haſtingia coccinea; Sm. Exot. Bot. v. 2. 41. t. 80.)—Gathered by Koenig and by lieutenant-colonel Thomas Hardwicke, in vallies among the mountains of the north part of Bengal, flowering in February or March, and ripening ſeed in April. It is called by the people of the country *Ghurhulpaharia*, a name almoſt as difficult of pronunciation as *Holmſkioldia*, which we are told is ſpoken as if it were written *Holmſhouldia*, to the no ſmall comfort of thoſe who, like us, are forced to adopt it, in juſtice to its meritorious prototype, and thoſe who have delighted to honour him. The original appellation of this new and curious genus, given by Koenig, *Haſtingia*, was retained in the Exotic Botany, becauſe the writer of that work could have no ſuſpicion of any one's having committed ſo great an error as to place this plant in the order

Angioſpermia, its characters and affinity being ſo manifeſtly near *Phlomis* and *Moluccella* in the *Gymnoſpermia*. It was, therefore, concluded to be unpubliſhed.

The only known ſpecies of this genus is a very handſome ſhrub, whoſe *ſtem* is ſmooth, roundiſh, with many oppoſite branches. *Leaves* oppoſite, on furrowed ſtalks, without ſtipulas, ovate, pointed, veiny, two or three inches long, ſlightly ſerrated, almoſt perfectly ſmooth, dotted on both ſides, paler beneath. *Flowers* in terminal, looſe, bracteated bunches, of a vivid ſcarlet. *Flower-ſtalks* downy. *Calyx* an inch wide, veiny, ſlightly downy, as richly coloured as the *corolla*, which is alſo pubeſcent, longer than the calyx, but much narrower, as in *Moluccella*. *Seeds* black.—This plant would be a great ornament to our ſtoves, and might probably ſucceed in a conſervatory with leſs heat than tropical vegetables generally require.

What the worthy Retzius ſaw when he examined "a half-ripe capſule" of this ſhrub, in which he "manifeſtly obſerved ſeveral ſeeds, but could not abſolutely judge whether it were unicapſular (meaning unilocular) or not," we are utterly unable to imagine.

HOLO, in *Geography*, a town of Sweden, in Sudermanland; 24 miles S.W. of Stockholm.

HOLOCAUST, Ὁλοκαυςον, formed from ὅλος, *whole*, and καιω, *I conſume with fire*, a kind of ſacrifice, wherein the whole offering is burnt or conſumed by fire; as an acknowledgment that God, the Creator, Preſerver, and Lord of all, was worthy of all honour and worſhip, and as a token of men's giving themſelves entirely up to him. It is called alſo, in ſcripture, a *burnt-offering*.

Sacrifices of this ſort are often mentioned by the Heathens as well as Jews; particularly by Xenophon, Cyropæd. lib. viii. p. 464. ed. Hutchinſ. 1738, who ſpeaks of ſacrificing holocauſts of oxen to Jupiter, and of horſes to the ſun; and they appear to have been in uſe long before the inſtitution of the other Jewiſh ſacrifices by the law of Moſes. Accordingly, we find this kind of ſacrifice was offered by Noah and Abraham, and alſo by Job, and Jethro, the father-in-law of Moſes. See Job, i. 5. chap. xlii. 8. Gen. xxii. 13. chap. viii. 20. On this account, the Jews, who would not allow the Gentiles to offer on their altar any other ſacrifices peculiarly enjoined by the law of Moſes, admitted them by the Jewiſh prieſts to offer holocauſts; becauſe theſe were a ſort of ſacrifices prior to the law, and common to all nations. During their ſubjection to the Romans, it was no uncommon thing for thoſe Gentiles to offer ſacrifices to the God of Iſrael at Jeruſalem. Vide Philo. Opera. p. 801. E. Ed. Colon. Allobr. 1613. Tertullian. Apolog. § 26. p. 26. ed. Rigalt. 1675.

Holocauſts were deemed by the Jews the moſt excellent of all their ſacrifices. It is ſaid, that this kind of ſacrifice was in common uſe among the heathens, till Prometheus introduced the cuſtom of burning only a part, and reſerving the remainder for his own uſe.

HOLOGNE-AUX-PIERRES, in *Geography*, a town of France, in the department of the Ourte, and chief place of a canton, in the diſtrict of Liege. The place contains 678, and the canton 17,815 inhabitants, on a territory of 147½ kiliometres, and 30 communes.

HOLOGRAPHUM, compoſed of ὅλος, *all*, and γραφω, *I write*, in the *Civil Law*, ſomething written wholly in the hand-writing of the perſon who ſigns it.

The word is chiefly uſed in ſpeaking of a teſtament, written wholly in the teſtator's own hand. See TESTAMENT.

The Romans did not approve of holographic teſtaments; and, though Valentinian authorized them by a novel, they are not uſed where the civil law is in full force.

HOLOKLUB, in *Geography*, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 60° 51'. E. long. 17° 7'.

HOLOMETER, compoſed of ὅλος, *all*, and μετρεω, *I meaſure*, a mathematical inſtrument ſerving univerſally for the taking of all ſorts of meaſures, both on the earth and in the heavens.

The holometer is the ſame with what is otherwiſe denominated *pantometer*; which ſee.

HOLOMIN, in *Geography*, a ſmall iſland of Scotland, near the W. coaſt of the iſland of Mull.

HOLOSERICA VESTIS, a garment entirely of ſilk, as the name imports, which was not uſed at Rome till the time of Heliogabalus.

HOLOSIE, in *Geography*, a town of Auſtrian Poland, in Gallicia; 40 miles W.N.W. of Lemberg.

HOLOSTEMMA, in *Botany*, from ὅλος, *entire*, and ςεμμα, *a crown*, becauſe the crown of the ſtamens is a ſimply annular undivided body. Brown Aſclep. (from Tr. of the Wernerian Society, v. 1.) p. 31.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juſſ. *Aſclepiadeæ*, Brown.

Eſſ. Ch. Corolla ſomewhat wheel-ſhaped, five-cleft. Crown of the ſtamens inſerted at the bottom of their tube, ſimple, annular, entire. Anthers terminated by a membrane; maſſes of pollen pendulous, compreſſed, attached by their ſlender ſummits. Stigma pointleſs. Follicles ſwelling, ſmooth. Seeds with a hairy crown.

The only ſpecies indicated by the author is the *Adakodien*, Rheede Hort. Malab. v. 9. 9. t. 7, found in the Eaſt Indies. This is a twining ſmooth *ſhrub*. The *leaves* are oppoſite (erroneouſly drawn alternate in the figure), ſtalked, croſſing each other in pairs, heart-ſhaped, three or four inches long, entire, ſoft, ſmooth, milky, but not acrid. *Flowers* inodorous, in ſeſſile axillary umbels, large and handſome, variegated with green and white, ſtreaked with purpliſh red. *Follicles* three or four inches long, half-ovate, pointed, filled with innumerable imbricated ſeeds.

HOLOSTEUM, has been ſuppoſed by ſome authors to have been derived from ὅλος, *the whole*, and οςεον, *bony*, thus, by antiphraſis, alluding to its extreme delicacy and tenderneſs of ſtructure. An attentive peruſal of Dioſcorides ſeems rather to favour a different explanation, for he ſpeaks of his ὁλοςεον as a conſolidating herb, which its name, from ὅλος, or ὅλος, *entire*, *ſane*, or *perfect*, might poſſibly imply. Linn. Gen. 42. Schreb. 57. Willd. Sp. Pl. v. 1. 488. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. v. 1. 161. Juſſ. 299. Lamarck. Dict. v. 3. 135. Illuſtr. t. 51. Gærtn. t. 130.—Claſs and order, *Triandria Trigynia*. Nat. Ord. *Caryophyllei*, Linn. *Caryophylleæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of five, ovate, permanent leaves. *Cor.* Petals five, unequally jagged, obtuſe, all equal in length. *Stam.* Filaments three, thread-ſhaped, ſhorter than the corolla; anthers roundiſh. *Piſt.* Germen nearly round; ſtyles three, thread-ſhaped; ſtigmas rather obtuſe. *Peric.* Capſule of one cell, ſomewhat cylindrical, gaping at the top. *Seeds* ſix, or more, roundiſh.

Eſſ. Ch. Calyx five-leaved. Corolla of five unequally-jagged petals. Capſule nearly cylindrical, burſting at the top.

Obſ. The petals of *Holoſteum* are deſcribed by authors in general as bipartite, or deeply cloven, and ſometimes trifid; but Dr. Smith has ſuggeſted (in his Prodromus Floræ Græcæ, v. 1. 303.), that the *petala eroſa*, if conſtant to this genus, as he ſuſpects they are, may afford an excellent eſſential mark. Schreber has obſerved, that in *Holoſteum umbellatum* the petals are doubly or triply toothed, and in *ſucculentum* they are deſcribed as ſubtrifid. In *cordatum* we find them ſometimes ſlightly emarginate, ſometimes entire, in the ſame flower. In Swartz's *diandrum* they are ſaid to be deeply divided.

1. *H. cordatum.* Linn. Sp. Pl. 130. (Alſine americana, nummulariæ folio; Herm. Parad. Batav. t. 11.)—Leaves nearly heart-ſhaped. Stipulas four on each ſide.—Native of Jamaica and Surinam.—*Stems* decumbent, creeping, roughiſh at the lower part. *Leaves* oppoſite, roundly cordate, ſmooth, almoſt ſeſſile. *Stipulas* membranaceous. *Peduncles* lateral, elongated, aſcending, about ſeven-flowered, the partial ſtalks falling with the fruit when ripe.

2. *H. diandrum.* Willd. n. 2. Swartz. Prod. 27. Ic. t. 7.—Stems procumbent, rather rigid. Leaves roundiſh. Flowers diandrous. An inhabitant of Jamaica.—*Radicles* capillary, whitiſh. *Stem* much branched, ſtraight, ſmooth. *Leaves* oppoſite, entire. *Stipulas* hairy, at the baſe of the flower-ſtalks. *Capſule* roundiſh, or ſlightly triangular.—Profeſſor Swartz remarks that this is diſtinct from the laſt ſpecies, being altogether a much ſmaller plant; but upon comparing his plate with the Linnæan ſpecimen of *H. cordatum*, it appears that the latter is extremely variable in ſize, and therefore this circumſtance is not ſufficient to make them diſtinct ſpecies. Neither are the diandrous flowers a proper diſtinctive mark, becauſe *H. umbellatum* frequently varies in having from three to ten ſtamens.—We, therefore, only adopt this ſpecies on the authority of Swartz. The *petals* of *H. cordatum* are often as deeply divided as thoſe of *diandrum* are repreſented.

3. *H. ſucculentum.* Linn. Sp. Pl. 130. Amœn. Acad. v. 3. 21.—"Leaves elliptical, fleſhy."—Native of New York.—*Flowers* white; petals ſubtrifid, ſmaller than the calyx.

4. *H. hirſutum.* Linn. Sp. Pl. 130. Amœn. Acad. v. 3. 21.—"Leaves orbicular, hairy."—A native of Malabar.—There are no ſpecimens either of this or the laſt ſpecies in the Linnæan Herbarium, nor are they any where figured.

5. *H. umbellatum.* Linn. Sp. Pl. 130. Engl. Bot. t. 27.—"Flowers in umbels."—This is rather a ſcarce plant, found on old walls, flowering early in the ſpring.—It was firſt detected in England by Mr. Pitchford in the year 1765, on walls in the neighbourhood of Norwich.—The *plant* is in general ſmooth, ſomewhat glaucous. *Stem* branching at the baſe, towards the top hairy and viſcid. *Leaves* oppoſite, ovate, acute. *Umbel* ſimple, terminal. *Peduncles* bracteated, divaricated when the fruit is ripe. *Flowers* white or bluſh-coloured. *Capſule* ſix-toothed. *Stamens* varying from three to ten in number.

This is the only Britiſh ſpecies of *Holoſteum.* It approaches very cloſely in habit to *Ceraſtium*, and was placed in that genus by Mr. Hudſon; but its petals being unequally jagged, and not bifid, warrant its continuance in *Holoſteum.*

HOLOTHURIA, in *Zoology*, a Linnæan genus of the Molluſca tribe of worms, the body of which is detached, cylindrical, thick, naked, open at the extremity, and the mouth ſurrounded by fleſhy tentacula or feelers.

This character aſſociates in the ſame family a number of animals ſo different in form, that it appears ſcarcely poſſible to admit the genus without ſome further modification. It is true that all the ſpecies referred to it by Linnæus and Gmelin are not deſcribed with equal accuracy by their reſpective obſervers, and this conſideration ſhould induce us to ſpeak with caution as to the propriety of reducing ſome particular kinds to the new genera propoſed by ſubſequent authorities. This is not, however, the caſe with all; many have been examined in their native element, and in a living ſtate with unqueſtionable care, and their organization explained in a ſatisfactory manner; upon theſe, therefore, we are enabled to pronounce an opinion, and confining our attention to theſe only we cannot heſitate to believe that the Linnæan holothuriæ are diviſible in a natural arrangement into three, if not a greater number, of diſtinct genera.

The laſt edition of the "Syſtema Naturæ" contains altogether twenty-three ſuppoſed ſpecies of the holothuria, but it is to be obſerved that Gmelin himſelf affixes ſome mark of doubt as to the identity of the true genus to which certain kinds belong; and this not without reaſon, ſince it is clear their eſſential character cannot be reconciled with the natural character of the holothuria tribe in general.

Perhaps Linnæus, in the eſtabliſhment of his genus holothuria, rejected the ideas of Forſkal without ſufficient conſideration. Forſkal, we find from the reſult of his own obſervations on the vermes found in the Arabian ſeas, conceived he had diſcovered, among others, two natural families of theſe marine bodies, and propoſed for their reception the inſtitution of two new genera, to which he applied the ſignificant appellatives of priapus and fiſtularia; theſe Linnæus conſigned to his genus holothuria, and in conſequence moſt probably of his example thoſe genera have never been adopted.

Again, the thalia or thalis genus, ſuggeſted by Brown, is conſolidated by Linnæus with the holothuria. It is probable we may not at preſent ſo clearly underſtand the thalis tribe as to be enabled to form a very poſitive concluſion as to its eſſential characters, though we may, nevertheleſs, obſerve, that it does not ſeem to appertain to the holothuria tribe, being more cloſely allied to that of ſalpa. The obſervations of Boſc are calculated to prove the animals of the thalis kind to be truly ſalpæ, and which, if accurate, muſt occaſion the removal of ſome Gmelinian ſpecies of the holothuria to that genus, as the thalia, caudata, and denudata. Lamarck, however, conceives them equally diſtinct from the holothuriæ and the ſalpæ, and for this reaſon re-eſtabliſhed the genus thalis as originally propoſed by Brown.

As to the propriety of adopting the genus phyſalidis there cannot, we imagine, be any difference of opinion; it is evidently diſtinct from the holothuria.

And, laſtly, we ſhould mention the genus velella, one of thoſe newly inſtituted by the French naturaliſts, and which tends to unite the holothuriæ with the meduſæ by forming an intermediate link between them, and ſtill connecting both. The genus contains two ſpecies, namely, the Velella mutica referred by the Linnæan claſſification to the meduſa tribe under the ſpecific name of velella, and the holothuria tentaculata of Forſkal.

Having pointed out the number of new genera into which the Linnæan holothuriæ are divided by later naturaliſts, it will be proper to ſtate in what material particulars their eſſential characters differ from each.

The true holothuriæ have the body detached, cylindrical, thick, very contractile, with a coriaceous ſkin, and having at the extremity a mouth armed with five calcareous teeth, and a radiation of ramoſe or pinnate tentacula. The genus thalis has the body detached, gelatinous, oval, or oblong, compreſſed at the ſides, and the back either deſtitute of the creſt, or furniſhed only with a very ſhort one, and placed near one extremity; no tentacula under the belly. In the phyſalidis or phyſalia, the body is detached, membranaceous, or gelatinous, oval, compreſſed at the ſides, the back furniſhed with a creſt, and the under part of the belly with a great number of diverſely formed articulated tentacula of different lengths, apparently ſuckers. The body of the velella is detached, elliptic, cartilaginous within, the exterior part gelatinous, and having upon the back an elevated truncated creſt placed obliquely; the mouth beneath and ſituated in the centre. According to the above characters the Gmelinian ſpecies, elegans, pentactes, and priapus: forcipata of O. Fabricius; zonaria of Pallas; and maxima of Forſkal are all of the holothuria genus. The three kinds deſcribed by Brown, thalia, caudata, and denudata, conſtitute the genus thalis. The Linnæan ſpecies phyſalis (Phyſalis pelagica of Oſbeck) is the only example of the genus phyſalidis. And the holothuria tentacula of Forſkal is the velella.

Theſe animals are of the marine kind, and in general ſuppoſed to be viviparous; they live on ſmall fiſhes, worms, teſtaceous bodies, &c. and are uſually diſtinguiſhed by the ſplendour of their colours.

Species.

Elegans. With twenty branched tentacula; body papillous, reddiſh above, beneath white. Müll. Stroem. Sondm. &c.

Inhabits the ſeas of Denmark and Norway; the length from eight to eleven inches; body varied with red and white; papillæ pointed, and diſtant, thoſe on the back diſpoſed in ſix ſeries; tentacula fleſhy, and white, the tip furniſhed with a tuft of fibres which are tuberculated within. Squirts out water like a ſiphon from the lower orifice.

Frondosa. Tentacula frondoſe; body ſmooth. O. Fabr.

The body ovate; beneath flat, with ten retractile tentacula; the poſterior part conic, perforated at the end. Found in the northern ſeas.

Phantapus. Tentacula branched; poſterior part of the body attenuated; beneath rough with dots. Müll. *Holothuria phantapus,* Linn. *Pudendum miſſum,* &c. Aldr. Geſn. &c.

Native of the Norway and Mediterranean ſeas. The body is ovate, beneath flat; behind conic, with the tip perforated, tentacula 10, and retractile.

Tremula. Tentacula faſciculate; body covered above with numerous ſub-conic papillæ, beneath with cylindrical ones. *Holothuria tremula,* Linn. *Holothuria tubuloſa,* Gmel. *Holothurius Rondeletii,* Jonſt. *Epipetro zoographi ſimile,* Aldr. *Genitale marinum,* Bell. *Pudendum regale piſcatorium,* Column. *Mentula marina,* Plancus. *Fiſtularia,* Forſk.

Found in the Mediterranean and Adriatic ſeas. Length one foot; the body cylindrical when extended, and oblong when contracted, generally a beautiful mixture of red and white, but it varies in colour; the cylindrical tubes beneath the body act as ſuckers, by means of which it adheres to the rocks.

Physalis. Cirri filiform, pendulous, and of different ſhapes. Linn. *Urtica marina,* Sloane. *Arethuſa criſtata,* &c. Brown. *Phyſalis pelagica,* Oſbeck.

Inhabits the Atlantic ſeas, where it is often ſeen floating in calm weather on the ſurface of the water, and is known to mariners by the name of the Portugueſe man of war; the form ovate, ſomewhat triangular, and hyaline; back acute and duſky green; anterior part reddiſh; ſnout ſpiral and reddiſh; tentacula numerous, unequal, ſome round, thick and ſhort; ſome capillary, with a globular yellow tip, others longer and filiform.

Thalia. Creſt compreſſed; lateral lines entire. Gmel. *Thalia oblonga,* &c. Brown. Jam.

Native of the American and Weſt India ſeas.

Caudata. Tailed; creſt compreſſed; lateral lines interrupted. Gmel. *Thalia oblonga, caudata,* &c. Brown.

Inhabits the American ſeas.

Denudata. Deſtitute of creſt and tail. Gmel. *Thalia,* &c. Brown.

The body of this ſpecies is oblong, rounded, and gradually tapering to both extremities; the length from three to four inches, diameter one inch; tranſparent, and hollow; the anterior opening triangular, the other rounded. Native of the American ſeas.

Pentactes. With ten ramified tentacula; body with five rows of papillæ. Müll. *Cucumis marinus,* Geſn. *Cucumer marinus,* Vandell. *Aphrodita quarta,* Hill. *Brimbatus,* Olaff. *Fleurilarde,* Dicquemar.

Length ſix inches; the body greeniſh-brown; tentacula elegantly ramified, of a yellow and ſilver colour; the filaments with ſmall retractile filaments iſſuing from them. Inhabits the ſeas of Europe.

Papillosa. With ten frondoſe tentacula; body ovate, and covered every where with papillæ. Müll. Inhabits the bays of the North ſeas.

Spallanzani. With ninety-ſix filamentous tentacula. Spallanz. Native of the Mediterranean.

Priapus. Mouth with fleſhy papillæ; body with annular ſtriæ, and longitudinal ones on the gland. O. Fabr. *Priapus,* Linn.

Inhabits the Indian and Mediterranean ſeas; the length ſix inches. One half of the body cylindrical, with numerous annular ſtriæ, and terminated by the mouth; the other half obovate and gland-ſhaped, with twenty-four longitudinal parallel elevated, diſtant, rough ſtriæ; the aperture concave, and ſurrounded by an excavated annular ſtria, and furniſhed within with numerous recurved ſpines.

Squamata. With eight ſlightly branched tentacula; body rough above, beneath ſoft. O. Fabr., &c. *Actinia ſquamata,* Nov. Act. Nat. Cur. *Aſcidia ſquamata,* Pallas.

Native of the Norway and Greenland ſeas; the ſpecies varies in ſize, and adheres firmly to rocks.

Penicillus. With eight branched tentacula; body bony, and five-ſided. Müll.

Lives in the mud in the deeps of the Northern ſeas; the body is immoveable, ventricoſe, ſmooth, white, with a brown collar black at the edges, and a parallel granulated pale ring behind the tentacula, which are carinated and blackiſh-yellow.

Fusus. With ten tentacula; body fuſiform and downy. Müll.

Like the laſt, inhabits the mud in the deeps of the Northern ſeas. The body is cinereous, rough with minute ſcales, and beſet with very ſhort fibres; protruding a cup-ſhaped hollow body, furniſhed beneath with a neck, and dilated above into an orb, perforated in the middle, with a black foramen, tentacula denticulated at the ſides.

Inhærens. Body brown, with longitudinal whitiſh ſtripes, and twelve red tentacula. H. *Inhærens,* Müll. *Fiſtularia reciprocans,* Forſk.

Native of the North and Red ſeas; the body long, narrow, pellucid, and covered with innumerable viſcid papillæ, by means of which it ſticks to whatever it touches; tentacula fleſhy, lanceolate, and denticulated, or ſlightly branched each ſide.

Lævis. Elongated, with white tentacula; body with five rows of lines and dots. O. Fabr.

Inhabits the Greenland ſeas, reſiding among rocks, and frequently hiding itſelf in the clay, from whence each alternate tentacula is protruded, while the reſt are contracted; the body is ſoft, ſmooth, whitiſh and pellucid; the length from one to ſix inches; tentacula whitiſh, ſoft, and eight-cleft at the tip.

MINUTA. Oblong, with twelve tentacula; body with five rows of warts. O. Fabr.

Found in the ſame ſeas as the latter, in ſandy bottoms, and moves very ſlowly by means of its extended papillæ. The body four lines in length, glabrous, ſub-membranaceous, whitiſh, and rarely red; each row of papillæ conſiſting of ten; tentacula yellowiſh and ſix-cleft at the tip.

FORCIPATA. Ventricoſe, both ends narrow and conic; the anterior one forcipated. O. Fabr.

Length five inches; the body ſoft, lubricous, with a thin ſkin covered with innumerable ſlightly raiſed dots; forceps rigid, ochrey yellow, with curved fangs. Inhabits clayey bottoms in the Greenland ſeas, and is often devoured by the ſea ſcorpion, Cottus ſcorpio.

ZONARIA. Oblong, depreſſed, with a fleſh-coloured ſheath, and a whitiſh hyaline pouch; body encircled with five yellow zones. Pallas.

Mouth tranſverſe, with prominent gaping lips; inhabits the ſeas about Antigua.

VITTATA. Body ſoft, lax, with white bands dotted with brown; tentacula linear-lanceolate, and toothed at the ſides. Forſk.

The body with five white ſtripes dotted with black, and alternate narrow brown ones dotted with white; tentacula twelve, brown in the middle, and at the ſides paler. Inhabits the Red ſea, among zoiteræ, and adheres to the hands by means of its viſcid papillæ; length a ſpan and a half.

MAXIMA. Body rigid and nearly ſquare; above convex, beneath flat, and edged with white; tentacula filiform, and cut like petals at the tip. *Fiſtularia maxima*, Forſk.

The body about a foot in length, hard, and rough with papillæ; tentacula grey hyaline. Native of the Red ſea.

IMPATIENS. Body rigid and cinereous; tentacula twenty, filiform, ſeven-cleft, and denticulated at the tip. *Fiſtularia impatiens*, Forſk.

Inhabits the ſhores of the Red ſea under ſtones, or in the pores of Spongia officinalis. The body hardiſh, cinereous, varied with ſpots and bands, and rough with hemiſpherical warts, whitiſh in the middle, and contiguous; tentacula hyaline dotted with black, and obtuſely toothed.

NUDA. Orbicular, blue, without creſt; tentacula of the diſk naked; of the rays beſet with three rows of glands. Gmel. *Holothuria denudata*, Forſk.

About an inch in diameter; the body whitiſh in the diſk above, and radiated with concentric ſtriæ, the margin and border blue; tentacula filiform and blueiſh hyaline. Cloſely allied to the meduſa.

SPIRANS. Oval, blue, with oblique divided creſt or veil, and numerous tentacula beneath. Gmel. Forſk.

Native of the Mediterranean; the body thin, convex, and terminating in a whitiſh central protuberance above, blue with brown border; creſt two-parted and ſtriated; tentacula filiform. Length two inches.

TENTACULATA. Oval; tentacula ſurrounding the mouth white. Forſk, &c. An ambiguous ſpecies.

HOLOWNE, in *Geography*, a town of Poland, in the palatinate of Chelm; 28 miles N.E. of Chelm.

HOLQUAHVILT, in *Botany*, a name by which ſome authors have called the tree which produces the Jeſuit's bark.

HOLRAS, in *Geography*, a town of Norway, in the dioceſe of Chriſtianſand; 12 miles S.W. of Chriſtianſand.

HOLRU, a town of Abyſſinia; 65 miles S. of Minè.

HOLSANOE', a ſmall iſland in the N. ſea, near the coaſt of Norway. N. lat. 60° 32'.

HOLSMUNSDEN, or HOLTZMUNDEN, a town of the principality of Wolfenbuttel, on the Weſer; 21 miles W. of Eimbeck.

HOLSOM. A ſhip is ſaid to be holſom at ſea, when ſhe will hull, try, and ride well, without rolling or labouring.

HOLSTABROC, in *Geography*, a town of Denmark, in North Jutland, ſituated on a river, which runs into the North ſea. The trade of the inhabitants chiefly conſiſts in corn, oxen, and horſes; 24 miles W. of Wiborg. N. lat. 56° 22'. E. long. 9° 38'.

HOLSTEIN, DUCHY OF, a country of Germany, in the circle of Lower Saxony. Including the lordſhip of Pinneberg, it is bounded on the N. by the duchy of Sleſwic and the Baltic, on the E. by the Baltic, on the S. by the duchy of Lauenberg, the territories of Lubeck and Hamburg, and the Elbe; and on the W. by the Elbe and the German ſea. It is about 70 miles long from E. to W., and 48 broad from N. to S. Subject to frequent ſtorms and conſequent inundations from its ſituation between the Baltic and the German ſea, its inhabitants are put to great expence in raiſing dykes, particularly in the diſtricts bordering on the German ſea and the Elbe. Theſe diſtricts conſiſt of excellent marſh land, which produce wheat, barley, oats, beans, peas, and rape-ſeed in great plenty. The meadows and paſtures feed great numbers of cattle. The other parts of the country are ſtill more fertile.

Holſtein is divided into four provinces, *viz.* Holſtein Proper, Stormar, Ditmarſen, and Wagria; the three firſt of which were formerly called "Nordalbingia," or "Saxony beyond the Elbe." The Saxons of this country were a free people, till Charlemagne ſubdued them, and removed 10,000 families into Brabant, Flanders, and Holland. By a treaty between this ſovereign and the king of Denmark, the river Eider was fixed as a common boundary of the two countries. The country on the S. of the river was called the Marche, and a marggrave was appointed to defend it. Holſtein Proper and Stormar were erected into a county by Lothario, duke of Saxony, in 1106, in favour of the count of Scauenburg; and his ſon Adolphus II. incorporated Wagria with Holſtein, and peopled the territory with ſtrangers from Holland and Weſtphalia. The territories were afterwards divided into ſeparate principalities; and one of the princes who reigned here obtained from the king of Denmark the inveſtiture of Sleſwick. When this branch became extinct, and the people elected Chriſtian I. king of Denmark, he became duke of Sleſwick, and count of Holſtein, which was ſoon afterwards erected into a duchy. His poſterity reigned here as well as in Denmark. In 1720 the reigning prince of Holſtein Gottorp, founded by the ſecond ſon of Frederick I., was entirely diſpoſſeſſed of his dominions. This prince had eſpouſed Ann, the eldeſt daughter of Peter I. emperor of Ruſſia. In 1743 his ſon, Charles Ulric was, by his mother's ſiſter, Elizabeth, empreſs of Ruſſia, declared grand duke of Ruſſia. The king of Denmark, as duke of Holſtein Gluckſtadt, had formerly a ſeat and voice in the diet of the empire in the college of princes; and the emperor or empreſs of Ruſſia poſſeſſed the ſame prerogatives for Holſtein Gottorp. To the king of Denmark it belonged to appoint a governor over his part of Holſtein, whoſe uſual reſidence was Gluckſtadt, whilſt the regency court for Ruſſian Holſtein was held at Kiel. The principal trading towns are Altona, Gluckſtadt, and Kiel. The exports of Holſtein are wheat, barley, malt, ſtarch, buck-wheat, peas, beans, rape-ſeed, horned cattle, ſheep, rams, ſwine, horſes, poultry, butter, cheeſe, veniſon, and fiſh. Lord Moleſworth obſerves, that Holſtein very much reſembles England; and another traveller has remarked, that the inhabitants are in their perſons very like the Engliſh. Hence it has been inferred, that the Engliſh nation came firſt from this lower circle of Saxony; and in confirmation of this conjecture, it is alleged, that there is an ancient town near it, called Landen, and an iſland called Angles, which gave occaſion to call our Britannia, Anglia. This remark is confirmed by the moſt diligent inquirers into this ſubject, who place the country of our Saxon anceſtors in the Cimbric Cherſoneſe, in the tracts of land ſince known by the names of Jutland, Angelen, and Holſtein.

HOLSTON, a river of America, being a branch of the Teneſſee, which riſes in Virginia, and joins the Teneſſee, 22 miles below Knoxville. At that town it is 300 yards wide, and in a courſe of about 200 miles in length it receives ſeveral conſiderable rivers and ſmaller ſtreams. It is navigable for boats of 25 tons upwards of 100 miles, to the mouth of the N. Fork, where iron-works have been erected upon a large ſcale.—Alſo, a ſettlement on this river, in the ſtate of Teneſſee, containing, in 1790, 28,649 inhabitants. The land is generally fertile, and being ſituated between two mountains, it ſeldom ſuffers for want of rain. It abounds with iron ore. A capital furnace and forge have lately been erected in Holſton, near the Virginia line, a bloomary below the mouth of Watawga, and another 25 miles above the mouth of the French Broad. There are ſeveral lead mines in the ſettlement, and one particularly on the French Broad, that produces 75 *per cent.* pure lead. Merſe.

HOLSTENIUS, or HOLSTEIN, LUKE, in *Biography*, was born at Hamburg in 1596. Having received a liberal education in his own country he went to Paris, where he acquired a high reputation for learning, but was converted from the principles of Lutheraniſm, in which he had been brought up, to thoſe of Popery. He went from Paris to Rome, where he obtained the patronage of cardinal Francis Barberini, and through his means received diſtinguiſhed marks of favour from the popes Urban VIII., Innocent X, and Alexander VII. By the firſt he was made canon of St. Peter's; by the ſecond librarian of the Vatican; and by Alexander VII. he was ſent to Inſpruck, where he received from queen Chriſtina of Sweden her formal profeſſion of the Chriſtian faith. He died at Rome in the year 1661, leaving behind him a high character for deep learning, a ſound and penetrating judgment, and a fine critical taſte. He was editor of a number of very learned works which he illuſtrated with notes and diſſertations; and he left behind him much valuable matter, which was given to the public after his death, by his friends, in their editions of authors, or in different collections. Among his other pieces was "The Life of Pythagoras, by Porphyry," in Greek and Latin, with a curious diſſertation on the life and writings of Porphyry, and obſervations on the life of Pythagoras. Moreri.

HOLSTER, a caſe for a horſeman's piſtol.

HOLSWORTHY, in *Geography*. See HOLDSWORTHY.

HOLT, when it occurs at the beginning or end of a word, ſignifies that it is, or hath been woody, from the Saxon holt, *a wood*, or ſometimes poſſibly from the Saxon hol, *hollow*. Johnſon.

HOLT, *Sir* JOHN, an eminent lawyer and judge, ſon of ſir John Holt, ſerjeant at law, was born at Thame, in Oxfordſhire, in 1642. He received the firſt principles of learning at Abingdon, of which town his father was at that time recorder: he afterwards went to Oriel college, Oxford, and from thence was entered a ſtudent at Gray's Inn. He ſoon became diſtinguiſhed as a barriſter, and in the reign of James II. he was made recorder of London, ſoon after which he was called to the degree of a ſerjeant of the law. By refuſing to give aſſiſtance to the arbitrary meaſures of the king, he was removed from the recorderſhip of the city, but he retired with the approbation of an honeſt mind, and the regrets of the people, of whoſe cauſe he was always the advocate in ſpite of the authority and influence of the court. His principles were too well known for him to be forgotten in times of emergency, and he was choſen member of the convention parliament in 1688, and he was appointed one of the managers for the commons at the conferences held concerning the vacancy of the throne. In 1689 he was raiſed to the dignity of lord chief juſtice of the king's bench, and admitted to the honour of privy counſellor. He refuſed the poſt of chancellor offered him at the death of lord Somers, and continued as chief juſtice till his death in 1709. He is memorable among the Engliſh judges for a thorough knowledge of the law, joined to an invincible firmneſs and reſolution in ſupporting its authority. He held in contempt the aſſumed powers of a houſe of commons, when thoſe powers were evidently hoſtile to the common law of the land. He was the intrepid aſſertor of the rights and liberties of the ſubject, and was remarkably jealous of the interference of the military power in the execution of the laws: of which he gave a very ſignal proof when applied to ſanction, by the preſence of one of his people, the proceedings of the military ſent to quell a riot excited by the infamous practice of crimping. The chief juſtice aſked the officer what he intended to do if the populace refuſed to diſperſe, he replied, "we have orders to fire upon them:" "Have you ſo?" ſaid the judge, "then obſerve, if one man is killed, I will take care that you and every ſoldier of your party ſhall be hanged. Sir, acquaint thoſe who ſent you, that no officer of mine ſhall attend ſoldiers, and let them know, likewiſe, that the laws of this land are not to be executed by the ſword. Theſe things belong to the civil power, and you have nothing to do with them." Such patriotic and virtuous conduct as this chief juſtice ever manifeſted, has not frequently been found in perſons filling that high office. Few inſtances, indeed, have been found, in which judges have not acted the upright and honourable part in all cauſes of individuals brought before them; they have no motive to act otherwiſe: but the inflexible integrity of a judge is brought to the teſt when great political queſtions are to be decided: when one of the people, who is but as duſt in the balance, is about to be borne down by a whole branch of the legiſlature, in ſuch a caſe lord chief juſtice Holt was tried, and his deciſion has inſured for him an unfading immortality. Britiſh Biog.

HOLT, in *Geography*, a market town and pariſh in the hundred to which it gives name, in the county of Norfolk, England, is pleaſantly ſituated on an eminence, 121 miles diſtant from London. Great part of the town was deſtroyed by fire in the year 1708, ſince which time many good houſes have been erected. The enumeration under the late act of parliament was 215 houſes, and 1004 inhabitants. The quarter-ſeſſions of the peace are holden here, by adjournment from the city of Norwich. The ſeſſions-houſe, which is a handſome building, is occaſionally uſed for holding ſubſcription aſſemblies. A conſiderable free-ſchool was founded here, in the year 1556, by ſir Thomas Greſham, who was a native of this town, and whoſe memory is perpetuated by the building of the royal exchange, London. The ſchool is well endowed for 30 ſcholars, and has annexed to it a ſcholarſhip and fellowſhip in Sydney college, Cambridge. The patronage and government of the ſchool are, by the appointment of the founder, veſted for ever in the company of fiſhmongers of London. Two fairs are annually held here;

and a weekly market on Saturday. Blomefield's Hiſtory and Antiquities of Norfolk.

Holt, a townſhip and chapelry in the pariſh of Greſford, and hundred of Bromfield, Denbighſhire, Wales, is ſeated on the banks of the river Dee, and was formerly a market town. At this place the river ſeparates England from Wales, the county of Cheſter being on one ſide, and that of Denbigh on the other. Theſe are united by a bridge of 10 arches, which is ſaid to have been built in the year 1345. On the banks of the river formerly ſtood a ſtrong caſtle, which is now nearly levelled to the ground. It was garriſoned for Charles I. in 1643, but, with other fortreſſes in this part of the country, was taken by the parliamentary forces. The inhabitants of Holt, Denbigh, and Ruthin, jointly ſend one member to parliament. In 1801 this townſhip contained 161 houſes and 804 inhabitants. Pennant's Tour in Wales, vol. i. 4to.

Holt, a town of Norway, in the dioceſe of Chriſtianſand; 32 miles N.N.E. of Chriſtianſand.—Alſo, a town of Germany, in the duchy of Cleves; 27 miles S.E. of Cleves. N. lat. 51° 39′. E. long. 6° 26′.

Holt, a village of England, in the county of Wilts, ſeven miles E. of Bath; it has a medicinal ſpring.

Holt, in *Rural Economy*, the name of a morbid affection of the feet of different domeſtic animals. The hoof and feet in this caſe ſhould be carefully examined, and the cauſe aſcertained.

Holt-*waters*. Theſe have been found by experience to be of admirable efficacy in all ſcorbutic and ſcrophulous caſes. An account of ſome very remarkable cures performed by them in theſe caſes, was printed ſeveral years ago; and though known to be fact in the place, was diſbelieved by almoſt every body beſide.

Mr. Lewis, formerly miniſter of the place, confirms their efficacy from his own obſervation; and obſerves that they are of an attenuating, aſtringent, and drying nature. The firſt of theſe properties they poſſeſs in common with all waters which dilute, attenuate, and fit the juices for paſſing the proper veſſels; their aſtringency they owe to the alum and iron which they contain; and their drying, abſorbing, and healing qualities are probably owing to a quantity of ſulphur, and a fine light ochre, which they are impregnated with. Phil. Tranſ. N° 408.

Holt's *Creek*, in *Geography*, a river of America, in the ſtate of Kentucky, which runs into the river Kentucky, N. lat. 38° 37′. W. long. 84° 18′.

HOLTALEN, a town of Norway, in the dioceſe of Drontheim; 54 miles S. of Drontheim.

HOLTEN, a town of Norway, in the government of Aggerhuus, remarkable for its church, which is cut out of a rock; it is very ancient, and ſuppoſed, by Olaus Wormius, to have been an heathen temple; 15 miles N.W. of Tongſberg.

HOLTZBAUER, in *Biography*, in 1772 maeſtro di cappella to the elector palatine at Manheim, when his electoral highneſs had the beſt inſtrumental band in Europe, and operas compoſed expreſsly for his theatre by the greateſt maſters of the time. Holtzbauer, who had been in Italy, was not only an excellent compoſer of ſymphonies on the model of the elder Stanitz, but the opera ſinging-maſter. The Danzi, afterwards Madame Le Brun, and the Allegranti, were his ſcholars.

HOLTZBOGN, an excellent performer on the violin in the ſervice of the elector of Bavaria, in 1772. He was a ſcholar of Tartini, had a great hand, a clear tone, and more fire than was uſual in performers of the Tartini ſchool, which was rather remarkable for delicacy, expreſſion, and high-finiſhing, than for ſpirit and variety. Holtzbogn wrote well for his inſtrument, and we heard him play a very maſterly concerto of his own compoſition.

HOLTZHAUSEN, in *Geography*, a town of Germany, in the biſhopric of Munſter; 8 miles N.W. of Munſter.

HOLTZKIRCHEN, a town of Bavaria; 18 miles S.S.E. of Munich.

HOLUAN, Holwan, or *Hulvan*, a town of the Arabian Irak; 110 miles N.N.E. of Bagdad. N. lat. 34° 50′. E. long. 44° 54′.

Holuan, a town of Egypt, on the right bank of the Nile; 12 miles S. of Cairo.

HOLUM, or Hoalum, or *Hola*, a town of Iceland, at the mouth of a ſmall river, the ſee of a biſhop, founded about the year 1106, and ſince improved by Chriſtiern III. Here are a ſchool, cathedral, and printing office. N. lat. 65° 43′. W. long. 15°.

HOLWELL, John Zephaniah, in *Biography*, was born about the year 1709. He went out in early life as a writer in the ſervice of the Engliſh Eaſt India company, and by his aſſiduity he gradually roſe in office till the year 1756, when he was appointed ſecond in council at Fort William. At this period, an offence having been given to the nabob of Bengal, induced him to lay ſiege to that fort with a powerful army. The governor fled, and the command devolved on Mr. Holwell, who, with a few men, was reſolved to defend the place to the laſt extremity. He was, however, obliged to ſurrender, but on the promiſe of ſecurity to their perſons, in violation of which he and his men were ſhut up in a ſmall room, ſince denominated the *black*-hole of Calcutta, which ſee. Of the ſurvivors who eſcaped this infernal charnel-houſe, Mr. Holwell was one, who became the hiſtorian of the ſufferings which were endured on that occaſion; and when Calcutta was brought under the Britiſh dominion he raiſed a monument on the ſpot, at his own expence, to the memory of the unhappy victims, and to record the infamy of him who could perpetrate ſo black a deed. On his return to England Mr. Holwell wrote various tracts upon the concerns of the India company, and he entered deeply into the hiſtory and mythology of the natives of Hindooſtan, concerning which he gave the public ſome curious information in a work entitled "Intereſting hiſtorical Events relative to the Provinces of Bengal and the Empire of Indoſtan." In this he gives a very particular account of the Gentoo Shaſtah, which he repreſents as the oldeſt religious inſtitute extant, and the genuine ſource of the mythology and coſmogony of the Egyptians, Greeks, and Romans. He publiſhed another work, in 1788, connected with this ſubject, entitled "Diſſertations on the Origin, Nature, and Purſuits of Intelligent Beings," &c. The idea that men are fallen angels, condemned to ſuffer in human bodies for the ſins of their former ſtate, is the leading principle of this production. Mr. Holwell was author of ſeveral other pieces, one on inoculation for the ſmall-pox in the Eaſt Indies, with the mode of treating the diſeaſe in that part of the world, and one entitled "A new Experiment for the Prevention of Crimes," which chiefly conſiſts in propoſed premiums for the practice of virtue. He died in 1798, much reſpected by all who knew him. His works diſplay a benevolent heart, and a liberal way of thinking. There is ſtill living, at a very advanced age, in the neighbourhood of London, Captain Mills, one of the fellow ſufferers with Mr. Holwell in the black-hole of Calcutta.

HOLY, haliz, Saxon, or *heyleigh*, Dutch, from hal, *healthy*, or in a ſtate of ſalvation. The term is variouſly applied; ſometimes in the ſame ſenſe with good, or religious, or ſacred, and ſometimes for hallowed, or appropriated to religious or ſacred purpoſes. Thus, it is uſed in the ſame ſenſe with ſanctified, *i. e.* ſeparated from ordinary uſe, and appropriated to pious or religious purpoſes. In this ſenſe it has been applied to perſons, places, and things. See Holyness.

Holy, *Cape*, in *Geography*, a cape in the Frozen ocean. N. lat. 72° 32′. E. long. 179° 40′.

Holy *Fire*. See Fire.

Holy *of Holies*, called alſo the “moſt holy place,” and the “oracle,” becauſe God here gave his anſwers to the high prieſt, when conſulted by him, an apartment of the Jewiſh temple, which was divided, in the firſt temple, from the “holy place” by a partition of boards overlaid with gold, in which there was a door-place with a vail over it. It was 20 cubits in length. Although the “holy place” was reckoned very ſacred, yet it was not to be compared in this reſpect with the “moſt holy,” which was regarded as the palace of God. For this reaſon none but the high prieſt was permitted to go into it, and that but once a year, *viz.* on the great day of expiation (Exod. xxx. 10. Lev. xvi. 2. 15. 24. Heb. ix. 7.), on which day, as the Jews tell us, it was lawful for him to go in ſeveral times. This part of the temple, as well as the whole building, was ſurrounded with rooms and apartments for different uſes. The roof of the “holy of holies” was not flat, as in the other parts of the temple, and in eaſtern houſes in general, but ſloping, as in our buildings; and, according to Joſephus (De Bell. Jud. l. vi. c. 6.) it was covered and armed all over with pointed ſpikes of gold, to keep off the birds from neſtling upon it. Although the roof was inacceſſible to all, yet there was round it a kind of rail or baluſtrade, according to the law (Deut. xxii. 8.) to keep any one from falling down that ſhould happen to go there. The “holy of holies” was at the weſt end of the temple, and the entrance into it toward the eaſt, contrary to the practice of the heathens. The greateſt ornament of the “holy of holies” was wanting in the ſecond temple, *viz.* the Ark *of the Covenant*, or *Teſtimony*, which ſee.

Holy *Place*, or *Sanctuary*, an apartment of the Jewiſh temple called by the Jews the “outer houſe” (it being ſuch in reſpect of the “holy of holies”), was ſituated between the porch and the moſt holy place, being 20 cubits broad, and 40 in length and height. It had two gates, one of which was called the *leſſer*, through which they paſſed in order to open the *great* gate, which had four folding doors. The ſanctuary was divided from the holy of holies neither by a wall nor gate, but only by a double vail. This is ſuppoſed to have been the vail which was rent in twain at our Saviour's death (Matt. xxvii. 51.), becauſe it was to be of no further uſe. It ſeems to be alluded to in Rev. xi. 19. xv. 5. See Sanctuary.

Holy *Ghoſt, Order of the*, is a military order in France; the principal in point of dignity in that kingdom.

It was inſtituted by king Henry III. in 1579, in memory of three great events happening on the ſame day, or Whitſunday: *viz.* his birth, acceſſion to the crown of France, and election to that of Poland; the order was to conſiſt of a hundred knights only, who, to be admitted, were to make proof of their nobility for three deſcents.

The king was the grand-maſter, or ſovereign, and took the oath as ſuch on his coronation day; whereby he ſolemnly vowed to maintain for ever the order of the Holy Ghoſt; and not to ſuffer it to ſhrink, fall, or diminiſh, ſo long as it ſhould be in his power to hinder it; nor even to attempt to alter or diſpenſe with any of the irrevocable ſtatutes of the order.

The knights were all to wear a gold croſs, hung about the neck by a blue ſilk ribband, or collar, hanging ſcarfwiſe from the left ſhoulder; and the officers and commanders are alſo to wear the ſame croſs, embroidered in ſilver, ſewed on the left ſide of their cloaks, robes, and other upper garments.

Before they received the order of the Holy Ghoſt, that of St. Michael was conferred, as a neceſſary degree, for which reaſon their arms were ſurrounded with a double collar.

The collar of the order, at its firſt inſtitution, was compoſed of fleurs-de-lis or, cantoned with flames of the ſame, enamelled gules, intermixed with three cyphers, or monograms, of gold, compoſed of the letters H and L, enamelled white; which letters were the initials of the inſtitutor's name, and that of his wife Louiſa of Lorrain. Henry IV. altered the cypher into a trophy of arms. Afterwards the collar was compoſed of fleurs-de-lis, cantoned with flames and trophies of arms; and at the bottom hung a gold croſs of eight points, enamelled on the edges white, with a fleur-de-lis or, at each angle, and in the middle a dove. In an oval, on the back of the croſs, was repreſented St. Michael trampling on the dragon, all proper.

Holy *Ghoſt, Order of*. See Dove.

Holy *Ghoſt, Croſs of the*, in *Heraldry*, conſiſts of a circle in the middle of a croſs, and on it the Holy Ghoſt, in figure of a dove: the four arms are drawn narrow from the centre, and widening to the ends, where the returning lines divide each of them into two ſharp points; upon each of which is a pearl.

From the intervals of the circle between the arms iſſue four fleurs-de-lis. This was the croſs worn by the knights of the order of the Holy Ghoſt in France.

Holy *Rood*, in *Geography*, a bay in Newfoundland iſland, at the head of Conception bay.

Holy *Roſe*, or *Rock*-Rose, in *Botany*. See Cistus.

Holy *Sepulchre of Jeruſalem, Knights of the order of the*, an order which, according to ſome, was inſtituted by Godfrey of Bouloigne, on the ſeventeenth day of July, in the year 1099; and, according to others, by his brother Baldwin, ſecond king of Jeruſalem, in the year 1103. The badge of this order was a croſs potent gold, cantoned with four croſſes of the ſame, without any enamel, pendent at the breaſt to a black ribband; and a like croſs embroidered on the left ſide of the white cloak or mantle, which the knights were conſtantly to wear.

Holy *Thiſtle*, in *Botany*. See Centaurea *Benedicta*.

Holy *Thurſday*, is what we otherwiſe call *Aſcenſion day*.

Holy *Week* is the laſt week of Lent, called alſo *Paſſion Week*.

Holy *Year* is ſometimes uſed for the year of *jubilee* (which ſee); and ſometimes for the eccleſiaſtical year of the Jews. See Year.

HOLYCROSS, in *Geography*, a village in the county of Tipperary, province of Munſter, Ireland, remarkable for the ruins of an abbey which belonged to the Ciſtercian order of monks. The lands belonging to this abbey were an earldom, and the abbot, according to Archdall, was ſtyled *earl of Holycroſs*: he was certainly a baron of parliament, and was uſually vicar-general of the Ciſtercian order in Ireland. A particular account of the buildings may be found in Archdall's “Monaſticon Hibernicum;” but it will ſuffice to obſerve here, that they appear to have been very unequal, ſome being built of marble and highly finiſhed, whilſt other parts are miſerably mean. Theſe ruins cover a conſiderable ſpace, near the banks of the river Suire. A pariſh church and a few wretched cabins are the only remains of of a once celebrated place. It is ſeven miles from Caſhel, on the road to Thurles and Nenagh.

HOLYHEAD, a ſea-port, market-town, and pariſh in the iſland of Angleſea, North Wales, ſtands on a peninſula at the weſtern end of the iſle. In the Britiſh language it is called Caer-Gybi, or the fort or caſtle of Gybi. Having been for many years a ſtation for veſſels that ſail between Ireland and England, it has thereby become a place of trade and public reſort. The diſtance from Holyhead to Ireland is twenty leagues ; and for the conveyance of letters, paſſengers, &c. between thoſe places, one packet ſails hence every day in the week excepting on Thurſdays. It generally reaches the oppoſite coaſt in twelve hours ; but in ſtormy or calm weather, the time of the paſſage is very uncertain : ſometimes the veſſel has remained at ſea for two or three days, but when the wind is favourable, the voyage may be performed in ſix, ſeven, or eight hours. The church-yard at this place is a vaſt maſs of rock, cloſe to the ſea, and is environed by a wall. Pennant deſcribed this to be ſeventeen feet high, and ſix thick on three ſides of the incloſure, and on the other ſide it has only a parapet wall, the natural boundary being a precipitous rock. " At each corner of the wall is an oval tower. The maſonry of the whole is evidently Roman : the mortar very hard, and mixed with much coarſe pebble. Along the walls are two rows of round holes, about four inches in diameter, which penetrate them. The uſe of this harbour to the Romans, in the paſſage from various places to the ports of Lancaſhire and that of Cheſter, is very evident. They could not find a better place to run into, in caſe of hard weather, than this, as it projected fartheſt into the Vergivian ſea ; ſo that they could reach it with leſs danger of being embayed than in any other place." (Pennant's Tour in Wales, vol. ii.) In the vicinity of the town, this author viſited and has left us accounts of other antiquities. On the ſummit of the hill called Pen-Caer-Gybi, are ſome remains of an ancient circular building, which Mr. Pennant conjectures was a Roman *Pharos*, or watch-tower. Remnants of a long wall, built without mortar, were found on the ſide of the hill ; and ſome ruins of an edifice, called Capel y Gorlles, were remaining between the town and the mountain. In the town was a religious houſe, ſaid to have been erected in the latter part of the ſixth century. A college was alſo founded here ſoon after the year 1137, by Hwfa ap Cynddelw, lord of Llys-Lliſon. The preſent pariſh church belonged to the college ; but the oldeſt parts of the architecture do not appear to be anterior to the reign of king Edward III. A public ſchool was eſtabliſhed here in 1745. A large inn and hotel, an aſſembly room, and ſome baths have been erected at Holyhead, within the preſent century, and various improvements have been lately made to the town and harbour. The former conſiſts of one principal ſtreet, with ſeveral detached buildings, and according to the population report of 1801 then contained 503 houſes, and 2132 inhabitants. Here is a weekly market on Saturdays. The harbour is formed by cliffs beneath the church-yard, and a ſmall iſland called Ynys-Gybi, on which is a light-houſe. Pennant's Tour. Beauties of England and Wales, vol. xvii.

HOLYNESS, or HOLINESS, ſanctity ; the quality which conſtitutes or denominates a perſon or thing *holy* ; *i. e.* pure or exempt from ſin.

HOLYNESS is alſo uſed in reſpect of perſons and things that are ſacred ; *i. e.* ſet apart to the ſervice of God, and the uſes of religion.

In this ſenſe we ſay, holy days, holy ordinances, the holy Bible, holy Goſpels, holy war, &c. The Roman Catholics call the inquiſition the holy tribunal ; the ſee of Rome, the holy ſee, &c.

Holy oil, holy water, &c. See UNCTION, WATER, &c.

Paleſtine is particularly called the holy land ; and Jeruſalem the holy city. Princes formerly made a practice of going to ſignalize their religion in the Holy Land ; who would have manifeſted the more genuine ſpirit of religion by ſtaying at home. See CROISADE.

In Romiſh countries, one-third part of the year is taken up in holy days, ſaints days, &c. See FEASTS.

Urban VIII. iſſued out an edict in the year 1643 for diminiſhing the number of holy days.

In Scotland they obſerve no ſtated holy days, beſides Sundays.

By a decree iſſued at Paris, April 9, 1802, the feaſts to be celebrated in France, beſides Sundays, are, the nativity of our Saviour Jeſus Chriſt, Aſcenſion day, the Aſſumption of the moſt bleſſed Virgin, and the feaſt of All-ſaints.

HOLYNESS is alſo a title of quality, attributed to the pope, as that of majeſty is to kings.

Anciently the ſame title, holyneſs, was given to all biſhops ; as appears in St. Auguſtine, Fortunatus, Nicholas I., Caſſiodore, &c. St. Gregory compliments ſome of his contemporary biſhops with your beatitude and your holyneſs.

The Greek emperors of Conſtantinople were alſo addreſſed under the title of holyneſs, on account of their being anointed with holy oil at their coronation. Du Cange adds, that ſome of the kings of England have had the ſame attribute ; and that the Orientals have frequently refuſed it to the pope.

HOLY-ROOD DAY, a feſtival obſerved by the Roman Catholics, in memory of the exaltation of our Saviour's croſs. See CROSS and EXALTATION.

HOLY-WATER SPRINKLE, among *Hunters*, ſignifies the tail of a fox.

HOLYWELL, in *Geography*, a market town and pariſh in Flintſhire, North Wales, derives its name from a copious ſpring, or well, which was much frequented in former times by religious devotees, who fancied that its waters were ſupernaturally efficacious in curing certain diſorders and purifying the body. In the preſent day, the ſame ſtream is rendered more uſeful to mankind, by being applied to mechanical and manufacturing purpoſes. It is ſo highly important and ſingular, and its hiſtory ſo illuſtrative of ancient monaſtic ſuperſtition and craft, that it will be intereſting to narrate a few particulars. The legendary origin of the well ſtates, that Wenifred, or St. Wenifrede, was a beautiful and devout virgin, who lived in the early part of the ſeventh century. She was placed under the protection of a relation, who had founded a church here. A young prince, named Cradock, attempted to ſeduce her, but ſhe fled towards the church for ſafety. In her road to this place of ſanctuary, ſhe was overtaken by the prince, who, enraged by diſappointment, ſtruck off her head. " This, like an elaſtic ball, bounded down the hill, through the door of the church, and up one of the aiſles, directly to the altar, where her friends were aſſembled at prayers ; reſting here, a clear and copious fountain immediately guſhed out. St. Beuno ſnatched up the head, and again joining it to the body, it was, to the ſurpriſe and admiration of all preſent, immediately reunited to the body." Such is the monkiſh origin of the well : and when ſuch a miracle was induſtriouſly circulated, it would neceſſarily excite the aſtoniſhment and reverence of the credulous. Not ſatisfied with ſuch fables, the preſent age has aſſigned a natural and probable origin to the ſpring, by aſcribing it to phyſical cauſes. At the foot of a ſteep hill, and from an aperture in a rock, ruſhes forth a torrent of water, which, from its quantity and regularity, is calculated to aſtoniſh the ignorant and intereſt the geologiſt. It has been aſcertained that this ſpring diſcharges not leſs than eighty-four hogſheads of water in a minute. This is never known to freeze, and the current rarely ever varies in quantity; and from its rapid courſe and quantity, it becomes of ineſtimable value; for though the water has only a mile and 124 yards to flow in its progreſs to the ſea, it turned, a few years ago, the machinery to eleven different extenſive mills. Theſe appertained to ſo many manufactories, &c. for cotton and twiſt, corn, braſs-battery copper, copper wire, braſs-milting, &c. Connected with theſe were nearly forty veſſels, from thirty to fifty tons burthen each, to convey the ſeveral manufactures and the materials to and from Liverpool and other ſea-ports. Over the well is a beautiful polygonal building, ſupported by pillars and arches. The roof, ſays Mr. Pennant, is moſt exquiſitely carved in ſtone. Sculptured ornaments of groteſque animals, armorial inſignia, &c. are attached to different parts of the building. Some of the latter relate to the Stanley family, by one of whom it was probably erected, either in the reign of Henry VI., or Henry VII. An apartment over the well was a free chapel.

Of Holywell town, Mr. Bingley obſerves, that he knows of none in North Wales that, in a commercial view, is of more importance. The numerous manufactures in its vicinity, and its eaſy acceſs to the ſea, have rendered it the great mart of this part of the kingdom. The town is ſpacious, but irregular, pleaſantly ſituated on the ſlope of a mountain, which extends nearly to the water. Many of the houſes are good, and give to it an air of conſiderable opulence. At the baſe of the hill, near the well, is the pariſh-church, which was built in the year 1769, on the ſcite of a more ancient edifice. "It has only one bell," ſays Mr. Pennant, "and that not to be heard at any diſtance; ſo that the congregation is aſſembled by a walking-ſteeple, a man with a ſmall bell who ſounds the notice through the ſtreets." At a ſhort diſtance north of the town, in a narrow, retired vale, are ſome remains of Baſingwerk or Greenfield abbey. Of this building the walls, and ſome pillars of the refectory, are the chief remnants. The knights templars had an elegant chapel here. Veſtiges of Baſingwerk caſtle remain on an eminence near the monaſtic ruins; alſo, ſome mounds called Watt's dyke: this was a bold rampart of earth, which extended from Holywell to Oſweſtry in Shropſhire, and runs nearly parallel with the more noted Offa's dyke. Pennant's Hiſtory of Whiteford and Holywell, 4to. 1796, and Bingley's North Wales, two vols. 8vo. 1804.

HOLZAPFIL, a town of Germany, and capital of a county of the ſame name, ſituated on the borders of the Lahn, erected into a principality of the empire by Ferdinand III. This town lies at the foot of a mountain, on which is the tower of an ancient caſtle, the original ſeat of the princes of Naſſau; 4 miles N.E. of Naſſau. N. lat. 50 20'. E. long. 7 52'.

HOLZKIRCHEN, a town of Germany, in the county of Wertheim; 9 miles E. of Wertheim.

HOMA, a town of South America, in the government of Buenos-Ayres; 15 miles S. of Corrientes.

Homa, in *Surgery*, an anaſarcous or dropſical ſwelling.

HOMAGE, in its general ſenſe, denotes the reverence, reſpect, and ſubmiſſion, which a perſon yields his maſter, lord, prince, or other ſuperior.

The word is formed of the Latin *homo, man*; becauſe when the tenant takes his oath, he ſays, *Ego devenio homo veſter, I become your man*; for the ſame reaſon homage is called *manhood*; ſo the homage of his tenant and the manhood of his tenant are the ſame. Coke on Littl. fol. 64.

Homage, *Homagium*, *Hominium*, in *Law*, is an engagement or promiſe of fidelity; which the vaſſal, or tenant who holds a fee, renders to the lord, when admitted thereto.

In the original grants of lands and tenements, by way of fee, the lord did not only oblige his tenants to certain ſervices, but alſo took a ſubmiſſion, with promiſe and oath, to be true and loyal to him, as their lord and benefactor.

This ſubmiſſion, &c. is called homage; the form whereof, as appointed by ſtat. 17 Edward II. is in theſe words; When a free man ſhall do homage to his lord, of whom he holdeth in chief, he ſhall hold his hands together, between the hands of his lord, and ſhall ſay thus: "I become your man from this day forth, for my life, for member, and for worldly honour; and ſhall owe you my faith for the land I hold of you; ſaving the faith that I owe unto our ſovereign lord the king, and to mine other lords."

In this manner the lord of the fee, for which homage is due, takes homage of every tenant, as he comes to the land or fee. Glanvil, indeed, excepts ſome women; who only perform homage by their huſbands; becauſe homage is ſuppoſed to have a more immediate relation to ſervice in war: but Fitzherbert denies this exception. Nat. Brev. fol. 157.

It is added, that biſhops do no homage, but only fealty; and probably for the ſame reaſon as women. Yet do we read, that the archbiſhop of Canterbury does homage on his knees to our kings, at their coronation; and that the biſhop of Man was homager to the earl of Derby.

Fulbeck reconciles this: by our law, ſays he, a religious man may do homage, but may not ſay to the lord, *Ego devenio homo veſter*; becauſe he has already profeſſed himſelf to be only God's man; but he may ſay to him "I do unto you homage, and to you ſhall be faithful and loyal."

Homage and fealty, or faith, are two diſtinct things, and different duties. See Fealty.

Originally homage was performed by the gentlemen, and fealty by the peaſant. Others ſay, that homage was that performed to the lord himſelf, and fealty to his ſeneſchal, or ſteward, for his lord. It is added, that he who holds lands for term of life, owes homage, but not fealty.

Biſhops take the oath of fealty and loyalty to the king, for the temporalities they hold of him, or which are reſtored to them; and at the ſame time do homage to their ſovereign.

Homage *Fee*. See Fee.

Homage-*liege*, a more extenſive kind of homage, whereby the vaſſal held of the lord, not only for his land, but his perſon; ſo that the lord might uſe him againſt all mankind, whether within or without the kingdom; excepting againſt the king. See Liege.

This kind of homage was rendered bare-headed, with the hands joined on the Goſpels, and one knee on the ground, and without ſword, girdle, or ſpurs. By which it was diſtinguiſhed from frank homage. See Allegiance.

There are alſo other diſtinctions of homage; as,

Homage, *Plain*, or homage of a fee; where no oath of fidelity is taken.

Homage *of Devotion*, which is a donation made to the church; and does not import any duty, or ſervice at all.

Homage *of Peace*, which a perſon makes to another after a reconciliation, as an aſſurance that he will no longer diſturb his peace, &c.

Homage, *Simple*. See Allegiance.

Homage, again, is divided into *new*, or that performed upon the grant of the fee; and *aunceſtrel*.

Homage, *Aunceſtrel*, is where a man and his anceſtors, time out of mind, have held their land of the lord, and his anceſtors, by homage.

If ſuch lord have received homage, he is bound to acquit the tenant againſt all other lords above him, of every manner of ſervice; and if the tenant has done homage to his lord, and is impleaded, and vouches the lord to warranty, the lord is bound to warrant him; and if the tenant loſe, he ſhall recover in value againſt the lord ſo much of the lands as he had at the time of the voucher, or any time after.

Homage is alſo uſed for a jury, in a court-baron, becauſe commonly conſiſting of ſuch as pay homage to the lord of the fee. See Jury, Court-baron, and Manor.

Homage is alſo taken, in ſome caſes, for the particular place, or diſtrict, where the ſervices are to be performed.

HOMAGER, a perſon that does, or is bound to do, homage to another.

HOMAGIO Respectuando, a writ iſſued out to the eſcheator commanding him to deliver ſeiſin of lands to the heir that is of full age, notwithſtanding his homage not being done.

HOMAGIUM Reddere has been uſed to ſignify, to renounce homage: as where the tenant or vaſſal, made a ſolemn declaration of diſavowing his lord, for which there was a form preſcribed by the feudatory laws.

HOMALIUM, in *Botany*, is a genus ſo named by Jacquin, as he informs us, from ὁμαλης, *equality*, becauſe of the equal diſpoſition of the ſtamens. Jacq. Amer. 170. Schreb. 366. Willd. Sp. Pl. v. 2. 1225. Mart. Mill. Dict. v. 2. Swartz. Ind. Occ. v. 2. 988. Prodr. 86. Juſſ. 343. Lamarck Illuſtr. t. 483. (Racoubea; Aubl. Guian. v. 1. 589. t. 236.) Claſs and order, *Polyandria Trigynia*. Nat. Ord. *Roſaceæ*, or perhaps *Rhamni*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, divided into ſix or ſeven ovate-lanceolate, acute, widely-ſpreading ſegments. *Cor.* Petals ſix or ſeven, ovate, flat, a little longer than the calyx, ſpreading; nectary conſiſting of ſix or ſeven flat glands, which are alternate with the petals. *Stam.* Filaments varying from 18 to 28, awl-ſhaped, erect, the length of the corolla, three or four of them being inſerted into the receptacle, between the glands, within the baſe of each petal; anthers roundiſh, ſmall. *Piſt.* Germen roundiſh, hairy, immerſed in the baſe of the calyx; ſtyles three or more, erect; ſtigmas ſimple. *Peric.* Capſule woody, ovate, of one cell. *Seeds* numerous, ſmall.

Eſſ. Ch. Calyx ſix or ſeven-cleft. Corolla of ſix or ſeven petals. Stamens three in a bunch. Capſule of one cell, with many ſeeds.

Obſ. All the parts of the flower are permanent. This genus is ſuppoſed to be akin to *Blackwellia* of Commerſon and Juſſieu, (which is different from *Blackwellia* of Gærtner, t. 117), but the inſertion of the ſtamens is thought to diſtinguiſh them; ſee Willd. Sp. Pl. v. 2. 930. Lamarck. Illuſtr. t. 412. Juſſ. 343. We feel a ſtrong inclination to unite the two genera, but in deference to ſuch authorities ſhall now only ſpeak of undoubted ſpecies of *Homalium*.

1. *H. racemoſum.* Willd. n. 1. Jacq. Amer. 170. t. 183. f. 72. Swartz. Ind. Occ. v. 2. 989. Lamarck Illuſtr. t. 483. f. 2.—Leaves elliptical, with ſhallow ſerratures. Partial flower-ſtalks longer than the calyx. Petals ovate.—Native of banks of rivers in Martinique and Jamaica, flowering late in the autumn.—A lofty *tree*, with a tufted head, in habit like an elm. *Flowers* in bunches. *Stamens* 18 or 21, ſo that three are placed together within each petal. *Germen* ſurrounded by the calyx. *Seeds* browniſh.

2. *H. Racoubea.* Willd. n. 2. Swartz. Ind. Occ. v. 2. 991. Lamarck Illuſtr. t. 483. f. 1. (Racoubea guianenſis; Aubl. Guian. 590. t. 236.)—"Leaves elliptical, with broad ſerratures. Partial flower-ſtalks ſhorter than the calyx. Petals ovate.—A native of the woods of Guiana, flowering and bearing fruit in May.—*Stem* about four feet high, bearing tortuous *branches* ſix or eight feet long. *Leaves* alternate, ſmooth, ovate, obtuſely pointed. *Flowers* yellow. This ſpecies is very nearly allied to the laſt, but differs in having its leaves almoſt toothed and leathery, flowers larger, and fruit woody.

3. *H. anguſtifolium.* Sm. MSS. Leaves elliptic-lanceolate, ſlightly wavy. Partial flower-ſtalks very ſhort. Petals obovate.—Native of Sierra Leone, communicated by ſir Joſeph Banks in 1792.—The *leaves* are much ſmaller than in the laſt, narrower, and nearly entire. *Cluſters* axillary, ſimple, ſcarcely ſo long as the leaves. *Flowers* nearly ſeſſile, ſmaller than either of the preceding, and eſſentially diſtinguiſhed by the obovate ſhape of their petals.

HOMALOCENCHRUS. See Leersia.

HOMAN, or Oman, in *Geography*, a town of Fez, in the province of Habat, between Alcaçar-quiber, and Arzilla.

HOMBERG, William, in *Biography*, a celebrated phyſician and chemiſt, was born at Batavia, in the iſland of Java, in 1652. His father was a Saxon gentleman, who had entered into the ſervice of the Dutch Eaſt India company, and ultimately obtained the command of the arſenal of Batavia. He quitted that ſettlement however, and went to Amſterdam, where his ſon advanced rapidly in the courſe of his education, and became devoted to ſtudy. He went to Jena, Leipſic, and Magdeburg, where he purſued the ſtudy of the law, and was admitted to the bar in the laſt-mentioned place, in 1674. But without neglecting his profeſſion, he began to take great intereſt in the ſtudy of natural hiſtory; and becoming acquainted with Otto Guericke, who had invented the air-pump, and was purſuing experimental philoſophy with celebrity, he attached himſelf to this able man in order to be inſtructed in thoſe ſciences. His increaſing deſire for knowledge induced him to quit Magdeburg, and he ſet off to Italy, where he applied to the ſtudy of medicine, and particularly of anatomy and botany at Padua. When at Bologna, he diſcovered, by his experiments, the method of making the Bologna ſtone luminous, which had been almoſt loſt. At Rome he formed an intimate acquaintance with Marc Anthony Cœlio, a Roman nobleman, an able mathematician, aſtronomer, and mechaniſt, who was exceedingly dextrous in making large lenſes. Homberg applied ardently to theſe ſtudies, as well as to painting, ſculpture, and muſic, in which he made great progreſs. Leaving Italy, he travelled through France, and viſited England, where he laboured for ſome time with the celebrated Mr. Boyle. He then returned to Holland, and after improving himſelf in anatomy under De Graaf, rejoined his family, then reſiding at Quidlinburg. He had now decided on adopting the profeſſion of medicine, and took the degree of M.D. at Wittemberg; but he was ſtill more inclined to the purſuit of his favourite ſciences, than to ſettle in the practice of his profeſſion. Accordingly, he travelled to the north, in order to viſit Baldwin and Kunkel, the inventors of two ſorts of phoſphorus, which, at that time, made a conſiderable noiſe; and he obtained their methods of preparing it, in exchange for ſome other chemical ſecrets. He proceeded thence to the mines of Saxony, Hungary, Bohemia, and Sweden, in order to purſue his inquiries reſpecting the metals; and at Stockholm he laboured, together with M. Hierna, firſt phyſician to the king, in the laboratory recently eſtabliſhed there by his majeſty. He was ſtill urged by the love of liberty and ſcience to purſue his travels, notwithſtanding the wiſhes of his family that he ſhould ſettle in his own country, and he repeated his journey to Holland and France, where he was received by the ſcientific men with great favour. At the urgent requeſt of his father, who was now impatient at his delay, he had fixed the day of his departure from Paris, when M. Colbert, in the name of the king, made him ſuch advantageous offers, as induced him to remain in that metropolis. In 1682 he embraced the Catholic religion; but the next year he loſt his patron Colbert, and was diſinherited by his father for having changed his religion. In 1685 he was induced to pay a ſecond viſit to Rome, where he remained ſome years, practiſing medicine with great ſucceſs. On his return, his extenſive information, his phoſphorus, his microſcopes, an air-pump which he had invented, more perfect than thoſe of Guericke and Boyle, and various operations and diſcoveries, ſoon acquired for him a diſtinguiſhed rank among the moſt eminent philoſophers. In 1691 he was admitted a member of the Academy of Sciences, and through the favour of the abbé Bignon, director, he obtained the uninterrupted uſe of the laboratory of the academy. In 1702 the duke of Orleans ordered a magnificent laboratory, fitted up in the completeſt manner, to be put under the direction of Homberg, to whom he alſo aſſigned a penſion; and in 1704 the duke appointed him his firſt phyſician. Homberg married in 1708 the daughter of M. Dodart, an eminent phyſician, with whom he lived but a few years, being carried off by a dyſentery, to returns of which he had been for ſome time liable, in September 1715, at the age of ſixty-three. Homberg, although of a weak conſtitution, was exceedingly laborious. His acquirements were very extenſive; for beſides a thorough knowledge of every department of natural philoſophy and chemiſtry, he was well acquainted with hiſtory and languages. His mind was capable of a degree of attention, which enabled him to make obſervations, that might have eſcaped others; and his method of explaining them was ſimple, accurate, and conciſe. He never publiſhed any large work, but he furniſhed a great number of curious and intereſting memoirs to the Academy of Sciences, which were printed in their collections. Gen. Biog. Eloy. Dict. Hiſt.

Homberg, or *Homburg*, in *Geography*, a town of Germany, in the duchy of Berg; 24 miles E.S.E. of Cologne.—Alſo, a town of the principality of Heſſe Caſſel, ſituated on the Efze. It contains an iron-forge and a glaſs manufacture; 20 miles S. of Caſſel. N. lat. 51° 2′. E. long. 9° 20′.

Homburg *vor der Hohe*, or *Homburg in the mountains*, a town of Germany, which gives title to a branch of the houſe of Heſſe, called Heſſe-Homburg; ſeven miles N. of Frankfort on the Maine. N. lat. 50° 15′. E. long. 8° 32′.

Homberg *an der Ohm*, a town of Upper Heſſe, on the Ohm, with a caſtle on an eminence; 11 miles S.E. of Marpurg. N. lat. 50° 43′. E. long. 9° 1′.

Homberg, or *Homrig*, a town of Wurzburg; 14 miles W. of Wertheim.

Homburg, or *Hombourg*, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the diſtrict of Deux-Ponts; five miles N.N.W. of Deux-Ponts. N. lat. 49° 11′. E. long. 7° 21′. The place contains 1761, and the canton 4581 inhabitants, in 14 communes.

Homburg, or *Hockenburg*, a town of the duchy of Wurzburg, ſituated on the Maine; 15 miles W.S.W. of Wurzburg.

HOME, Henry, *Lord* Kames, in *Biography*, eminent as a judge and writer, was born in the county of Berwick in 1696. He was educated at home till he was of a proper age to be ſent to the univerſity of Edinburgh, to ſtudy the law as his future profeſſion. The acuteneſs of his genius, and the ſucceſs with which he applied himſelf to profeſſional ſtudies, were diſplayed by a number of publications on the civil and Scotch law. The firſt of theſe, publiſhed in 1728, conſiſted of “Remarkable Deciſions of the Court of Seſſions,” which he afterwards publiſhed, much enlarged, in the form of a dictionary in two volumes folio. Without enumerating all his works on legal ſubjects, we may mention, as the moſt curious of his productions in this claſs, “Hiſtorical Law Tracts,” containing fourteen ſeparate treatiſes upon intereſting ſubjects connected with the judicial and conſtitutional hiſtory of the country. He gave a multitude of proofs of indefatigable induſtry, and profound knowledge, which raiſed him to the firſt rank in his profeſſion, and in 1752 he was advanced to the bench of judges of the court of ſeſſion, on which promotion he took, according to the cuſtom of Scotland, the title of lord Kames, and his authority as a law writer is ſtill quoted at the Scotch bar, with the ſame reſpect as is paid to the luminaries of law in the Engliſh courts. We are now to conſider lord Kames in the character of a literary man; from his earlieſt days he had a decided turn for metaphyſical diſcuſſions, and maintained a correſpondence on theſe ſubjects with biſhops Berkeley and Butler, Dr. Clarke, and other great men who have become illuſtrious, by their talents, in the annals of their country. In 1752 he publiſhed “Eſſays on the Principles of Morality and Natural Religion.” In this work he endeavoured to eſtabliſh ſeveral general principles of action. He alſo openly avowed the doctrine of philoſophical neceſſity, which had become obnoxious by being adopted by ſome writers who rejected revealed religion; and though he cloſely allied it with the duties of morality and real religion, he underwent many attacks on its account. In 1761 he publiſhed for young perſons his “Introduction to the Art of Thinking,” which conſiſts of maxims and general obſervations on human nature and the conduct of life illuſtrated by examples. His great work, the “Elements of Criticiſm,” was given to the world in the year 1762, which is a truly original performance, and which diſcarding all arbitrary rules of literary compoſition derived from authority, eſtabliſhes a new theory upon the principles of human nature. In 1773 he appeared again before the public in his “Sketches of the Hiſtory of Man,” in two volumes 4to. This work compriſes many ſubjects of the greateſt importance relative to human ſociety. They are not all treated with equal accuracy, and ſome of the examples are taken from ſuſpected ſources. He publiſhed, in 1777, “The Gentleman Farmer, being an attempt to improve Agriculture by ſubjecting it to the Teſt of rational Principles.” This work was the reſult of much obſervation and practical knowedge of the buſineſs of farming, which he acquired by the purſuit on a large ſcale, on his own eſtate, in Perthſhire. In 1781 he publiſhed another work, entitled " Looſe Hints upon Education, chiefly concerning the Culture of the Heart," and in the following year he died at the age of eighty-ſix. Lord Kames was as much diſtinguiſhed by his vivacity in converſation, as the extent of his legal knowledge and literary labours. To a very advanced age he was the life and ſoul of all the parties with which he mixed: no topic could be ſtarted above or below his powers of diſcuſſion. Lord Kames was in the habit of riſing very early, and he was a man of great regularity and order in the diſpoſition of the ſeveral parts of his time: he ſeemed to know the value of each minute as it paſſed, and it was thus he roſe to the high eminence which he poſſeſſed, in oppoſition to all the obſtacles which the tumult of public buſineſs could throw in his way. In the friendſhips which he formed he was ardent, zealous, and ſincere. He attained to conſtant habits of devotion, and a perpetual ſenſe of the Deity, and a veneration for an over-ruling Providence ever dwelt upon his mind. From this ſource aroſe that propenſity, which appears in all his writings, of inveſtigating final cauſes, and tracing the wiſdom of the Supreme Author of nature. A few days before his death he went to the court of ſeſſion, addreſſed all the judges ſeparately, told them he was ſpeedily to depart, and took a ſolemn and affectionate farewel.

Home, in *Sea Language*, denotes either the ſituation of ſome object, where it retains its full force of action; or where it is properly lodged for convenience or ſecurity. In the former ſenſe it is applied to the ſails, and ſignifies, that their clues or lower corners are cloſe to the blocks upon the yard-arm, immediately beneath them: hence to haul home the top-ſail-ſheets, is to extend the bottom of the top-ſail to the lower-yard, by means of the ſheets. In the latter ſenſe, it uſually refers to the ſtowage of the hold; as a caſk, &c. is ſaid to be *home*, when it bears againſt and lies cloſe to ſome other objects: or to the anchor, which is ſaid to come home, when it looſens from the ground, by the effort of the cable, and approaches the place where the ſhip floated, at the length of her moorings.

Home *Breeds*, in *Rural Economy*, a term ſignifying ſuch breeds of cattle or other ſorts of live-ſtock, as are bred and reared in the particular diſtrict or county.

Home-*Diſtrict, the*, in *Geography*, a diſtrict of Naſſau, in the province of Quebec, Upper Canada, ſo conſtituted by a proclamation of lord Dorcheſter, in July 1788, and deriving its preſent name from an act of the provincial legiſlature. It is bounded E. by a meridian paſſing through the mouth of the river Trent; N. by the Ottawa river, into lake Tomigcanning and the bounds of the Hudſon's bay company, and alſo by part of lake Huron; W. by a meridian paſſing through the eaſtern extremity of Long point, or the N. Foreland; and S. by part of lake Ontario, and part of lake Erie.

Home, *Harveſt*. See Harvest.

Home-*ſtall*, in *Rural Economy*, a term frequently applied to the ſcite or ſituation of the farm-houſe, and other buildings including the farm-yard. It cannot be diſputed that farms are of greater or leſs value in proportion to the conveniencies which they poſſeſs, and the facility of the means of occupying them. It is well known that arable farms require an extent of buildings and other conveniencies adequate to the ſizes and particular kinds of them. Tenants are not unfrequently ſeen much checked and confined in their operations and improvements, as well as ſubjected to great waſte of produce, in conſequence of the want of a ſufficient extent of farm offices. But on the contrary, it is occaſionally to be noticed, that there is a prodigality of this ſort of buildings, which incurs vaſt unneceſſary expence, not only at firſt, but afterwards in the repairs that become requiſite. The extent of buildings ſhould conſequently be well proportioned to that of the farm, and rarely extended much beyond it. All extremes muſt be moſt carefully avoided. See Farm, and Farm-Yard.

Home-*ſtead*, the name of the ſituation or ſpace of ground on which the farm-houſe, buildings, and offices are raiſed. The ſituations intended for this purpoſe ſhould be choſen with much care and circumſpection, regard being conſtantly had to convenience, water, and various other points of importance. See Farm-Yard, and Home-*ſtall*.

HOMER, in *Biography*, juſtly celebrated as the prince of poets, flouriſhed, according to Blair, about 900 years before the Chriſtian era, though Prieſtley and others place this event half a century later. Seven cities diſputed the glory of having given him birth, *viz.* Smyrna, Rhodes, Colophon, Salamis, Chios, Argos, and Athens, but the probability is, that he was born either on the continent of Leſſer Aſia, or upon one of the iſlands near it. We have nothing certain reſpecting the life of this poet: critics have uſually thrown aſide as ſpurious and fabulous the life of Homer, ſaid to have been written by Herodotus. The detail of circumſtances contained in that piece is ſo circumſtantial and minute, that it can deſerve no credit whatever. There ſeems no doubt that, notwithſtanding the high reputation and vaſt celebrity which he has enjoyed for nearly three thouſand years, he ſpent his life in poverty, wandering about from city to city, and from the court of one prince to that of another, obtaining temporary patronage from the recital of his poems. If he were blind he probably became ſo in his old age. The origin and compoſition of the poems attributed to Homer, are involved in as much obſcurity, as the facts relating to his birth-place and life. In his celebrated poems entitled the Iliad and Odyſſey, the poet has diſplayed the moſt conſummate knowledge of human nature, and rendered himſelf immortal by the ſublimity, the fire, the ſweetneſs, and elegance of his poetry. In his Iliad, Homer has deſcribed the reſentment of Achilles, and its fatal conſequences in the Grecian army before the walls of Troy. In the Odyſſey, the poet has for his ſubject the return of Ulyſſes into his country, with the many misfortunes which attended his voyage after the fall of that city. Theſe poems are each divided into 24 books, the ſame number as there are letters in the Greek alphabet, and, though the Iliad claims an unconteſted ſuperiority over the Odyſſey, yet the ſame force, the ſame ſublimity and elegance prevail, though diveſted of its more powerful fire: and the great author of the " Sublime," compares the Iliad to the mid-day, and the Odyſſey to the ſetting-ſun, and adds that the latter ſtill preſerves its original ſpendour and majeſty, though deprived of its meridian heat. " Whether theſe were epic poems in the ſenſe now attached to the word, primarily formed upon a determinate plan, and conſtituting a whole;—whether they were a fortuitous aſſemblage of detached parts, connected by ſome later hand, by means of an aſſumed ſubject, or, laſtly, whether theſe rhapſodies were the work of one author or of ſeveral, are queſtions which have exerciſed, and which ſtill continue to exerciſe, the ingenuity of critics. There is no doubt that the conſtituent parts of theſe poems long wandered ſeparately through the principal cities of Greece, and the whole of them are ſaid by Plutarch to have been brought from Aſia to Greece by Lycurgus, and their firſt arrangement, in the order we now have them, is aſcribed to Piſiſtratus. But whatever doubt theſe circumſtances might throw upon the original plan of their

their compoſition, it is contended that all the parts ſo manifeſtly conſpire to that general purpoſe which is propoſed in the exordium, that they muſt have flowed from uniform deſign. The difficulty of conceiving how ſuch long works could be accurately tranſmitted by memory through ages, previouſly to the uſe of writing, increaſes the intricacy of the queſtion ;" but in anſwer to this it has been obſerved, that the poetry of Homer was ſo univerſally admired, that, in ancient times, every man of learning could repeat with facility any paſſage in the Iliad and Odyſſey. Theſe poems, it appears, from the very earlieſt times, were conſulted as authorities for local claims, and controverſies were decided reſpecting boundaries and prerogatives, by lines from the catalogue of Homer's ſhips. Modern travellers have been aſtoniſhed to behold the different ſcenes which the poems of Homer deſcribed 3000 years before, ſtill exiſting in the ſame unvaried form, and the navigator, who ſteers his courſe along the Ægean ſea, finds all the promontories and rocks which appeared to Neſtor and Menelaus, when they returned victorious from the Trojan war. By the ancients Homer was venerated and worſhipped as a god. The inhabitants of Chios celebrated feſtivals in his honour every fifth year: and the people of Cos conſidered it as their greateſt glory that the poet of Greece was buried in their iſland. Alexander was ſo much attached to the works of Homer, that he uſually placed them under his pillow, with his ſword, and he depoſited the Iliad in one of the richeſt and moſt valuable caſkets of Darius, obſerving, that the moſt perfect work of human genius ought to be preſerved in a box the moſt valuable and precious in the world. The beſt editions of the Iliad and Odyſſey are that by Dr. Barnes with the Greek ſcholia, in two volumes 4to. : that by Dr. Clarke publiſhed in 4to. 1729, and that by the learned Heyne. The moſt elaborate commentary is that by Euſtathius, biſhop of Theſſalonica, and the beſt Engliſh tranſlation is that by Pope: though Cowper's, in blank verſe, is thought to come nearer to the original.

HOMER, in *Geography*, a military townſhip of America, in Onondago county, New York, on the head-waters of the N. W. branch of Chenengo river; containing 612 inhabitants.

HOMER, *Omer*, or *Chomer*, a Jewiſh meaſure, containing the tenth part of the epha. See CORUS and MEASURE.

HOMESOKEN, or rather HAMSOKEN; ſometimes alſo written *Hamſoka*, and *Hamſolna*, the privilege or protection which every man enjoys in his own houſe.

" Hamſokne, hoc eſt quietus eſſe de amercimentis pro ingreſſu hoſpitii violenter et ſine licentia contra pacem regis, et quod teneatis placita de hujuſmodi tranſgreſſione in curia veſtra." W. Thorn. 2030.

Hence, he who invades that freedom, is properly ſaid, *frangere homſocnam*.

This crime ſeems to amount to what we now call burglary; which is a crime of a heinous nature, as being not only a breach of the king's peace, but a breach of that liberty which a man hath in his own houſe, which, as we commonly ſay, ſhould be his caſtle, and therefore ought not to be invaded. Bracton. lib. iii.

HOMFELDS, in *Geography*, a town of Germany, in the county of Lippe; 9 miles E. of Lemgow.

HOMICIDE, of *homo, a man*, and *cædo, I kill*, in *Common Law*, the killing of a man.

Homicide is divided into three kinds: *viz. juſtifiable, excuſable*, and *felonious*. The firſt has no guilt at all; the ſecond very little; but the third is the higheſt crime againſt the law of nature, which man is capable of committing.

Juſtifiable homicide is ſuch as is owing to ſome unavoidable *neceſſity*, without any intention or negligence in the perſon that kills, and, therefore, without any ſhadow of blame. Of this kind is the act of a magiſtrate or officer, who puts a malefactor to death, in obedience to the law, and in the execution of public juſtice. Homicide is alſo *juſtifiable* for the advancement of public juſtice; as, where an officer, in the execution of his office, either in a civil or criminal caſe, kills a perſon that aſſaults or reſiſts him (1 Hal. P.C. 494. 1 Hawk. P.C. 71.); where an officer, or any private perſon, attempts to take a man charged with felony, but is reſiſted, and in the endeavour to take him, kills him (1 Hal. P. C. 494.); where officers, in caſe of a riot or rebellious aſſembly, endeavouring to diſperſe the mob, kill them; ſuch officers are juſtified both by common law (1 Hal. P. C. 495. 1 Hawk. P. C. 161.), and by the riot act, 1 Geo. I. cap. 5. Where priſoners are killed by the gaoler or officer, in endeavouring to prevent their eſcape (1 Hal. P. C. 496.); where treſpaſſers in foreſts, parks, chaſes, or warrens, refuſe to ſurrender to the keepers, they may be ſlain; (21 Edw. I. ſtat. 2. 3 & 4 W. & M. cap. 10.) But in all theſe caſes there muſt be an apparent neceſſity; ſo that the party could not be arreſted or apprehended, the riot could not be ſuppreſſed, the priſoners could not be kept in hold, the deer-ſtealers could not but eſcape, unleſs ſuch homicide were committed, without which this kind of homicide is not juſtifiable. When one champion killed another in battle, ſuch homicide was juſtifiable, and was imputed to the juſt judgment of God (1 Hawk. P. C. 71.) Moreover, ſuch homicide, as is committed for preventing any forcible and atrocious crime, is juſtifiable by the law of nature, and by the law of England. (24 Hen. VIII. cap. 5.) Thus, if any perſon attempts a robbery or murder, or endeavours to break open a houſe in the *night-time*, or to burn it (1 Hal. P. C. 488.), and ſhould be killed in the attempt, the ſlayer ſhall be acquitted and diſcharged. This is agreeable to the Jewiſh law, Exod. xxii. 2. to the laws of Athens, and the Roman law of the Twelve Tables. The Engliſh law alſo juſtifies homicide in defence of *chaſtity*; which ſee.

Excuſable homicide is ſuch as the law excuſes from the guilt of felony, though it implies ſome degree of fault and blame. This is either *per infortunium, i. e.* by miſadventure, or *ſe defendendo*, upon a principle of ſelf-preſervation in a ſudden affray. See CHANCE-*medley*.

The firſt is, where a man doing a lawful act, without any intention of hurt, unfortunately kills another; as where a man has a hatchet at work, the head of which flies off, and kills a ſtander-by, or where a perſon, qualified to keep a gun, is ſhooting at a mark, and undeſignedly kills a man (1 Hawk. P. C. 73, 74). Thus alſo, when a parent is moderately correcting his child, a maſter his apprentice or ſcholar, or an officer puniſhing a criminal, and happens to occaſion his death, it is only miſadventure; but if he exceeds the bounds of moderation, in the manner, the inſtrument, or degree of puniſhment, and death enſues, it is at leaſt manſlaughter, and in ſome caſes, according to circumſtances, murder.

Theſe two ſpecies of *excuſable* homicide are ſimilar in their blame and puniſhment. Among the Jews, the ſlaughter even of enemies required a ſolemn purgation, which implies that the death of a man, however it happens, will leave ſome ſtain behind it. And the Moſaical law (Numb. c. 35. and Deut. c. 10.) appointed certain cities of refuge for him who killed his neighbour unawares, &c. But he was not held wholly blameleſs, any more than in the Engliſh law; ſince the avenger of blood might ſlay him before he reached his aſylum, or if he afterwards ſtirred out of it till the death of the high-prieſt. In the imperial law likewiſe caſual homicide was excuſed, by the indulgence of the emperor, ſigned with his own ſign manual, "adnotatione principis:" otherwiſe the death of a man, however committed, was in ſome degree puniſhable. Among the Greeks homicide by misfortune was expiated by voluntary baniſhment for a year. (Plato de leg. l. ix.) In Saxony a fine is paid to the kindred of the ſlain: which alſo, among the weſtern Goths, was little inferior to that of voluntary homicide (Stiern. de jure Goth. l. iii. c. 4.): and in France no perſon was ever abſolved in caſes of this nature, without a largeſs to the poor, and the charge of certain maſſes for the ſoul of the party killed. By our laws theſe two ſpecies of homicide formerly incurred a forfeiture, as ſome ſay, of all the goods and chattels; according to others, only of part of them, by way of fine or *weregild,* which was probably diſpoſed of, as in France, *in pios uſus,* or for the benefit of his ſoul. But the delinquent has now a pardon, and writ of reſtitution of his goods, as a matter of courſe and right, only paying for ſuing out the ſame (2 Hawk. P. C. 381.); and in moſt caſes the judge will grant a general verdict of acquittal. Foſt. 289.

Felonious homicide is the act of killing a human creature without juſtification or excuſe. This is either ſelf-murder (ſee Felo *de ſe*); or the killing of another man, which is divided into *manſlaughter* and *murder;* which ſee reſpectively. Blackſt. Com. book iv. cap. 14.

HOMILY, Ὁμιλια, formed of ὁμιλος, *aſſembly,* originally ſignifies a conference, or converſation; but the word has ſince been applied to an exhortation, or ſermon, delivered to the people.

The Greek *homilia,* ſays M. Fleury, ſignifies a familiar diſcourſe, like the Latin *ſermo;* and diſcourſes delivered in the church took theſe denominations, to intimate, that they were not harangues, or matters of oſtentation and flouriſh, like thoſe of profane orators, but familiar and uſeful diſcourſes, as of a maſter to his diſciples, or a father to his children.

All the homilies of the Greek and Latin fathers are compoſed by biſhops. We have none of Tertullian, Clemens Alexandrinus, and many other learned perſons; becauſe, in the firſt ages, none but biſhops were admitted to preach.

The privilege was not ordinarily allowed to prieſts, till toward the fifth century. St. Chryſoſtom was the firſt preſbyter that preached ſtatedly. Origen and St. Auguſtine alſo preached, but it was by a peculiar licence, or privilege.

Photius diſtinguiſhes homily from ſermon; in that the homily was performed in a more familiar manner; the prelate interrogating and talking to the people, and they, in their turn, anſwering and interrogating him; ſo that it was properly a converſation; whereas the ſermon was delivered with more form, and in the pulpit, after the manner of the orators.

There are ſeveral fine homilies of the fathers ſtill extant; and, particularly, of St. Chryſoſtom, St. Gregory, &c. The practice of compiling homilies, which were to be committed to memory, and recited by ignorant or indolent prieſts, commenced towards the cloſe of the eighth century; when Charlemagne ordered Paul Deacon and Alcuin to form homilies or diſcourſes upon the Goſpels and Epiſtles, from the ancient doctors of the church. This gave riſe to that famous collection, entitled the Homiliarium of Charlemagne, and which being followed as a model by many productions of the ſame kind, compoſed by private perſons, from a principle of pious zeal, contributed much (ſays Moſheim,) to nouriſh the indolence, and to perpetuate the ignorance of a worthleſs clergy. Eccleſ. Hiſt. vol. ii. p. 254. 8vo. ed.

At the time of the Reformation there were ſeveral of theſe homilies compoſed and printed, and ordered to be read in ſuch churches as were not provided with a ſufficiently learned miniſter, in order to prevent unſound doctrine being taught in remote country places. The homilies of the eſtabliſhed church of England are contained in two books; the former of which was publiſhed in the reign of Edward VI., and the latter in the beginning of the reign of queen Elizabeth. Both theſe are pronounced by the 35th article of the church to "contain a godly and wholeſome doctrine, and neceſſary for theſe times," *i. e.* for the times in which they were publiſhed. The authors of theſe homilies were the great reformers Cranmer, Ridley, Latimer, and Jewel. Biſhop Tomline mentions, in his "Refutation of Calviniſm, 8vo. 1811, that not one of the peculiar doctrines of Calvin is mentioned in either of theſe two books: the word Predeſtination does not occur from the beginning to the end of the homilies; the word Election occurs upon one occaſion only, and then it is uſed in its true ſcriptural ſignification, very different from that in which it is uſed by Calviniſts: the word Reprobation does not occur at all: nothing is ſaid of abſolute decrees, partial redemption, perſeverance, or irreſiſtible grace.

HOMILIES, Clementine. See Clementina.

HOMINE *capto in withernam,* in *Law,* a writ for apprehending him that has taken any bondman or woman, and led him or her out of the country; ſo that he or ſhe cannot be replevied according to law. See Withernam.

Homine *eligendo ad cuſtodiendam peciam ſigilli pro mercatoribus editi,* a writ directed to a corporation for the choice of a new perſon to keep one part of the ſeal appointed for ſtatutes merchant, when a former is dead according to the ſtatute of Acton Burnel.

Homine *replegiando,* a writ for the bailing of a man out of priſon, when he is confined without commandment of the king or his judges, or for any cauſe that is repleviable. But this writ is now ſeldom uſed; a writ of habeas corpus being ſued out on the neceſſary occaſions.

HOMINICOLÆ, formed of the Latin *homo, hominis, man,* and *colo, I worſhip,* in *Antiquity,* a name which the Apollinarians gave to the orthodox, to denote them worſhippers of man.

As the orthodox maintained that Jeſus Chriſt was God-man, the Apollinarians accuſed them of adoring a man, and therefore called them *hominicolæ.*

HOMMACKS, in *Enginery,* are uſed by Mr. Smeaton to denote ſand hills thrown up by the tide; ſometimes alſo they are called paddocks.

HOMMEDAL, in *Geography,* a town of Norway, in the dioceſe of Chriſtianſand; 19 miles N.N.E. of Chriſtianſand.

HOMMOC, in *Sea Language,* ſignifies a hillock, or ſmall eminence of land reſembling the figure of a cone, and appearing on the ſea-coaſt of any country.

HOMNONA, in *Geography,* a town of Hungary; 14 miles N.E. of Matusfalva.

HOMO, Man, in *Zoology.* See Man.

HOMOCENTRIC, compoſed of ὁμος, *ſimilar,* and κεντρον, *centre,* in *Aſtronomy,* a term of the ſame import with concentric.

HOMOCHROA, in *Natural Hiſtory,* the name of a genus of pebbles.

The word is derived from the Greek ὁμος, *ſimilar,* and χρωα, *colour,* and expreſſes ſuch pebbles as are not veined, but all of one ſimple and ſimilar colour. Theſe are bodies compoſed of cryſtalline matter, conſiderably debaſed by earth, and this of various kinds in the different ſpecies, but only of one kind in the ſame ſpecies, which is thence always of one colour, and not ſubject to veins. Of this genus there are only five known ſpecies; the white, red, yellow, blueiſh, and greeniſh. All theſe are covered with external coats or cruſts, like thoſe of the common pebble. Hill's Hiſt. of Foſſ. p. 510.

HOMODROMUS Vectis, in *Mechanics*, a lever, in which the weight is in the middle between the power and fulcrum, or the power in the middle between the weight and fulcrum. See Lever.

The word homodromus is derived from ὁμος, *ſame*, and δρομος, *courſe*, becauſe in this ſpecies of lever the weight and power move in the ſame direction; as in the heterodromus they move in contrary directions.

HOMOEOTELEUTON, Ὁμοιοτελευτον, a figure in *Rhetoric*, whereby ſeveral verbs in a ſentence are made to end alike; as, eos deduci, evehi quam deferi malui: or, ut vivis invidioſe, delinquis ſtudioſe, loqueris odioſe.

HOMOGENEOUS, or Homogeneal, compoſed of the Greek ὁμος, *like*, and γενος, *kind*, is a term applied to various ſubjects, to denote that they conſiſt of ſimilar parts, or of parts of the ſame nature and kind; in contradiſtinction to heterogeneous, where the parts are of different natures, &c.

Natural bodies are generally compoſed of homogeneous parts, as a diamond, a metal, &c. Artificial bodies, on the contrary, are aſſemblages of heterogeneous parts, or parts of different qualities; as a building of ſtone, wood, &c.

HOMOGENEAL Light, is that whoſe rays are all of one and the ſame colour, degree of refrangibility, and reflexibility. See Light.

Homogeneal *Numbers* and *Plants*, are thoſe of the ſame kind and nature.

Homogeneal *Surds*, are ſuch as have one common radical ſign; as $\sqrt[3]{27}$, and $\sqrt[3]{3}$. See Surd.

HOMOGENEUM Comparationis, in *Algebra*, the known quantity in an equation; called alſo *abſolute number*.

It is called *homogeneum comparationis*, of *compariſon*, to diſtinguiſh it from the other terms; which, though homogeneous as well as this, *i. e.* always raiſed to the ſame degree of power, are not the quantities of which things are here compared or referred.

HOMOGRAMMI, Ὁμογραμμι, among the ancients, an appellation given to the athletæ who drew the ſame letter, and on that account were to engage together; for when any number of athletæ were to enter the liſts, in order to determine with whom every one ſhould contend, they threw into an urn a number of letters equal to that of the athletæ, but ſo that there were always two leters of a ſort, as two *a*'s, or two *b*'s. After theſe had been ſhaken together, the athletæ drew them out, and thoſe who got the ſame letter were to fight each other.

HOMOIOCATALECTON, Ὁμοιοκαταληκτον, in *Rhetoric*, a figure wherein the different parts of a ſentence have the ſame termination.

Homoiocatalecton is uſed as a genus to denote ſimilar terminations and words; and homoioptoton and homoioteleuton are made its ſpecies.

HOMOIOMERICAL Principles, of ὁμοιος, *ſimilar*, and μερη, *part*, a peculiar kind of principle, ſuppoſed by Anaxagoras in all mixed bodies; being determinate numbers of ſuch ſimilar principles, as, when they came to be parts, *e. gr.* of an animal body, would there make ſuch maſſes and combinations as their nature required; *viz.* the ſanguinary particles would then meet together, and make blood, the urinous particles conſtitute urine, the oſſeous ones bones, the carneous fleſh, &c. See Principle.

HOMOIOPTOTON, Ὁμοιοπτωτον, a figure in *Rhetoric*, whereby the ſeveral parts of a ſentence end with the ſame caſe, or tenſe of a like ſound; *e. gr. mœrentes, flentes, elachrymantes, & miſerantes.* Iſocrates is particularly celebrated for this figure. Some of the beſt orators have induſtriouſly avoided this figure, becauſe it has too much the appearance of art.

HOMOLINON, a word uſed by ſome authors to expreſs crude flax, and by others for a coarſe ſort of flaxen linen, made of the rough threads unwhitened, which was uſed by the ancients for towels to rub people after bathing.

HOMOLOGATION, in the *Civil Law*, the act of confirming or rendering a thing more valid and ſolemn, by publication, repetition, or recognition thereof.

The word comes from the Greek ὁμολογια, *conſent*, *aſſent*, formed of ὁμος, *ſimilis*, *like*, and λογος, of λεγειν, *dicere*, *to ſay*; *q. d. to ſay the ſame thing, to conſent, agree.*

HOMOLOGOUS, in *Geometry*, is applied to the correſpondent ſides of ſimilar figures, which are ſaid to be homologous, or in proportion to each other.

The word is compoſed of ὁμος, *ſimilar*, and λογος, *ratio*, *reaſon*; *q. d.* quantities *alike* to each other in ratio. So, if the ratio of A to B be the ſame as of C to D, here A is homologous to C, as B to D; becauſe of the ſimilitude between the antecedents and conſequents. The two antecedents, and the two conſequents, then, in any continued geometrical proportion, are homologous terms.

Thus, the baſe of one triangle is homologous to the baſe of another ſimilar triangle: ſo in ſimilar triangles, the ſides oppoſite to equal angles are ſaid to be homologous.

Equiangular, or ſimilar triangles, have their homologous ſides proportional.

All ſimilar triangles, rectangles, and polygons, are to each other as the ſquares of their homologous ſides.

Homologous *Things*, in *Logic*, are ſuch as agree in name, but are of different natures. Theſe coincide with what we otherwiſe call *equivocal* and *homonymous* terms.

HOMONOIA, in *Botany*, from ὁμονοια, *concord*, alluding to the union of the ſtamens into various tribes, all co-operating to one end. Lour. Cochinch. 636. Claſs and order, *Dioecia Polyadelphia.* Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of three ovate, concave, coloured leaves. *Cor.* none. *Stam.* Filaments about 200, equal to the calyx, united into 20 bundles; anthers roundiſh,

Female, on a ſeparate plant, *Cal.* Perianth of one leaf, many-cleft, acute, permanent. *Cor.* none. *Piſt.* Germen ſuperior, roundiſh; ſtyle none; ſtigmas three, oblong, villous. *Peric.* Capſule three-lobed, with three cells, and three valves. *Seeds* roundiſh, ſolitary.

Eſſ. Ch. Male, Calyx of three coloured leaves. Corolla none. Stamens 200, in 10 bundles.

Female, Calyx inferior, many-cleft. Corolla none. Stigmas three. Capſule of three cells. Seeds ſolitary.

1. H. *riparia.* A native of the banks of rivers in Cochinchina, where it is called *Rì rì bò foung.* It is a *tree*, ſix feet high, with a thick, upright ſtem, much branched. The *leaves* are linear, lanceolate, alternate, entire, downy. *Flowers* ſmall, in nearly terminal linear ſpikes, called by Loureiro *amenta*, or catkins; but as he deſcribes the male catkin with three ſcales to each flower, and a three-leaved perianth beſides, it is manifeſt the former muſt be bracteas. The whole of his deſcription beſides indicates one of the natural order of *Euphorbiæ*, which are not amentaceous plants.

HOMONOPAGIA, a word uſed by ſome medicinal authors for the head-ach.

HOMONYMIA, in *Logic*, an equivocation. See HOMONYMON, &c.

HOMONYMON, Ὁμωνυμον, compoſed of ὁμος, *ſimilis*, and the Ionic ονομα, for ονυμα, *name*, a word which has different meanings, or which is uſed to expreſs things of different nature and quality.

Homonyma are the ſame with what are otherwiſe called *polyſema*, *ſynonema*, and *equivocals*.

HOMOOUSANS, HOMOUSIANS, *Homouſianianiſts*, *Homouſiaſts*, formed of ὁμουσιος, or ὁμοουσιος, ſignifying *of the ſame ſubſtance*, are names which the Arians anciently gave to the orthodox, becauſe they held that God the Son is *homoouſios*, *i. e. con-ſubſtantial* with the Father. Hunneric, king of the Vandals, who was an Arian, publiſhed a reſcript, directed to all the Homoouſian biſhops. See PERSON, &c.

HOMOOUSIOS, Ὁμοουσιος, among *Divines*, a being of the ſame ſubſtance or eſſence with another.

The divinity of Chriſt having been denied by the Ebionites and Cerinthians in the firſt century, by the Theodotians in the ſecond, by the Artemonians at the beginning of the third, and by the Samoſatenians, or Paulians, towards the cloſe of the ſame, a council was aſſembled at Antioch in 269, wherein Paulus Samoſatenus, head of this laſt ſect, and biſhop of Antioch, was condemned and depoſed, and a decree publiſhed, as ſome have ſaid, wherein Chriſt is aſſerted to be God of God, and ὁμοουσιος, *i. e. conſubſtantial* with the Father.

It has been urged by ſeveral ancient writers of the fourth century, *viz.* Athanaſius, Hilary of Poictiers, and Baſil, that the council of Antioch rejected the word ὁμουσιος, or *conſubſtantial*, as improper: and if we conſider that Euſebius, who has been called an Arian, ſpeaks of Malchion, who directed and governed at this council, as a man of uncommon ſoundneſs in the faith of Chriſt, we may preſume that the term was not introduced in this council. The council of Nice, however, aſſembled in 325, expreſsly eſtabliſhed the Homoouſian doctrine. Many learned writers have taken pains to vindicate the orthodoxy of the council of Antioch, and to ſhew that both theſe councils held the ſame doctrine. See ARIANS.

HOMOPHAGI. See OMOPHAGI.

HOMOPHONI, in the *Ancient Greek Muſic*, implied uniſons, contraſted with *Antiphoni*, which meant ſymphonies, or muſic in octaves. The word is derived from ὁμος, *alike*, and φωνη, *ſound*.

HOMOPHONI, *Homophonous*, in *Greek Muſic*, was equivalent to *uniſons*, or uniſonous performance vocal or inſtrumental, in which the ſeveral parts were of the ſame pitch.

HOMORAN, or HOMRAN, in *Geography*, a town of Arabia, in the province of Yemen; between Sana and Beit-al-Fakih. In a hill in the vicinity of this town, there are ſaid to be 360 reſervoirs for water, cut in the rock. In its diſtrict is comprehended a large and fertile mountain, called Burra.

HOMORIUS, in *Mythology*, is an epithet given to Jupiter by the Greeks, anſwering to *Terminalis* among the Romans. Polyb. Hiſt. lib. ii.

HOMOROD, in *Geography*, a town of Tranſilvania; 15 miles N. of Fogaras.

HOMOTONOS, in *Medicine*, an epithet made the characteriſtic of a certain kind of fevers, which continue from the beginning to the end in one equable and uniform tenor, without exacerbation or relaxation.

HOMS, in *Geography*. See EMESA.

HOMUNCIONALES, in *Eccleſiaſtical Hiſtory*, an appellation given by the Arians to the orthodox, who ſaid there were two natures and ſubſtances in Chriſt.

HOMUNCIONISTS, HOMUNCIONISTÆ, formed of *homuncio*, a diminutive of *homo*, *a man*, q. d. *little man*, a ſect of heretics, the followers of Photinus, and from him alſo called Photinians.

They had this appellation, becauſe of their denying the two natures of Jeſus Chriſt, and holding that he was only mere man.

HOMUNCIONITES, HOMUNCIONITÆ, were a ſect of ancient heretics, whoſe diſtinguiſhed dogma it was, that the image of God was impreſſed on the body, not on the ſoul or mind of man.

HO-NAN, in *Geography*, a moſt delightful province of China, ſituated near the centre of the country, and called by the Chineſe Tong-hoa, or the Middle Flower. It is bounded on the N. by the provinces of Pe-tcheli and Chan-ſi, on the S. by Hou-quang, and on the E. by that of Chan-tong. Its capital is Cai-fong. The ancient emperors, invited by the mildneſs of the climate and the beauty of the country, fixed their reſidence here for ſome time. The abundance of its fruits, paſtures, and corn, the effeminacy or rather voluptuouſneſs of its inhabitants, and the cheapneſs of its proviſions, have prevented trade from flouriſhing in this, as it has done in other provinces of the empire. The whole country is flat, except towards the weſt, where ariſes a long chain of mountains, covered with thick foreſts; and the land is in ſuch high ſtate of cultivation, that thoſe who travel through it imagine they are walking in an immenſe garden. Beſides the river Hoang-ho, which traverſes this province, it is watered by a great number of ſprings and fountains; it has alſo a valuable lake, which invites to its banks a prodigious number of workmen, becauſe its water has the property of communicating to ſilk a luſtre, which cannot be imitated. Excluſively of forts, caſtles, and places of ſtrength, this province contains eight *fou*, or cities of the firſt claſs, and 102 of the ſecond and third. The population of this province, according to ſir George Staunton, amounts to 27,000,000 perſons.

HO-NAN, a city of the firſt claſs in the fore-mentioned province, ſituated amidſt mountains and between three rivers. The Chineſe formerly believed this city to be the centre of the earth, becauſe it was the middle of their empire. Its juriſdiction is very extenſive; for it comprehends one city of the ſecond claſs, and 13 of the third. One of theſe cities named Teng-fong-hien, is famous on account of the tower erected by the celebrated Tcheou-kong for an obſervatory; in it is to be ſtill ſeen an inſtrument which he made uſe of to find the ſhadow at noon, and to determine the latitude. This aſtronomer lived above 1000 years before the Chriſtian era, and the Chineſe pretend that he invented the mariner's compaſs. N. lat. 34° 44′. E. long. 112° 9′.

HONANELLA, a town of Hindooſtan, in Sanore, on the Tungebadra; 15 miles E. of Sanore.

HONCKENYA, in *Botany*, named by profeſſor Willdenow, in honour of his friend Gerard Auguſtus Honckeny, an able agriculturiſt. Willd. in Uſt. Delect. v. 2. 200. Sp. Pl. v. 2. 325.—Claſs and order, *Octandria Monogynia*. Nat. Ord. *Tiliaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five coriaceous, linear leaves, hairy and coloured externally, deciduous. *Cor.* Petals five, oblong, obtuſe, rather ſhorter than the calyx, deciduous. Nectaries very numerous, capillary, dilated at the top, reſembling ſtamens, ſhorter than the petals, inſerted into the receptacle. *Stam.* Filaments eight, rather longer than the nectaries, inſerted into the receptacle, compreſſed, linear, ſlightly dilated at their baſe; anthers erect, oblong, of two cells. *Piſt.* Germen ſuperior, oblong, hiſpid; ſtyle thick, cylindrical, ſhorter than the ſtamens, erect; ſtigma with ſix teeth. *Peric.* Capſule oblong, clothed with very long thorns, of five cells and five valves, whoſe edges form the partitions. *Seeds* numerous, roundiſh, rather compreſſed, brown, rough with elevated points, half clothed with a thin membranous tunic, and affixed to the central column.

Eſſ. Ch. Calyx of five leaves, inferior. Petals five. Nectaries numerous, reſembling ſtamens. Capſule thorny, with five cells and five valves. Seeds numerous, each with a membranous tunic.

1. H. *ficifolia.* Willd. in Uſt. Delect. v. 2. 201. t. 4. Native of Guinea, where it was gathered by Mr. Iſert. *Stem* woody; its branches round, clothed with ſhort brown pubeſcence. *Leaves* alternate, on ſhort ſtalks, toothed, or rather ſharply ſerrated, two or three inches long; tawny and downy beneath: the upper ones oblong, obtuſe, undivided; the lower palmate, with three or five blunt lobes. *Flowers* terminal, ternate, ſtalked, above an inch wide, of a blueiſh purple.—Nearly akin to *Aubletia* of Schreber and Willdenow, as the latter obſerves, but "diſtinguiſhed by the form of its capſule, the ſtamen-like nectaries, and the tunicated ſeeds."—The latter is indeed a good mark, but the ſuppoſed nectaries are probably only barren ſtamens.

HOND, in *Geography*, a town of Hungary, 10 miles N.W. of Tokay.

HONDA, a town of America, in New Granada, ſituated on the river Magdalena, in N. lat. 5° 16', and long. E. of Quito 4 9'. M. Bouguer repreſents it as a pleaſant little town, and the chief mart of the commerce between Quito and the northern provinces.

Honda, a bay on the N. coaſt of the iſland of Cuba; 70 miles W. of Havannah. N. lat. 22° 58'. W. long. 83° 25'.—Alſo, a bay on the E. coaſt of the province of Honduras, northward of Cape Gracias á Dios.—Alſo, a bay on the coaſt of South America, in the province of St. Martha. N. lat. 12°. W. long. 71° 6'.

HONDEKOETER, Gilles, in *Biography*, born at Utrecht in 1583, imitated the ſtyle of compoſition, and the manner of colouring, of Roland Savery, and David Vinckenbooms. He ſtudied after nature thoſe views which he intended for his landſcapes, and in general made an agreeable choice. The forms and leafing of his trees are more in the taſte of Vinckenbooms than Savery; but they are well handled, and firmly pencilled, though ſometimes perhaps they are a little too brown, or too yellow.

He painted different kinds of fowls with ſingular truth and exactneſs, and frequently filled his ſmall landſcapes with no other objects; but thoſe he finiſhed highly, and with great tranſparence of colouring.

Hondekoeter, Gysbrecht, born at Utrecht in 1613, was ſon of the preceding, from whom he learned deſign and colouring. The ſubjects he painted were, cocks, hens, ducks, and other domeſtic fowls, which he deſcribed in a lively and ſtrong manner, giving his objects agreeable attitudes, and colouring them exactly after nature. The works of this maſter are very often injudiciouſly aſcribed to his ſon, although the paintings of Gyſbrecht are in every reſpect abundantly inferior to thoſe of Melchier Hondekoeter.

Hondekoeter, Melchier, ſon of the preceding, was born at Utrecht in 1636, and from his infancy was carefully trained up to the profeſſion by his father. He choſe the ſame ſubjects; but, in his manner of painting them, he ſurpaſſed not only his maſter, but even the beſt of his contemporaries, in a very high degree. Till he was ſeventeen years of age he practiſed under the direction of Gyſbrecht and accuſtomed himſelf to paint ſeveral ſorts of birds; but he was particularly pleaſed to repreſent cocks, hens, ducks chickens, and peacocks, which he deſcribed in an elegant variety of actions and attitudes.

After the death of his father, which happened in 1653, he received ſome inſtructions from his uncle John Baptiſt Weeninx; but his principal and beſt inſtructor was nature, which he ſtudied with intenſe application, and that enabled him to give to every animal he painted ſuch truth, ſuch a degree of force, expreſſion, and life, as ſeemed to equal nature itſelf; nor did any artiſt take more pains to ſtudy every point that might conduce to the perfection of his art. His pencil was wonderfully neat and delicate; his touch light, his colouring exceedingly natural, lively, and remarkably tranſparent; and the feathers of his fowls were expreſſed with ſuch a ſwelling ſoftneſs, as might readily and agreeably deceive the eye of any ſpectator.

It is reported, that he had trained up a cock to ſtand in any attitude he wanted to deſcribe, and that it was his cuſtom to place that creature near his eaſel; ſo that, at the motion of his hand, the bird would fix itſelf in the proper poſture, and would continue in that particular poſition, without the ſmalleſt perceptible alteration, for ſeveral hours at a time.

The landſcapes which he introduces as the back grounds of his pictures, are adapted with peculiar judgment and ſkill, and admirably finiſhed; they harmonize with his ſubject, and always increaſe the force and the beauty of his principal objects. His touch was very ſingular in imitating the natural plumage of the fowls he painted; which not only produced a charming effect, but alſo may prove ſerviceable to an intelligent obſerver, to aſſiſt him in determining which are the genuine pictures of this maſter, and which are impoſitions. The works of Hondekoeter are juſtly in very great requeſt and eſtimation, and they generally afford a large price, almoſt in proportion to their value. He died 1695, aged 59.

HOND-HABEND. See Hand-Habend.

HONDIUS, Abraham, in *Biography*. This painter, who is well known in our kingdoms, was born at Rotterdam in 1638, according to the moſt authentic writers, though Deſcamps fixes his birth in 1650, twelve years later. He appears to have been an univerſal maſter, painting, with equal readineſs, landſcapes, animals of all kinds, particularly dogs, huntings of wild animals, boars, deer, wolves, and foxes, as alſo converſations and fowls; but his favourite ſubjects were huntings.

His manner ſeems peculiar to himſelf; it was bold and free; and, except Rubens and Snyders, few maſters have painted animals in a greater ſtyle, or with more ſpirit. There is certainly a great deal of fire in his compoſitions; but his colouring is often extravagant, and his drawing extremely incorrect. In general his pencilling was harſh, and he delighted in a fiery tint; yet ſome of his ſmall pictures are very neatly finiſhed. There is a great inequality as to the merit of the works of Hondius, ſome of them being in every reſpect abundantly ſuperior to others; but there is ſcarce any maſter whoſe compoſitions are ſo eaſily diſtinguiſhable as thoſe of Hondius, by certain particularities in his touch, his taſte of deſign, and his colouring.

Several of his pictures of dogs are much eſteemed; and one eſpecially is mentioned, in which he repreſented thirty different ſpecies of thoſe animals, all being well deſigned, and every diſtinct animal being characteriſed with ſome peculiar air, action, expreſſion, or attitude. As he was exceedingly haraſſed and tormented with the gout, the works of his latter time are more negligently executed than thoſe which he finiſhed in his prime; and, therefore, they very much contribute to leſſen the reputation he had acquired by ſome of his more ſtudied and better finiſhed performances.

His moſt capital picture is the burning of Troy, in which there are a variety of figures, many of them well deſigned and diſpoſed with judgment. Houbraken alſo mentions a candle-light of this maſter's hand, in which appeared a fine oppoſition of light and ſhadow, and the figures were extremely well deſigned and well coloured. He died 1691, aged 53.

HONDO, in *Geography*, a kingdom of Africa, in the Sierra Leone country, bordering on Quoja, between the Grain Coaſt and the river Scherbro.

HONDTSCHOOTE, a town of France, in the department of the North, and chief place of a canton, in the diſtrict of Bergues; 10 miles S. E. of Dunkirk. The place contains 3168, and the canton 11,194 inhabitants, on a territory of 130 kiliometres, in eight communes.

HONDURAS, a province of the domain or kingdom of Guatimala, in the Spaniſh dominions of North America, bounded on the N. by a bay of its own name, on the E. by the Moſquito ſhore and Caribbean ſea, on the S. by Nicaragua, and on the W. by Guatimala and Vera Paz. The extent of this province is reckoned about 390 miles from E. to W., and 150 from N. to S. The country, which conſiſts of mountains, vallies, and plains, is watered by many rivers, and the land is thus much enriched. It abounds with honey, wax, cotton, fine wool, and particularly dyeing woods, and has ſome gold and ſilver mines; the air is good except near low grounds and moraſſes; the ſoil is fertile, and in many parts produces Indian corn thrice in the year, together with wheat, peas, &c. Its paſtures are excellent, and it furniſhes all kinds of proviſions. Its vineyards afford grapes twice in the year; for immediately after the vintage, the grapes are cut again; and the ſecond grapes are ripe before Chriſtmas. For want of cultivation, many parts of this rich country have become deſert. Its chief towns are Valladolid the capital, Truxillo, Omoa, Gracias á Dios, and St. Jago. It derives its chief importance from thoſe tracts on the bay which furniſh logwood. (See *Bay of* Honduras.) The Moſquito Indians have entered into treaties with the Engliſh, who carry on the trade of mahogany and dyeing-woods.

Honduras, *Bay of*, a bay of the Caribbean ſea, adjoining the province of the ſame, and ſituated between Cape Honduras and Cape Catoche, the north-eaſternmoſt point of Yucatan, in lat. 21° 14′. The country, adjacent to this bay, is chiefly inhabited by the Moſquito Indians, who were formerly more numerous, but their population has been diminiſhed by the prevalence of the ſmall-pox. A nation, ſtill populous, has been fixed in the environs of Cape Gracias á Dios. This conſiſts of the Samboes, ſaid to be the deſcendants of the crew of a Guinea-ſhip, which was formerly wrecked in theſe latitudes. Their complexion, their features, their hair, and their propenſities, will ſcarcely allow us to trace them to any other origin. The firſt eſtabliſhment of the Engliſh in theſe regions was formed about the year 1730, at the diſtance of 26 leagues from Cape Honduras. At the diſtance of 54 leagues from this colony is Gracias á Dios, the harbour of which, formed by an arm of the ſea, is immenſe, and tolerably ſafe. It was near this famous cape that the Engliſh fixed themſelves, upon a navigable river, the borders of which are very fertile. Seventy leagues beyound this, theſe people found at Bluefield ſome ſpacious and fruitful plains, an acceſſible river, a convenient harbour, and a rock which might be eaſily made impregnable. In 1769 the three factories did not employ more than 206 white men, as many mulattoes, and 900 ſlaves. Excluſively of the mules and other articles ſent to Jamaica, they ſent this year to Europe 800,000 feet of mahogany, 200,000 pounds weight of ſarſaparilla, and 10,000 pounds of tortoiſe-ſhell. This commerce had been very much carried on by ſmugglers; but in 1763 the liberty of ſelling logwood was ſecured to Great Britain; however, ſhe was not permitted to raiſe forts, and was even obliged to deſtroy thoſe which had been built. The abbé Raynal obſerves, that the wood which grows upon the dry ſoil at Campeachy, is much ſuperior to that which is cut in the marſhes of Honduras; though the laſt-mentioned wood was moſt in uſe, becauſe the price of the former had for a long time paſt exceeded all bounds. Captain Henderſon has lately (*viz.* in 1809,) publiſhed "An Account of the Britiſh Settlement of Honduras," the reſult of his own obſervations and inquiries. The climate, he ſays, is better than that of moſt of our Weſt India iſlands; the air being refreſhed with regular ſea-breezes at all ſeaſons, except during the early part of ſummer, *viz.* the months of April, May, and June. The average heat is 30°. The only ſettlement formed by the Engliſh, which deſerves the appellation of a town, is called Balize, lying at the mouth of a river of the ſame name; which contains about 200 houſes, all built of wood, and raiſed on pillars eight or ten feet from the ground. The ſtores and offices occupy the firſt floor, and the dining and ſleeping rooms are placed on the ſecond. Each houſe has, likewiſe, its upper and lower piazzas, which form the cooleſt retreats in the building. The river Balize is navigable above 200 miles up the country; and ſeveral of our ſettlers have proceeded to that diſtance in queſt of wood. The bay of Honduras is ſprinkled with a great number of ſhoals, rocks, and cluſters of drowned iſlands, which render the navigation dangerous, and which, without ſkilful pilots, has occaſioned many wrecks. The danger is increaſed during the prevalence of the northerly winds, when the weather is generally hazy, and the currents are ſubject to the influence of the winds. The vicinity of Honduras to ſeveral of the Spaniſh ſettlements renders it an appropriate ſtation for the introduction of our manufactures, which has been hitherto ſubject to conſiderable impediments. The induſtry of our ſettlers has been ſo excluſively directed to the wood-trade, that agricultural cultivation has been neglected; though the ſoil is admirably rich, and fitted to produce either the ſugar, coffee, and cotton of our Weſt India iſlands, or the rice and maize of the continent. The fiſheries might alſo be rendered very productive; that which is moſt regarded is the turtle-fiſhery. Some few of the turtle caught here find their way to London; but moſt of them, eſpecially the ſpecies called "Hawk's bill," which yield the tortoiſe-ſhell, are conſumed on the ſpot. The country ſtill remains almoſt wholly covered with wood. The cutting of mahogany takes place twice in the courſe of the year; *viz.* at Chriſtmas and in autumn. The labour is performed by negroes, each gang of whom has a "huntſman," whoſe buſineſs it is to ſearch the woods and diſcover the ſpot where the exertions of his fellow-labourers may be moſt profitably employed. In order to effect his purpoſe, he cuts his way through the woods, and climbs the talleſt trees, in order to ſurvey the ſurrounding country. The colour of the mahogany leaves aids his eye in tracing the moſt abundant ſpot. The mahogany tree is cut about twelve feet from the ground, the axe-man ſtanding on a ſtage. The trunk of the tree furniſhes, of courſe, the wood of largeſt dimenſions; but for ornamental purpoſes the branches are preferable, the grain in them being cloſer, and the veins more variegated. As theſe trees are generally found ſeparate and diſperſed, a mahogany-walk comprehends an extent of ſeveral miles. Their growth is rapid, but leſs ſo than that of the logwood-tree, which is ſaid to attain maturity in five years. The trunks and branches are dragged to the riverſide, put together in rafts, and floated to the coaſt. Moſt of the negroes employed here have been brought from Jamaica, or have accompanied their owners from the United States; no direct importation from Africa having taken place, they are ſubjected to much leſs labour than the ſlaves in our ſugar colonies. The protection afforded by government to the Honduras trade, conſiſts in a convoy being appointed from Jamaica twice in the year, *viz.* in January and July. The annual revenue of the ſettlement is about 5000*l.* ſterling.

Of the aquatic ſpecies of birds around the bay of Honduras, the pelican and cormorant are the moſt predominant, induced to reſort thither for prey by the tranſparency of the ſea on this coaſt. Swallows alſo appear in great numbers in the rainy ſeaſon. They are obſerved to quit in a body, as ſoon as the dawn appears, the Savannah, in which they have reſted during the night, and to aſcend into the air in a compact ſpiral form, like a water-ſpout or column of ſmoke. Having attained a certain height they diſperſe in queſt of food, which forms the occupation of the day. At ſun-ſet their deſcent takes place in the ſame manner, with inconceivable rapidity, and with a noiſe which can be compared only to the ruſhing of a blaſt or the fall of a torrent. On the Moſquito coaſt the flies are ſo troubleſome that the natives are obliged to quit their dwellings in certain ſeaſons, and to paſs their nights in little barks upon the water. Theſe people ſeem to have arrived at that ſtage of ſavage ſociety which belongs to the claſs of "ſmall deſpotiſms." All the affairs of domeſtic life are performed by women; the ſucceſſion to the crown is hereditary; and the royal power is completely deſpotic, abſorbing within itſelf the executive, the legiſlative, and the judicial functions. They manifeſt no trace of religion except the adoration of evil ſpirits; and they have among them neither phyſician nor lawyer, but abound in conjurors. Polygamy is freely allowed; but adultery is puniſhed, though not capitally. They can ſupport long abſtinence from food, but they indulge in the cuſtomary exceſſes of ſavages when they get poſſeſſion of proviſions, continuing their repaſt day and night, except in the ſhort intervals of ſleep, until they have conſumed their whole ſtock. The warriors of the Moſquito tribe may amount to the number of 1500; and ſmall as this force is, they are able to keep their inland neighbours, whoſe manners are much ruder, in a ſtate of dependence. The Moſquitos have an hereditary averſion to the Spaniards, and profeſs great attachment to our countrymen.

Honduras, *Cape*, called alſo *Punta de Caſtilla*, a cape of North America, at the eaſtern ſide of the bay of Honduras. N. lat. 16°. W. long. 86° 16′.

Honduras, *Sea of*, is that part of the North ſea bounded N. by the iſland of Cuba, S. by the Moſquito ſhore, S.W. by the bay of Honduras, W. by the peninſula of Yucatan, N.W. by the gulf of Mexico, E.N.E. by Jamaica, and the Caribbean ſea.

HONDUROS, a town of the iſland of Cuba, 63 miles N.E. of Bayamo. N. lat. 21° 21′. W. long. 76° 4′.

HONE, Nathaniel, in *Biography*, a portrait painter, who practiſed in London, with conſiderable reputation, in oil and miniature, and more particularly in enamel. He was one of thoſe artiſts who were created members of the Royal Academy at its foundation. He died in 1784.

Hone, *Cape*, in *Geography*, a cape on the coaſt of Algiers, called by the natives "Ras Hunneine," and by the ancients "Promontorium Magnum," ſituated, according to Dr. Shaw, in N. lat. 35° 24′. W. long. 1° 0′.

Hone *Key*, a ſmall iſland in the Spaniſh main, at the entrance of Blueſield's bay. N. lat. 11° 30′. W. long. 83° 1′.

Hone, a fine ſort of whet-ſtone, uſed for ſetting razors, pen-knives, &c. (See Whet-*ſtone.*) This is the cos novacula of Linnæus, with ſmall gritty particles. See Cos *Novacula* and Oil-*ſtone.*

It is of a yellowiſh colour, and is vulgarly, but erroneouſly, ſuppoſed to be holly-wood petrified or changed into ſtone, by lying in a petrifying water for a certain ſeaſon.

Of theſe waters there are ſaid to be ſome in Oxfordſhire, that will thus petrify in a very ſhort time.

A ſort of hones is dug near Drogheda in Ireland: ſome have deſcribed theſe as petrified wood, from the vicinity of Lough Neagh.

At Woodthorp, Codnor upper park, and other iron-ſtone mines in Derbyſhire, thin beds of iron-ſtone are found in the binds belonging to the coal-meaſures, which make pretty good hones when cut and ground to a face. See Farey's Derbyſhire Report, vol. i.

Hones, *bed of*, or **Hone**-*pavement*, is one of the tools uſed in the operation of grinding ſpecula for teleſcopes. This is formed of pieces of the fineſt blue hone or whet-ſtone, which are nearly of the ſame breadth and thickneſs, and which, when whetted, appear moſt even and uniform in their colour and grain. Theſe pieces are to be cut into ſquare bits, and having ground one ſide of each concave on the convex marble, to which they are to be applied, with emery or fine ſand, they are to be cemented upon this thick round piece of marble in a kind of pavement, leaving a ſpace of a ſmall ſtraw's breadth between each, and placing their grain in an alternate direction. Mr. Mudge, inſtead of marble, uſes metal made of lead and tin, on which the hones are to be ſo diſpoſed that the lines between them may run ſtraight from one ſide to the other; and by this diſpoſition, the teeth of a fine ſaw, moved along each of the diviſions, will clear away the cement which riſes between the ſtones. This bed of hones ſhould be at leaſt a fourth part larger than the metal which is to be ground upon it. The ſurface of the metal, upon which it is to be cemented, may or may not, at the pleaſure of the workman, be turned of a convexity ſuitable to the gage. As ſoon as the hones are cemented down, and the joints cleared by the ſaw, the tool muſt be fixed in the lathe, and turned as exactly true to the gage as poſſible. By this inſtrument the ſpherical figure of the ſpeculum is completed, and its ſurface rendered fit for the poliſher. See *Plate* VI. *Optics*, *fig.* 2. Smith's Optics, book iii. chap. ii. art. 791. Phil. Tranſ. vol. lxvii. part i. p. 307. See Grinding.

Hone-*wort*, in *Botany*. See Sison.

HONESTY. See Lunaria.

HONEY, mel, is a ſweet vegetable juice, collected by the bee from the flowers of different plants, and depoſited in the cells of the combs. See Bee.

It has been long known, that the bees collect their honey as well as their wax from the flowers of plants; but former writers had no diſtinct knowledge of the ſeveral parts of the flowers which furniſhed theſe induſtrious inſects with two ſuch different ſubſtances. It is now known that the honey is procured from thoſe parts of the flowers which were firſt diſcovered by Linnæus, and to which he has given the name of *nectaria*: theſe are certain veſicles or glands ſituated near the baſis of every petal, and continually ſecreting a nectareous or melleous juice. It is not yet aſcertained from what part of the flower or plant the bees collect the wax: ſome have ſuppoſed that it is furniſhed by the farina contained in the apices of the flowers; but N. Polhill, eſq. an ingenious friend of the editor, of whoſe extenſive and accurate acquaintance with the economy of the bees he has availed himſelf in articles pertaining to this ſubject, aſſures him that this is not the caſe; and that it is ſtill undiſcovered from whence they procure the wax. See Wax.

The bee ſeizes upon this part of the flower, and ſucks from it their honey, or a juice of that nature, which will become honey under her management. She receives this into her body, and carries it home to the hive, where ſhe unloads herſelf by emptying it into the cells which were before prepared to receive it. The bee does not receive the honey in collecting it from the flowers into the body, by means of her trunk, as many have ſuppoſed; for this trunk ſerves only to collect the ſweet juice, in ſmall drops, from the nectaria of flowers. When the trunk is thus loaded with the juice or honey, it depoſits it on the tongue, which is exerted for that purpoſe, and being drawn back into the mouth, conveys it into the œſophagus. The œſophagus of the bee is a long and ſlender canal, paſſing from the mouth into the thorax; towards its termination in that part it is diſtended into a ſort of bag, which forms the firſt ſtomach of the bee. Maraldi ſuppoſed the receptacle of the honey to be a bag, cloſed at the lower end, and only deſtined to receive the honey, and diſgorge it again upon occaſion; but Swammerdam, on a more accurate diſſection of this inſect, found it to be a real ſtomach, opening into another or ſecond ventricle. The firſt ſtomach, when empty, is no more than a white filament, which, being hollow, is capable of receiving the honey; and, when received, it becomes ſwelled and diſtended in proportion to the quantity it contains, and is very narrow at its lower part, where it is joined to the ſecond ſtomach. This is a ſort of white tranſparent bladder, and is uſually much diſtended, and ſo covered with large and broad circular muſcles, that it ſeems to reſemble a tub with many hoops. This ſtomach becomes again very ſlender and narrow at its lower end, where it is joined to the inteſtines. The ſecond ſtomach and the inteſtines of the bee are often found to contain a great quantity of the farina; but the firſt ſtomach contains only honey, and is ſeen, by diſſection, to be furniſhed with all the organs of contraction and diſtenſion which are neceſſary for throwing out its contents. When the honey has undergone a kind of concoction in the ſtomach, and is become much thicker than in its undigeſted ſtate (though the gentleman already referred to apprehends that it undergoes no kind of change in the ſtomach of the bee), it is diſgorged again through the mouth, and not as Swammerdam erroneouſly imagined, through a ſmall orifice in the end of the trunk. The proceſs of this operation may be eaſily diſcovered in glaſs hives, where the cells reach to the glaſs, and have only four ſides of wax, the glaſs ſerving for the other two ſides.

The bee that comes loaded to the cell thruſts its head very deep into it, and diſcharges the honey from its ſtomach in a very little time, and ſeemingly with very little trouble, by the mouth. One bee ſucceeds another till the whole cell is filled. In this work, it has been often obſerved, that what appears to be the laſt quantity of honey diſgorged into the cell is always of a different appearance from the reſt: this is of the nature of a cream, and is always much thicker than the reſt of the honey, which appears of one colour and conſiſtence; it ſeems to be very uſeful in the economy of the work, ſerving at once to keep the honey moiſt, and to prevent its running out by any accident. Though this cream or cruſt appears to be the laſt voided quantity, it is not ſo in reality, for it ſeems to have been gathered together from the firſt; and every freſh quantity of honey is added under, not upon its ſurface. To this purpoſe it is always obſerved, that the bee which comes loaded to the cell does not at once diſcharge its honey into it, but entering into the cell as deep as poſſible, it puts forward the anterior pair of legs, and with them pierces a hole through the cruſt or cream. While this hole is kept open by the feet, the bee diſgorges the honey in large drops from the mouth; theſe, falling into the hole made by the feet, mix with the maſs below, and the bee, before it flies off, new-models the cruſt, and cloſes up the hole; and this is regularly done by every bee that contributes to the general ſtore of the cell.

The ſeveral cells of the combs in every hive are differently filled with honey, and for different purpoſes: ſome is laid up for immediate conſumption, on occaſions of bad weather and the like accidents, or for the uſe of thoſe bees that in good weather ſtay at home to work, and are not ſupplied in any other way by thoſe which have been abroad collecting honey; and ſome is more carefully preſerved and deſtined for the ſupport of the ſwarm in the winter. Whenever any cell is filled with honey, it is always cloſed up, and never opened again, till all the honey in the cells which were not full is expended. The manner in which the bees make the lids or covers of the cells is this: they form a circle or ring of wax juſt within the verge of the cell; to this they add another ſuch ring, and then another within that; and thus the aperture is rendered ſmaller and ſmaller, and by a continuance of the ſame operation is finally cloſed, the lid being compoſed of a vaſt number of concentric circles. This covering is deſigned for preſerving the incloſed honey in a ſtate of proper conſiſtence, for a winter ſtore.

Honey has been ſuppoſed by many to be the only food of the bees who collect it; but this is evidently erroneous. The farina of flowers ſerves as food for young bees, whilſt they are in the form of maggots, but it is not ſo certain whether the old bees eat it or not; after which ſome ſay it is again thrown out of their mouths in form of wax, and uſed in the ſtructure of their cells; but others abſolutely deny this, becauſe the farina of different flowers varies in colour, whereas the wax is uniformly white.

Honey and wax form ſo conſiderable an article in the riches of a kingdom, that M. Reaumur ſtrongly recommended to the court of France, the encouragement of thoſe who raiſe ſwarms of bees, by deducting ſomething from their taxes in proportion to every hive of bees kept by them above a certain number. And as bees are ſo eaſily raiſed, and kept with ſo little expence and trouble, it is a wonder that they are not more generally propagated in the kingdom. One great means of preſerving and multiplying the bees would be the aboliſhing of that barbarous as well as prejudicial cuſtom, which has hitherto very generally prevailed, of deſtroying the whole hive of bees in order to obtain the honey. Reaumur's Hiſt. Inſ. vol. x. p. 89, &c. See Hive.

Honey is an article from which the cottage labourer frequently derives a very beneficial profit; and this would ſtill be conſiderably larger, if greater care was taken to have a more abundant ſupply of flowers in or near the ſituations in which the bees are kept.

There are many circumſtances neceſſary to the forming of good honey, ſuch as a warm and clear air, a good ſtate of health of the bees, and a quantity of aromatic and ſweet flowers in the neighbourhood of their hives. Some naturaliſts ſuppoſe that honey is of a different colour, according to the difference of the flowers or plants from which the bees ſuck it. The ancients eſteemed that of lilies and roſes to be the beſt; and Strabo relates, that there is a kind of honey in Pontus which is a ſtrong poiſon, being procured by bees which feed upon aconite and hemlock. F. Lamberti, however, aſſures us of the contrary, and affirms it to be the beſt honey in the world, on account of the great quantity of baum that grows there. He adds, that there is another very white kind of honey, hard as ſugar, which does not ſtick to the hands. At preſent, the honey of Narbonne, in France, is held to excel all others, on account of the roſemary which abounds there. Bees are uncommonly fond of the lime-tree, the privet, and phillyrea; and in Lithuania, there are large quantities of wild bees, who lodge in hollow trees in woods, and collect their honey chiefly from the lime; ſo that when the ſeaſon happens to be unfavourable at the time of the blowing of the lime, it is ſucceeded by a ſcarcity of honey. However, it is not to be ſuppoſed, that the bee confines itſelf to one particular flower; nor does it appear that the honey collected from one kind of flower differs eſſentially from that which is the produce of another; the only difference being in the quantity, colour, or ſome ſlight flavour from the flower. Excellent honey has been produced where nothing grew but nettles and other weeds.

The honey taken out of the hives in the beginning of ſummer is preferable to that gathered in autumn, ſince the firſt is the ſeaſon in which the bees are moſt vigorous, and the plants in their flowering ſtate.

We have two kinds of honey, the *white* and *yellow*.

The *white*, *mel album*, called alſo *virgin* honey, is that depoſited in clean new cells, which, when firſt formed, are of a pure white colour; but when the combs are old, eſpecially if bees have been bred in then, they become foul and diſcoloured, and vitiate the honey lodged in them. New honey is nearly as fluid as water, by age it acquires a greater degree of conſiſtence, and the cold of winter frequently congeals it. The ſecond kind, or *mel flavum*, is ſqueezed from the combs in a preſs, after having firſt ſoftened them with a little water over the fire. There is alſo an intermediate ſort of a yellowiſh white colour, drawn by expreſſion, without fire. That which runs ſpontaneouſly is purer than the expreſſed; a quantity of the wax and other impurities being forced out along with it by the preſſure, eſpecially when the combs are previouſly heated. The beſt ſort of honey is of a thick conſiſtence, eaſily and totally ſoluble in cold water, of a whitiſh colour, an agreeable ſmell, and a very pleaſant taſte.

Honey, expoſed to a gentle heat, as that of a water-bath, becomes thin, and throws up to its ſurface its waxy impurities, together with the meal or flower ſometimes fraudulently mingled with it, which may be thus ſeparated by deſpumation, ſo as to leave the honey pure, and to form the *mel deſpumatum* or clarified honey. On continuing the heat, there riſes a conſiderable quantity of aqueous fluid, impregnated with the fine ſmell of the honey; the inſpiſſated reſiduum, like the honey at firſt, diſſolves both in water and in rectified ſpirit, and promotes the union of oily and reſinous ſubſtances with watery liquors. By treating the inſpiſſated maſs with moiſt clay, as practiſed by the ſugar-baker for purifying ſugar from its unctuous treacly matter, the unctuous parts of honey may in like manner be ſeparated, and its pure ſweet matter obtained in the form of a ſolid, ſaline, white concrete.

The ſpecific gravity of clarified honey has been fixed at 1.31; but the tenacity of medicated honeys in general is the more uſual teſt of the proper conſiſtence. If a portion of it, when cold, be divided by the edge of a ſpoon, it ought to unite again very ſlowly.

It is obſerved, that the boiling of honey, though it diſſipates great part of its odorous matter, and thus proves in ſome caſes injurious to it, is nevertheleſs in other caſes of advantage. There are particular conſtitutions with which honey diſagrees, and in which very ſmall quantities occaſion gripes, purging, and great diſorders; but boiling deprives it of that quality which produces theſe effects. Neumann's Chem. by Lewis, p. 330. Lewis's Mat. Med. p. 376.

This juice is an uſeful ſweet for medicinal as well as domeſtic purpoſes: it is more aperient and detergent than the ſimple ſweet prepared from the ſugar-cane; and particularly ſerviceable for promoting expectoration in diſorders of the breaſt, and as an ingredient in cooling and detergent gargariſms. For theſe and other ſimilar intentions it is ſometimes mixed with vinegar in the proportion of two pounds of clarified honey to one pint of the acetic acid, boiled down to a proper conſiſtence in a glaſs veſſel over a ſlow fire, and thus forms the oxymel ſimple of the ſhops; it is alſo impregnated with the virtues of different vegetables, by boiling it in the ſame manner with their juice or infuſions, till the watery parts of the juice or infuſion have exhaled and left the active matter incorporated with the honey. See OXYMEL.

Honey contains a quantity of fixed air, and is antiſeptic as well as detergent and diuretic. Sir John Pringle recommends one pound and a quarter to be taken regularly every week in caſes of the gravel, or when the kidnies are loaded with ſand.

Honey is the baſis of ſeveral compoſitions in pharmacy, though in this reſpect it is leſs uſed than formerly. Of honey, with the addition of roſes or violets, mercurialis, &c. (ſee OXYMEL), was made *mel roſatum, mercuriale, helleboratum*, &c. There is alſo a *mel ſcilliticum*, or a preparation of ſquills; *mel paſſulatum*, made with raiſins boiled in hot water; and *mel anthoſatum*, made with roſemary-flowers.

Roſe honey, *mel roſæ*, *roſaceum*, or *roſatum*, is prepared by macerating four ounces of red roſe petals dried in three pints of boiling water for ſix hours, and then ſtraining, and afterwards adding five pounds of clarified honey to the ſtrained liquor, and by means of a water-bath, boiling it cloſely down to a proper conſiſtence.

Honey of *borax*, *mel boracis*, is prepared by mixing a dram of borate of ſoda powdered with an ounce of clarified honey. This combination is uſefully employed as a detergent in aphthous affections of the fauces.

Honey is alſo an ingredient in ſeveral drinks, as mum, metheglin, &c.

The chemiſts alſo draw a water, a ſpirit, an oil, &c. from honey.

Mr. Lemery, in his analyſis of honey, obſerves, that two pounds of fine honey diſtilled in balneo Mariæ, afford ſix ounces of clear water of an inſipid taſte and of the ſmell of honey: this is commonly called the *dew* of honey. A larger quantity of phlegm may be procured by continuing the diſtillation, but it becomes foul. This liquor, though inſipid to the taſte, yet contains a latent acid, for it reddens the turnſole; but it neither ferments with the volatile nor fixed alkalies. The cucurbit being now placed in the ſand heat, there come over four ounces of a yellowiſh pellucid water of an acrid taſte, of a ſtrong ſmell of honey, and ſomewhat empyreumatic: this liquor reddens the turnſole colour more than the former. The fire being increaſed, there ariſe white clouds, which fill the head of the cucurbit and the receiver, and theſe finally condenſe into a third liquor, which is called the ſpirit of honey. This will be about three ounces in quantity, and of a red colour and empyreumatic ſmell, yet with an agreeable flavour, and of an acrid and burning taſte. This is a ſtronger acid than either of the former, and ferments with an alkali.

The fire being again increaſed, more clouds ariſe, and, in fine, there is a fourth liquor produced; this is in quantity about two ounces, of an orange colour, and of an acid taſte, but leſs acrid than the third liquor, as it contains more oil, which ſoftens and ſweetens it. Like the former, it ferments with alkalies, and reddens the colour of turnſole. When the diſtillation is thus finiſhed, there will remain in the cucurbit fifteen ounces and a half of a light ſpungy black coal. (Mem. Acad. Par. 1706.) This is to be then put under a retort for a freſh diſtillation, and a ſtrong fire under this veſſel will raiſe from it ſeven ounces of a reddiſh brown liquor, which ſtains the fingers to an orange colour, of a burnt ſmell, yet with ſomething agreeable in it, and of an acid and very acrid pungent taſte. Beſides this, there come over two drams of a thick black oil, looking like tar; this alſo was of an acrid taſte, which was owing to ſome of the ſalts of the honey being blended with it. There is much more oil contained in the honey, but it does not come over ſeparate but blended with the other liquors; and after they have ſtood ſome days precipitates itſelf from them, and is found ſticking to the ſides and bottom of the veſſel. The matter remaining in the retort is about ſeven ounces of a black coal, of a light ſpungy texture, and of a taſte almoſt inſipid, and only ſeeming to contain a little ſalt. We ſee by this proceſs, that thirty-two ounces of honey yield twenty-four ounces and two drams of liquor, that being the difference in weight, between the honey when firſt put in, and the laſt caput mortuum. Twenty-two ounces and ſix drams are the quantity here preſerved of the ſeveral liquors, the reſt having eſcaped through the junctures of the veſſels, as will always be the caſe in ſuch diſtillations. Id. ibid.

The caput mortuum of this, and ſeveral other diſtillations of honey, the whole making three pounds and a half, were put into an unglazed earthen pot, and calcined over the fire for ten hours; this readily took fire like common charcoal, and burnt till it loſt ten ounces in weight, but without falling into aſhes. The remaining coal had then a more ſaline taſte than before. Any acid liquor poured upon this fermented, as with the common alkalies; and when thrown into water to make a lixivium, it bubbled in the manner of quick-lime thrown into water; and in the common way of making the lixivial ſalts, this yielded a dram and a half of an acrid alkaline one.

It is remarkable, that the calcined caput mortuum of honey contains, like other vegetable aſhes, true particles of iron, which adhere to a knife touched with a magnet.

Honey, *Wild.* St. Adaman, abbot of Hii, in his deſcription of the holy places, obſerves, that in the place where St. John the Baptiſt lived in the Deſert, there are locuſts which the poor people boil with oil, and a ſort of herbs with large, long leaves of a milk colour, and a taſte like that of honey; and that this is what in ſcripture is called *wild* honey. See Acridophagi.

Honey-*bird*, in *Ornithology*. See Trochilus.

Honey-*buzzard*, the Engliſh name of the *Buteo apivorus*. See Falco *Apivorus*.

Honey *of Roſes*. See Rose, and Honey, *ſupra*.

Honey-*comb*, a waxen ſtructure, full of cells, framed by the bees to depoſit their honey, eggs, &c. in.

The conſtruction of the honey-comb ſeems one of the moſt ſurpriſing parts of the work of inſects, and the materials of which it is compoſed, which though evidently collected from flowers of plants, yet do not, that we know of, exiſt in them in that form, have given great cauſe of ſpeculation to the curious. The regular ſtructure of the comb is alſo equally wonderful. When the ſeveral cells in it are examined, it ſhould ſeem that the niceſt rules of geometry had been conſulted for its compoſition, and all the advantages that could be wiſhed or deſired in a thing of that kind are evidently found in it.

The bees, in the ſtructure of this receptacle of their honey, ſeem to have reſolved a geometrical problem, far from an eaſy one, and indeed clogged with ſo many conditions, that it might have puzzled able proficients in that ſcience. This may be expreſſed in theſe words: a quantity of wax being given, to form it into a number of angular and equal cells, of a determinate capacity, but the greateſt that can be made with that quantity of wax, and, at the ſame time, that theſe cells ſhall be ſo diſpoſed as to take up as little room as poſſible in the hive. In order to this laſt condition, it is neceſſary that the cells touch one another, in ſuch a manner, that there be no angular ſpace nor cavity between them. The bees have effected all this by making the cells all hexangular, or tubes of ſix equal ſides; triangular, quadrangular, and ſome other figures; for the cells might have been indeed ſo diſpoſed between one another as to leave no ſpace; but then an equal number of them could not be made with the ſame quantity of wax. The body of the bee being rounded, it will alſo be received into an hexangular cell, without leaving ſuch large ſpaces as it muſt if received into a triangular or ſquare one.

The method of making two ſets of cells in each comb, is alſo admirably contrived to ſave the expence of wax, ſince, had they been made ſingle, every comb muſt have had its peculiar baſe, and every ſet of cells their bottom of wax; whereas one bottom now ſerves to two cells, and there is but one plate of wax in the centre of a double comb. There is, however, this farther difficulty attending it, that the ſeveral cells are not ſo many hexagonal tubes with flat and broad baſes, or tubes of an equal breadth all the way; but they are truly pointed at the bottom, being every one of them a hexangular cell, with a pyramidal baſe, and forming that kind of figure, as Maraldi and Reaumur firſt diſcovered, which requires at leaſt wax for containing the ſame quantity of honey. Each of theſe baſes is compoſed of three equal rhombuſes, and each baſe, in this manner, becomes the baſe of three other cells on the oppoſite ſide of the comb.

This is eaſily demonſtrated to thoſe who underſtand geometry, by means of the ſeveral figures and poſitions of the oppoſite baſes of the cells of the two ſides of the comb; but the moſt familiar explication of it to a common obſerver, is to ſtick three ſmall pins through the baſe of any one cell, each in the centre of the rhomb that makes one ſide of that baſe: if, after this, the comb be turned, the three pins will be found in the centres of three different cells of the oppoſite ſide.

The obtuſe angles of the three equal rhombuſes that form the baſe, are found to be the doubles of an angle, (which often comes under conſideration in queſtions relating to *maxima* and *minima*,) whoſe tangent is to the radius as the diagonal is to the ſide of the ſquare. By this conſtruction, three of the ſix ſolid angles at the baſe, that correſpond to the angles of the hexagon, are equal to each other, and alſo to the ſolid angle at the apex of the figure, each of which ſolid angles is reſpectively formed from three equal, plane, obtuſe angles; and the other three ſolid angles are alſo equal to each other, but each of them is formed by four equal, plane, acute angles, which are the ſupplements of the former obtuſe angles. Monſ. Maraldi found, by menſuration, that the obtuſe angles of the rhombuſes were nearly 110°, and obſerved, that if they were ſuppoſed equal to each other, each of them muſt be 109° 28′; and Mr. Koenig, by the method of infiniteſimals, found, that this angle, in order to employ the leaſt wax poſſible in a cell of the ſame capacity, ought to be 109° 26′. Mr. Maclaurin has alſo demonſtrated, from the principles of common geometry, that the moſt advantageous angle is that which reſults from the ſuppoſed equality of the three plane angles forming the ſolid angle. We ſhall ſubjoin the demonſtration for the ſake of the mathematical reader.

Let G N and N M (*Plate* VIII. *Geometry*, *figs.* 98 and 99.) repreſent any two adjoining ſides of the hexagon, or the ſection of the cell perpendicularly to its length. The ſides of the cell are not complete parallelograms, as C G N K, B M N K, but trapezia, C G N E, B M N E, to which a rhombus C E B *e* is fitted at O E, that has the oppoſite point *e* in the apex of the figure; ſo that three rhombuſes of this kind, with ſix trapezia, may complete the figure of the cell. Let O be the centre of the hexagon, of which C K and K B are adjoining ſides; join C B and K O interſecting in A; and, becauſe C O B is equal to C K B, and K E equal to O *e*, the ſolid E B C K is equal to the ſolid *e* B C O; whence it follows, that the ſolid content of the cell will be the ſame, wherever the point E is taken in the right line K N, the points C, K, B, G, N, and M, being given. It is, therefore, neceſſary to enquire, where the point E is to be taken in K N, ſo that the area of the rhombus C E B *e*, together with that of the two trapezia C G N E, E N M B, may form the leaſt ſuperficies. Becauſe E *e* is perpendicular to B C in A, the area of the rhombus is $AE \times BC$, and that of the trapezia $\overline{CG + EN} \times KC$; the ſum of theſe is $AE \times BC + 2\,KN \times KC - KE \times KC$; and becauſe $2\,KN \times KC$ is invariable, we are to enquire when $AE \times BC - KE \times KC$ is a minimum?

Suppoſe the point L to be ſo taken upon K N, that K L may be to A L as K C is to B C. From the centre A deſcribe in the plane A K E, with the radius A E, an arc E R meeting A L, produced, if neceſſary, in R: let E V be perpendicular to A R in V, and K H be perpendicular to the ſame in H; then the triangles L E V, L K H, L A K, being ſimilar, we have $LV : LE :: LH : LK :: LK : LA :: KC : BC$ by the ſuppoſition, Hence, when E is between L and N, we have $LH + LV (= VH) : LK + LE (= KE) :: KC : BC$; and when E is between K and L, we have $LH - LV (= VH) : LK - LE (= KE) :: KC : BC$; that is, in both caſes we have $KE \times KC = VH \times BC$; and conſequently $AE \times BC - KE \times KC = AE \times BC - VH \times BC = \overline{AE - VH} \times BC = \overline{AR - VH} \times BC = \overline{AH + VR} \times BC$: which expreſſion, becauſe A H and B C do not vary, is evidently leaſt when V R vaniſhes, *i. e.* when E is upon L. Therefore C L B *l* is the rhombus of the moſt advantageous form in reſpect of frugality, when K L is to A L as K C is to B C. But as O K is biſected in A, $KC^2 = OK^2 = 4\,AK^2$, and $AC^2 = 3\,AK^2$, or $BC = 2\,AC = 2\sqrt{3} \times AK$; conſequently, $KC : BC :: 2\,AK : 2\sqrt{3} \times AK :: 1 : \sqrt{3}$; and $KL : AL :: (KC : BC ::)\ 1 : \sqrt{3}$; or $AL : AK :: \sqrt{3} : \sqrt{2}$; and (becauſe $AK : AC :: 1 : \sqrt{3}$) $AL : AC :: 1 : \sqrt{2}$; *i. e.* the angle C L A is that, whoſe tangent is to the radius as $\sqrt{2}$ to 1, or as 14142135 to 10000000; and therefore it is 54° 44′ 8″, and conſequently the angle of the rhombus of the beſt form is that of 109° 28′ 16″.

By this ſolution it is eaſy to eſtimate what ſaving is obtained by means of this conſtruction.

If the baſe were flat, and not of the pyramidal form above deſcribed, then, beſides completing the parallelograms C G N K and B M N K, the ſurface of the baſe had would be $3\,CB \times AK$; what they really do form amounts in ſurface to the ſame parallelograms, and $3\,CB \times AH$; the ſavings therefore amount to $3\,CB \times \overline{AK - AH} = 3\,CB \times AH \times \frac{\sqrt{3} - \sqrt{2}}{\sqrt{2}}$, which is almoſt a fourth part of the pains and expence of wax they beſtow above what was neceſſary for completing the parallelogram ſides of the cells.

Mr. Maclaurin has alſo demonſtrated, that the plane angles C L B, C L N, and B L N, which form the ſolid angle at L or the apex at *l*, are equal to each other; from which it is obvious, that the four acute, plane angles, which form the ſolid angle at C or B, are likewiſe mutually equal. It may be alſo added, that if the cells had been of any other form than hexagonal, and the baſes had ſtill been pyramidal, theſe muſt have been terminated by trapezia, and not by rhombuſes, and therefore they would have been leſs regular, becauſe O A and A K would have been unequal. Nor could there have been room for ſuch an advantageous or frugal conſtruction as that we have deſcribed, becauſe the ſolid contents of the cell would have increaſed with the right line K E. See Phil. Tranſ. abr. vol. ix. p. 2, &c.

This conſtruction not only occaſions a very great ſaving of the wax or matter of the comb; but beſides this, there is another great advantage, which is, that the angles, reſulting from this combination of the baſes, greatly ſtrengthen the whole work.

The matter of which the comb is made, coſts the bees ſo much pains and labour in collecting, that it is no wonder they are careful and ſparing of it in the work. The ſides of the cells are all much thinner than the fineſt paper, and yet they are ſo ſtrengthened by their diſpoſition, that they are able to reſiſt all the motions of the bee when within them, as they are very frequently obliged to be. The effect of their thruſting their bodies into the cells, would be the burſting of thoſe cells at the top, were not this well guarded againſt. But to prevent this, the creatures extend a cord or roll of wax round the verge of every cell, in ſuch a manner, that it is ſcarcely poſſible they ſhould ſplit in that particular part. This cord or roll is at leaſt three times as thick as the ſides of the cell, and is even much thicker and ſtronger at the angles of the cell than elſewhere; ſo that the aperture of each cell is not regularly hexagonal, though its inner cavity be perfectly ſo.

The baſes of the cells are not always perfectly trilateral; ſometimes, inſtead of the three rhombs they ſhould be compoſed of, they conſiſt of four pieces, the bee having begun her work wrong; but then it is admirable to obſerve, how nicely the two ſmaller pieces are afterwards joined, that the angle they make may be as nearly as poſſible equal to that of one of the rhombs, ſo that the baſe of the cell ſtill remains very nearly trilateral.

It would be a moſt deſirable thing to ſee the bees at work in their making theſe elegant and regular fabrics; but it is ſcarcely poſſible to ſee any thing of this kind diſtinctly, even with the advantages of glaſs hives; for no bee ever works ſingly on this occaſion, but wherever the fabric is erecting, there are numbers together, all trying to aſſiſt one another; and their motions are ſo ſwift, and ſo hid by their ſtanding before one another, that very little is to be ſeen of them. New bees are every moment coming to the place, and old ones going away; and very frequently thoſe which arrive late are diſpatched away immediately after they arrive. There are only ſome very ſhort moments in which the glaſſes of the hives can give a view of the creatures regularly employed in their work, for the moment that one ſees a bee at work in building, that moment we ſee one either fly off, or ſome other bee get before her, ſo as to hinder the view.

Theſe momentary ſights, however, are ſufficient to make it plain, that the bee uſes her teeth in modelling and faſhioning the wax. The ſide of a cell is always received between the two teeth on this occaſion, and by means of repeated blows on each ſide from each tooth, the ſide is brought to a proper thinneſs, and the wax is by the ſame means wrought up to a proper conſiſtence and firmneſs.

The celerity with which a ſwarm of bees received into a hive, where they find themſelves lodged to their minds, bring their works of the combs to perfection, is amazing. In a week's time, when the weather favours, the half or two-thirds of a hive will be filled with combs. There are vaſt numbers at work all at once, and that they may not incommode one another, they do not work upon the firſt comb till it is finiſhed; but when the foundation of that is laid, they go to work upon another; ſo that there are often the beginnings of three or four ſtories made at once, and ſo many ſwarms allotted to the carrying on the work of each.

The ſeveral combs are all placed parallel one to another, and hang perpendicularly from the top of the hive to the bottom; they begin each comb at the top or upper part of the hive, and carry it down to the floor, from ſide to ſide; and there is ſuch a ſpace left between them, that the bees can eaſily paſs between: there are alſo holes made through the ſubſtances of the ſeveral combs, by which they paſs from the ſpace that lies between one pair of combs and another. They often place a part of the combs in a contrary direction to the reſt; ſo that while the others are placed horizontally, theſe ſtand perpendicular: there are alſo ſeveral other directions, in which they are diſpoſed, which are eaſily accounted for from the nature of the place, and are always found to be the very beſt that could be uſed for the occaſion.

Though the ſides of all the cells are extremely thin, yet the combs are very heavy when full of honey. This might endanger their breaking their hold, if only ſuſtained from the top; and for this reaſon, the bees give them ſeveral additional ſupports in whatever places they can, often faſtening them in many places one to another, and often fixing them to the ſides of the edifice by large and ſolid lumps of wax.

It has generally been ſuppoſed that every bee of a ſwarm has its particular cell in ſome comb which was its own, and contained honey for its peculiar food; but the uſe of the glaſs hives has ſhewn us that all the cells are uſed in common. Reaumur, Hiſt. Inſ. vol. ix. p. 282. vol. x. p. 21, &c.

HONEY-*comb*, in *Gunnery*, is a flaw in the metal of a piece of ordnance, when it is ill caſt and ſpongious.

HONEY-*comb-ſtone*, in *Natural Hiſtory*, the name given by many authors to a ſpecies of foſſile coral, which is uſually found in large maſſes, and thoſe full of large hexagonal cells, reſembling thoſe of a honey-comb. Theſe are but lightly ſtriated, and uſually run deep into the ſtone.

HONEY-*comb-ſtone*, or Lapis favaginoſus, is enumerated by Dr. Woodward in his Method of Foſſils, and is mentioned by Dr. Plot as found in the north-eaſt part of Staffordſhire, which refer, it ſeems, to a ſpecies of coralline in the lime-ſtone rocks.

HONEY-*dew*, a term frequently applied to a clammy ſaccharine ſubſtance, which is often ſeen covering the leaves and other parts of different kinds of trees and plants, at ſome particular ſeaſons of the year. It does not appear that the cauſe of this extraordinary appearance is yet fully underſtood, as it has not, by any means, been well aſcertained, whether it derives its origin from external circumſtances, or ſome morbid affection of the vegetables themſelves. The author of Phytologia appears to incline to the latter ſuppoſition, and conceives it to be an excretion from the parts of the plants which are affected with it. Indeed, it ſeems not improbable but that there may be ſome local derangement in the parts of the plants which are covered with this ſticky material.

Gaſſendus holds, that a viſcid juice, tranſpiring out of the leaves, helps to compoſe this honey; or to convert the dew, falling on them, into a honey ſubſtance, which before had nothing of it: hence he accounts for the reaſon why we find it on ſome trees and not on others.

This honey-dew, falling on the ears and ſtalks of wheat, beſmears them with a different colour from the natural; and, being of a clammy ſubſtance, ſo binds up the young, tender, and cloſe ears of the wheat, by the heat of the ſun, that it prevents the growth and completing of the perfect grain therein.

Hops, when in flower, are ſubject to the diſtemper called the honey-dew, which appears in the form of a meal, and is found by the microſcope to contain the eggs of ſmall inſects, which fly about in ſwarms near the time when the hop is in flower, and gnaw the leaves and ſhoots. Several methods have been propoſed for preventing the damage ariſing from this dew; particularly by ſurrounding the hop-hills with hot dung, or cauſing wood-aſhes to be ſcattered with the wind over the hops at the time when the mealy dew falls. But the moſt effectual way of preventing its ill effects is to ſtrip off the leaves, whereby the ſmall inſects contained in it periſh at once, and before freſh leaves ſpring forth, their ſeaſon of breeding is paſt.

A ſhower of rain, ſucceeding preſently after the fall thereof, or the wind blowing ſtiffly, are the only natural remedies againſt it. See APHIS, DEW, MILDEW, and *Perſpiration of* PLANTS.

HONEY-*flower*, in *Botany*, &c. See MELIANTHUS.

HONEY-*graſs*, the common name of a ſort of graſs that is occaſionally found in ſhady ſituations, but which is not found of much utility as the food of domeſtic animals. See MELLICA.

HONEY-*guide*, in *Ornithology*. See CUCULUS *Indicator*.

HONEY *Iſland*, in *Geography*, a ſmall iſland in the Atlantic, near the coaſt of Guinea. N. lat. 10° 18′. W. long. 15°.

HONEY-*locuſt*, or *three-thorned Acacia*, in *Botany*. See GLEDITSIA.

HONEY-*ſuckle*, in *Botany* and *Gardening*. See LONICERA.

HONEY-*ſuckle*, *African-fly*. See HALLERIA.

HONEY-*ſuckle*, *American upright*. See AZALEA.

HONEY-*ſuckle*, *French*. See HEDYSARUM.

HONEY-*ſuckle Clover*, in *Agriculture*, a term not unfrequently made uſe of to ſignify white clover. It is likewiſe often ſimply termed honey-ſuckle. See CLOVER, and *White* CLOVER.

HONEY-*ſuckle*, *Trumpet*. See HONEY-*ſuckle*, ſupra.

HONEY-*ſuckle Graſs*. See TREFOIL.

Honey-*wort*. See Cerinthe.

HONEYYOE, in *Geography*, a lake of America, in the Geneſſee country, New York, W. of Canandarque lake, five miles long and three broad.

HONFLEUR, a town of France, in the department of the Calvados, and chief place of a canton, in the diſtrict of Pont l'Evêque; ſeven miles N.N.E. of Pont l'Evêque. The place contains 9,600, and the canton 16,107 inhabitants, on a territory of 100 kiliometres, in 16 communes. N. lat. 49° 25'. E. long. 0° 19'.

HONGIE, a town of Auſtrian Poland, in Galicia; 30 miles W.S.W. of Halicz.

HONGILAX, a town of Sweden, in the government of Abo; 35 miles S. of Biorneborg.

HONG-TCHEOU, a town of the kingdom of Corea; 20 miles S.S.E. of Haimen.

HONG-TSE, a large lake of China, which diſcharges its waters into the Hoang; 60 miles from the ſea.

HONHAY, a town of Bengal; nine miles S.S.E. of Ramgur.

HON-HOTOU, a lake of Chineſe Tartary; 24 miles in circumference. N. lat. 48° 29'. E. long. 92° 46.

HONI *ſoit qui mal y penſe,* q. d. *evil to him that thinks evil;* the motto of the moſt noble order of the knights of the Garter. See Garter and Motto.

HONIDA, in *Geography*, a town of Perſia, in the province of Irak; 45 miles E.N.E. of Gnerden.

HONIGFELTZ, a town of Pruſſia, in Pomerelia; 15 miles S. of Marienburg.

HONIMAO, or Uliasser, one of the Molucca iſlands, about 9 miles long, and from 3 to 5 wide. The land is fertile, and its chief productions are rice and cloves. S. lat. 3° 30'. E. long. 129° 2'.

HONINGDAEL, a town of Norway, in the dioceſe of Drontheim; 80 miles S.W. of Romſdal.

HONITON, is a borough, market town, and pariſh in the hundred of Axminſter, and county of Devon, England. It conſiſts principally of one broad handſome ſtreet, running from eaſt to weſt, and another croſſing it at right angles: through the former flows a ſmall ſtream, from which the inhabitants are ſupplied by a dipping place oppoſite to almoſt every door. The buildings are moſtly modern; the town having ſuffered conſiderably by fire at different times. In the year 1747, three-fourths of the houſes were reduced to aſhes, and ſeveral hundreds of the labouring inhabitants thrown out of employ. In 1765, nearly 180 dwellings, and other buildings, were deſtroyed: another fire, in 1790, conſumed 30 more; and a fourth, in 1797, the ſame number, together with the bank. The town is now in a ſtate of great improvement; and the buildings are in general covered with ſlate: the number of houſes returned, under the late act, was 557; the inhabitants 2377. The chief article of manufacture is broad lace, and edgings, of which conſiderable quantities are diſpoſed of in the metropolis. The pariſh church is ſituated on an eminence at the diſtance of about half a mile from the town. It was originally a ſmall chapel for mendicant friars, but was enlarged about the year 1482, chiefly at the expence of Courtenay, biſhop of Exeter; who alſo gave the curious ſcreen which ſeparates the chancel from the nave. The ancient parochial church is ſuppoſed to have ſtood in the town on the ſpot now occupied by Allhallow's chapel; which is a neat ſtructure, with a ſquare embattled tower of flint; and was erected by ſubſcription, in place of an older edifice, about the year 1765. Beſides theſe places of religious worſhip, here are three meeting-houſes for the reſpective denominations of Independents, Baptiſts, and Preſbyterians. The education of the poorer claſſes is partly provided for in a ſmall free-ſchool for boys, and a ſchool of induſtry for girls: the latter is ſupported by the ſubſcription of females. This town poſſeſſed the privilege of a market previous to the reign of king John, by whoſe direction the day on which it was held was changed from Sunday to Saturday. Honiton ſends two members to parliament; but, though an ancient borough by preſcription, it was only twice repreſented prior to the time of Charles I.: the firſt return was made in the twenty-eighth year of Edward I. The right of election, which was formerly extended to every houſekeeper not receiving alms, is now veſted ſolely in the burgage holders paying ſcot and lot: the number of voters is about 350. The government of the town is under the direction of a portreve and bailiff, who are annually choſen at the court of the lord of the manor. Honiton is 159 miles diſtant from London. Polwhele's Hiſtory and Antiquities of Devonſhire, fol.

HONNOCHETO Lake, a lake of Weſt Florida. N. lat. 31° 22'. W. long. 91° 27'.

HONOMINIES, a river of America, in the N.W. territory, which runs S.E into Puan bay. Between the head of this river and lake Superior is a ſhort portage.

HONOPOLOGAN, a town of the iſland of Ceylon; 55 miles N.N.W. of Parroah.

HONORAT, a ſmall iſland in the Mediterranean, near the coaſt of France. N. lat. 43° 30'. E. long. 7° 7'.

HONORIACI, in *Antiquity*, a ſpecies or order of ſoldiery under the eaſtern empire, who introduced the Goths, Vandals, Alani, Suevi, &c., into Spain.

Didymus and Verinianus, two brothers, had, with great vigilance and valour, defended the paſſages of the Pyreneans againſt the Barbarians, for ſome time, at their own expence; but being at length killed, the emperor Conſtantius appointed the honoriaci to defend thoſe paſſages, who, not contented to lay them open to all the nations of the North, then ravaging the Gauls, joined themſelves to them.

HONORIS Respectum, *Challenge propter*, in *Law*. See Challenge.

HONORIUS, emperor of the Weſt, in *Biography*, ſecond ſon of the great Theodoſius, was born in 384; obtained the title of Auguſtus, with his brother Arcadius, in 393, and ſucceeded to his portion of the empire at his father's death in 395. The reins of government were, during his minority, placed in the hands of the illuſtrious general Stilicho, whoſe daughter he married in 398. As his character opened he appeared ill adapted to his high ſtation, and was addicted to puerile amuſements, void alike of vigour and talents, and in every reſpect unfit to wield the ſceptre of a mighty people. The times, however, wore a ſerious aſpect; and the danger to which the empire was expoſed required wiſdom and fortitude. The revolt of the Goths, and an invaſion of Italy by Alaric, with whom Stilicho had been obliged to make a kind of compromiſe, ſo alarmed the young emperor, that in 403 he fled from his palace, and was for a time beſieged by the Goths in a town of Liguria, in which he had taken ſhelter. His faithful general Stilicho came to his releaſe, and, by the defeat of Alaric, freed Italy from preſent danger. The pageant prince was led to Rome, and had the honour of a triumph, at which, for the laſt time, there was an exhibition of the inhuman combats of gladiators. After this the emperor fixed the ſeat of empire at Ravenna: he conquered his enemies by his generals, being reſolved never more to expoſe his ſacred perſon to any riſk: he ſuffered himſelf to be governed by his miniſters, who took advantage of their imperial maſter's indolence and inactivity. He died of a dropſy, in the 39th year of his age. Under Honorius and his brother the Roman power was divided into two different empires. The ſucceſſors of Honorious, who fixed their reſidence at Rome, were called emperors of the Weſt, and the ſucceſſors of Arcadius, who ſat on the throne of Conſtantinople, were diſtinguiſhed by the title of emperors of the Eaſtern Roman empire. Honorius was twice married, but left no iſſue. Gibbon. Univer. Hiſt.

Honorius I., pope, ſon of Petronius, a perſon of conſular dignity, was choſen to fill the Roman ſee on the death of Boniface V., in the year 626. The moſt remarkable circumſtance in the life of this pope was, his having been induced to give his ſanction to the opinion of the Monothelites, who maintained that in Chriſt there was only one will, one operation, for which he was ſolemnly condemned by the ſixth general council, in the pontificate of pope Agatho. Some account of the ſects MONOTHELITES, and MONOPHYSITES, will be found under their reſpective articles. Honorius probably knew little about the matter, nor was able to attach any preciſe and definite meaning to the expreſſions which he was led to make uſe of. He died in 638, after a reign of nearly thirteen years. He is greatly praiſed for having employed diligence and zeal in embelliſhing churches, and other conſecrated places, with the moſt pompous and magnificent ornaments. Some of his letters are extant in the fifth volume of the "Collect. Concil." He is author of an epigram on the apoſtles looking up towards heaven with aſtoniſhment at the aſcenſion of Chriſt, which is to be found in the twelfth volume of the Bibl. Patr. Moreri. Bower.

Honorius II., pope, whoſe original name was Lambert, was a native of the province of Bologna. Having embraced the eccleſiaſtical life he was preferred by pope Paſchal II. to the epiſcopal ſee of Veletri, and afterwards tranſlated to that of Oſtia. Upon the death of Calixtus in 1124, Honorius was elected to the popedom. Soon after his conſecration he iſſued a ſentence of excommunication againſt William, the ſon of Robert count of Normandy, for having married within the forbidden degree of conſanguinity, and for having publicly burnt a letter ſent to him by the pope's legate, in which his marriage was declared null. On the death of the emperor Henry V., in the year 1125, Honorius ſent his legates into Germany, to aſſiſt at the election of a new king, in whoſe preſence Lotharius was anointed with the uſual ceremonies. In the following year the pope ſucceeded in perſuading Henry I. of England to admit a legate into his kingdom, whoſe uſurpations quickly provoked the ſpirited oppoſition of the clergy and laity. In 1127, upon the death of William, duke of Apulia, without leaving any iſſue, his uncle Roger, count of Sicily, paſſed over into Italy, and took poſſeſſion of his nephew's dominions as his next heir. But Honorius having heard of his proceedings, pretended that the late duke had, by his laſt will, left his dominions, and whatever elſe he was poſſeſſed of, to St. Peter, and inſtantly denounced a ſentence of excommunication againſt Roger. The queſtion was diſputed at the point of the ſword, but the army of the prince prevailed againſt that of the pope, and his holineſs was glad to grant him the inveſtiture to the duchy. Honorius died in 1130. Twelve of his letters are preſerved in the tenth volume of the Collect. Concil. Moreri. Bower.

Honorius III. pope, whoſe former name was Cencius Sabelli, was a deſcendant from an illuſtrious family, and a native of Rome, where he diſcharged ſeveral eccleſiaſtical employments with great reputation, and was held in high reſpect for his learning and probity. In 1216, having already filled the poſts of cardinal-deacon and cardinal-prieſt, he was unanimouſly elected pope. The firſt act of his pontificate was to ſend letters to all Chriſtian princes to acquaint them with his promotion, and to exhort them to ſend ſuccours, without delay, to the armies of the cruſaders in the Eaſt. Their ſucceſs was the object of his utmoſt ſolicitude; as was likewiſe the deſtruction of the Albigenſes in France, which he inſtigated the Catholics to attempt, by every method of perſuaſion adapted to produce an effect on credulous or ſuperſtitious minds. In 1217, Henry, emperor of Conſtantinople, dying without iſſue, the princes of the cruſade choſe Peter, count of Auxerre, his brother-in-law, for his ſucceſſor, who, as ſoon as he heard of his election, left France, together with his wife, and repaired to Rome, where they were crowned by Honorius. In the year 1219, Reginald, king of the Iſle of Man, at that time an independent kingdom, apprehenſive that it might be invaded and ſubdued by the kings of England, reſolved to engage the protection of the ſovereign pontiff by ſurrendering himſelf a vaſſal of the apoſtolic ſee. He accordingly made a donation of the whole iſland to Honorius as fief of the Roman church, and afterwards received the inveſtiture of it, upon binding himſelf and his heirs to pay a yearly ſtipulated ſum to the pope as an acknowledgment of vaſſalage. From this time the pope was eager in the attempt to diſpoſſeſs the infidels of the Holy Land, and was particularly deſirous of engaging in the cauſe the emperor Frederic II. But this prince excuſed himſelf from time to time by different pleas, which his holineſs was obliged to admit, till at length, in 1227, he died, after a pontificate of nearly eleven years. Honorius was a man of conſiderable learning for the age in which he lived, and was author of ſeveral works, of which there are ſtill extant, "Sermons;" the "Life of Pope Celeſtine III.;" "A Statement of all the Revenues of the Roman Church," and many others of leſs moment. Several of his letters are inſerted in the eleventh volume of the Collect. Concil. Moreri. Bower.

Honorius IV. pope, who, before his elevation to the popedom, was called James Sabelli, or Savelli, was deſcended from the ſame family with Honorius III., and was created cardinal deacon by pope Urban VI. in 1261. In 1285 he was elected pope, as ſucceſſor to Martin IV., and on this occaſion he aſſumed the name of Honorius IV. He was ſo much afflicted with the gout, that he was unable to ſolemnize the maſs in a proper manner, and only in a ſitting poſture; but he had a mind equal to all the difficulties of his ſituation. One of his earlieſt acts was to renew the anathemas which his predeceſſor had fulminated againſt Peter of Arragon, and by cauſing a cruſade to be preached againſt him in France, he raiſed a powerful army in that country, at the head of which king Philip entered Arragon, and gained a bloody victory over Peter. That prince died in a ſhort time after the battle, and by his will deviſed the kingdom of Arragon to his ſon Alphonſus, and that of Sicily to his ſon James. Honorius no ſooner heard of his death, and the diſtribution which he had made of his territories, than he iſſued his bull, commanding Alphonſus to releaſe, without delay, Charles, prince of Salerno, who had been taken priſoner by his father's fleet, and, at the ſame time, ordering James to quit the iſland of Sicily, and to deliver it up to Charles as the lawful heir. As thoſe princes paid no regard to his holineſs's bull, he excommunicated them, at three different times, in the year 1286, and laid the whole iſland of Sicily under an interdict. Honorius condemned and ſuppreſſed a new ſect founded by Gerhard Sagarelli, who ſtyled themſelves "The Order of the Apoſtles," or "The Apoſtolic Brethren." But the objects apparently neareſt the heart of Honorius were the extenſion of the papal power againſt all daring opponents, and the triumph of the cruſaders over the infidels. His firſt attention was devoted to the former; and in ſubſerviency to it, he had projected a deſign of uniting all the Chriſtian princes in a holy league againſt the two kings of Arragon and Sicily. While, however, he was wholly intent upon carrying it into execution, he was cut off by death, in 1287, when he had but juſt completed the ſecond year of his pontificate. He is ſaid to have been eminent for wiſdom, temperance, and a ſound diſcretion; and as a proof of his regard to the intereſts of learning, he made proviſion for the eſtabliſhment of a college at Paris, for the ſtudy of the Oriental languages, though he did not live to ſee the completion of ſuch an inſtitution. He confirmed the order of the hermits of St. Auguſtine, and that of the Carmelites, which had been only tolerated by the ſecond council of Lyons. Some of his letters are preſerved. Moreri. Bower.

HONOUR, among the *Ancients*, was worſhipped as a divinity, and had a temple erected to it, which had no entry but through the temple of Virtue; in order to teach men that true honour was only to be acquired by the practice of virtue. In conformity to this wiſe maxim, Virtue was ſometimes painted with wings, becauſe ſhe procured honour and victory to thoſe who ſtudied her. Plutarch alſo obſerves to the ſame purpoſe, that they ſacrificed to Honour with the head uncovered; it being uſual to uncover upon meeting with thoſe who by their virtues have acquired honour in the world; and we learn from Pliny, that Fab. Rutilianus was the firſt who made a law, that on the Ides of July the Roman knights ſhould march on horſeback from the temple of Honour to the capitol.

Honour is repreſented on many medals under the figure of a man holding a pike, and ſometimes an olive branch, in the right hand, and a cornucopia in the other.

Beſide its literal ſenſe, wherein it denotes a teſtimony or token of eſteem or ſubmiſſion, honour is particularly applied in our cuſtoms to the more noble kind of ſeignories, or lordſhips, whereof other inferior lordſhips or manors hold or depend. See Seignory.

As a manor conſiſts of ſeveral tenements, ſervices, cuſtoms, &c. ſo an honour contains divers manors, knights-fees, &c. See Manor.

It was alſo formerly called *beneficium*, or *royal fee*, being always held of the king in capite. Spelman.

Anciently honour ſignified the ſame as *baronia*.

Honour, *Counſellors of*, or *Honorary Counſellors*, are ſuch as have a right to enter or ſit in aſſemblies, courts, &c. to deliberate or give judgment in the ſame, though they do not regularly and properly belong to them.

The French call *chevaliers d'honneur*, *knights* or *gentlemen of honour*, the gentlemen uſhers of queens and princeſſes, who attend them, give them their hand, &c. See Usher.

Honour, *Court of*. See Court *of Chivalry*.

Honour *Courts* are held within the honours, or ſeignories, above-mentioned.

Honour, *Maids of*, are young ladies in the queen's houſhold, whoſe office is to attend the queen when ſhe goes abroad, &c. In England they are ſix in number, and their ſalary 300*l. per annum* each.

Honour, *Pages of*, are officers both of the king's and queen's houſhold, under the maſter of the horſe. Of the former there are four, whoſe annual ſalary is 260*l.* each; and of the latter two, with a ſalary of 150*l.* each.

Honour *of a Peer*. See Peer.

Honours *of the Louvre*, among the *French*, are certain privileges annexed to divers dignities, or offices, particularly thoſe of duke, peer, chancellor, &c. as to enter the Louvre in a coach, to have the tabouret, or ſtool, in the queen's preſence, &c.

Honours *of the Church* are the rights belonging to the patron, &c. as a ſeat and ſepulchre in the chancel, to be firſt ſerved with the conſecrated bread and wine, &c.

Honours *of the City* are the public offices or employments thereof. He who has been conſtable, overſeer of the poor, and churchwarden of his pariſh; common-councilman, alderman, and laſtly mayor; has paſſed all the honours of the city.

Honours *of the Houſe* are certain ceremonies obſerved in receiving viſits, making entertainments, &c. performed either by the maſter himſelf, or by ſome perſon appointed for that purpoſe; as to go and receive the gueſts, to conduct them out again, to ſee they be well ſeated, and, in ſhort, to perform all the civilities and ceremonials of polite hoſpitality.

Honours are alſo applied to the principal part of the apparatus of great ceremonies; as coronations, conſecrations, chriſtenings, &c. Such are the oil, tapers, &c.

In obſequies they anciently repreſented the honours, that is, the ſhield, creſt, ſword, gantlets, ſpurs, banner, horſe, &c.

Honours, *Funeral*, are the ceremonies performed at the interment of great men; as hangings, hearſes, funeral harangues, &c.

Honours, *Military*. All armies ſalute crowned heads in the moſt reſpectful manner, colours and ſtandards dropping and officers ſaluting. Their guards pay no compliment except to princes of the blood, and that by courteſy in the abſence of crowned heads.

A field-marſhal is to be ſaluted with the colours and ſtandards of all the forces, except the horſe and foot-guards, and excepting when any of the royal family ſhall be preſent; but in caſe a field-marſhal is colonel of any regiment, or troop of horſe, or foot guards, he is to be ſaluted by the colours or ſtandards of the regiment or troop he commands.

Generals of cavalry and infantry, upon all occaſions, are to have the march beat to them, and to be ſaluted by all officers, thoſe bearing the colours excepted.

Lieutenant-generals of cavalry and infantry are, upon all occaſions, to be ſaluted by all officers. They are to have three ruffles given them with preſented arms.

Major-generals are to have two ruffles with preſented arms.

Brigadier-generals are to have one ruffle with preſented arms.

To colonels their own quarter-guards in camp turn out, and preſent their arms, once a day, after which they only turn out with ordered arms.

To majors their own guards turn out with ordered arms once a day; at other times they ſtand by their arms.

When a lieutenant-colonel or major commands a regiment, their own quarter-guards pay them the ſame compliment as is ordered for the colonel.

The maſter-general of the ordnance is to have the ſame reſpect and honours paid to him as the generals of horſe and foot.

Honours to be paid by the Cavalry.—A general of cavalry or infantry is to be received with ſwords drawn, kettle-drums beating, trumpets ſounding the march, and all the officers to ſalute, except the cornet bearing the ſtandard.

A lieutenant-general is to be received with ſwords drawn, trumpets ſounding twice the trumpet flouriſh, as in drawing ſwords, and all the officers to ſalute, except the cornet bearing the ſtandard; but the kettle-drums are not to beat.

A major-general is to be received with ſwords drawn, one trumpet of each ſquadron ſounding once the trumpet flouriſh, as in drawing ſwords; no officer to ſalute, nor kettle-drum to beat.

A brigadier-general is to be received with ſwords drawn ; no trumpet to ſound, nor any officer to ſalute, nor kettle-drum to beat.

All officers in the command of forts or garriſons, have a right to the complimentary honours from the troops under their command, which are due to the rank one degree higher than the one they actually poſſeſs.

Manner of paying honours.—The king's ſtandard, or colour in the guards, is never to be carried by any guard, except that which mounts on his majeſty's perſon.

The firſt ſtandard, guidon, or colour of regiments, which is the union colour, is not carried by any guard, but that on the king, queen, prince of Wales, or commander in chief, being of the royal family ; and, except in thoſe caſes, it ſhall always remain with the regiment.

When general officers, or perſons entitled to a ſalute, paſs in the rear of a guard, the officer is only to make his men ſtand ſhouldered, and not to face his guard to the right about, or beat his drum.

All ſentries are to pay a due reſpect to every officer who paſſes by their poſts, but are to keep their proper front while paying the compliment.

All governors, whoſe commiſſions in the army are under the degree of general officers, ſhall have, in their own garriſons, all the guards turn out with reſted arms, and beat one ruffle ; and though the main guard turns out with reſted arms every time he paſſes, yet they give him the compliment of the drum but once a day ; but all the other guards beat as often as he appears near them.

If they are general officers likewiſe, they are then to have the further compliments paid them, by the ſeveral beatings of the drum, as practiſed in the army.

Regulation of honours to be paid to admirals.—Admirals, with their flags on the maintop, are to have the ſame reſpect from the troops as generals of cavalry and infantry ; that is, upon all occaſions to have a march beat to them, and to be ſaluted by all the officers, thoſe bearing the colours excepted.

Vice-admirals are to have the ſame reſpect as lieutenant-generals of cavalry and infantry ; that is, upon all occaſions to be ſaluted by all the officers in the garriſon, the drummers beating three ruffles.

The rear-admirals are to have the ſame reſpect as major-generals, who have two ruffles, and not to be ſaluted by any officer.

Commodores with broad pendants have the ſame reſpect as brigadier-generals ; which is to have one ruffle.

Rank and precedence between ſea and land officers.—The admiral, or commander-in-chief of his majeſty's fleet, is to rank with a field-marſhal of the army.

The admirals with their flags on the main-top-maſt-head, are to have rank with generals.

Vice-admirals are to have rank as lieutenant-generals.

Rear-admirals are to have rank as major-generals.

Commodores with broad pendants are to have rank as brigadier generals.

Captains commanding poſt-ſhips, after three years from the date of their firſt commiſſion for a poſt-ſhip, are to have rank as colonels.

All other captains commanding poſt-ſhips, are to have rank as lieutenant-colonels.

Captains of his majeſty's ſhips or veſſels, not taking poſt, are to have rank as majors.

Lieutenants of his majeſty's ſhips are to have rank as captains.

The rank and precedence of ſea-officers, in the claſſes above-mentioned, are to take place according to the ſeniority of their reſpective commiſſions.

Poſt-captains commanding ſhips or veſſels that do not give poſt, rank only as majors during their commanding ſuch veſſels.

No land-officer is to command any of his majeſty's ſquadrons or ſhips, nor any ſea-officer to command at land ; nor ſhall either have a right to demand military honours due to their reſpective ranks, unleſs they are upon actual ſervice.

All guards and centinels are to pay the ſame compliments to the officers of the royal navy, as are directed to be paid to the officers of the army, according to their relative ranks.

The compliments above directed are to be paid by the troops, to officers in the ſervice of any power in alliance with his majeſty, according to their reſpective ranks.

Turning out of the line.—The line turns out without arms, whenever any part of the royal family, or the general commanding in chief, comes along the front of the camp.

When the line turns out, the private men are to be drawn up in a line with the colours and ſtandards ; the corporals on the right and left of their reſpective companies, the picquet forms behind the colours, accoutred, but without arms.

The officers and non-commiſſioned officers are to be drawn up with their reſpective companies. The field-officers in their proper poſts in battalion, two enſigns taking hold of the colours.

When the commander-in-chief comes along the line, the camp-colours on the flanks of the parade are to be ſtruck, and planted oppoſite to the bells of arms, and the drums piled up behind the colours ; the halberts are to be planted between, and on each ſide of the bells of arms, the hatchets turned from the colours. James.

HONOUR *Point*, in *Heraldry*, is that next above the centre of the eſcutcheon, dividing the upper part into two equal portions. See POINT and ESCUTCHEON.

HONOUR, *Abatements of.* See ABATEMENT.

HONOUR, *Additions of.* (See ADDITIONS.) Theſe additions are ſaid to be nine in number ; *viz.* a border, a quarter, a canton, a gyron, a pile, a flaſque, a flanche, a voider, and an eſcutcheon of pretence. (See each term reſpectively.) When additions of honour have been granted, faſhion alone ſeems to have guided the choice of the particular ordinary. In the reign of king Henry VIII., the pile had the preference ; and was granted by that king, as an augmentation of honour, to the lady Jane Seymour, and alſo to the lady Catharine Parr. But of late years, when the ſovereign grants an augmentation to the arms of a ſubject, it hath been uſual to place it either on a quarter, or on a canton. The eſtimation in which theſe ordinaries were anciently held, on account of their being occaſionally granted as additions of honour, hath been conſiderably diminiſhed, ſince it has been cuſtomary for any perſon of property, wanting and applying at the college for a coat of arms, not only to obtain a grant of arms, to him and his heirs, on paying the fees, but to have the figures of any of the additions of honour, in caſe he requeſts it, placed in the coat, although neither he nor any of his anceſtors ever had any particular merit to intitle him to marks of the royal favour.

HONOURABLE AMENDS, *Amende honorable.* See AMENDE.

HONOURABLE, or *Honourable ordinaries*, in *Heraldry.* See ORDINARY.

HONOURARY, or HONORARY, is underſtood of a perſon who bears or poſſeſſes ſome quality or title, only for the name's ſake, without doing any of the functions thereto belonging, or receiving any of the advantages thereof. See *Counſellors of* Honour.

In the College of Phyſicians, London, are honourary fellows. The Royal Academy of Sciences at Paris formerly conſiſted of four claſſes of members, viz. honourary, penſionary, aſſociates, and adjuncts. See Academy.

Honourary *Feuds*. See Fee and Descent.

Honourary *Games*. See Games.

Honourary *Services* are thoſe incident to the tenure of grand ſerjeantry, and commonly annexed to honours.

Honourary *Tutor* is a perſon of quality appointed to have an eye over the adminiſtration of the affairs of a minor, while the onerary tutors have the real effective management thereof.

Honourary, *Honorarium*, is alſo uſed ſubſtantively for a lawyer's fee, or a ſalary given to public profeſſors of any art or ſcience.

HONRUBIA, in *Geography*, a town of Spain, in New Caſtile; 10 miles N.W. of Alarcon.

HONSDORF, a town of Pruſſia, in the palatinate of Culm; 27 miles N.E. of Culm.

HONTAN, La, *Baron*, in *Biography*, was born in Gaſcogny, and ſerved in Canada, firſt as a ſoldier, then as an officer. From Canada, he was ſent to Newfoundland as king's lieutenant, where he quarrelled with the governor, and was caſhiered. He retired, firſt to Portugal, then to Denmark. As an author he is known by "Voyages dans l'Amerique Septentrionale," two volumes 12mo. in which we have an account of the different tribes inhabiting North America, their government, laws, cuſtoms, religion, &c.

HONTFONGENETHEF, a thief taken hond-habend, *i. e.* having the thing ſtolen in hand.

HONTHORST, Gerard, in *Biography*, was born at Utrecht in 1592, and was placed as a diſciple with Abraham Bloemart: but when he quitted that maſter, he travelled to Rome, and proceeded ſo happily in his ſtudies as to be accounted one of the beſt artiſts of his time. He continued at Rome for ſeveral years, being employed there by perſons of the firſt rank, and particularly by prince Juſtiniani, for whom he performed many conſiderable works.

His particular excellence was ſhewn in his night-pieces, repreſenting figures by candle-light, which uſually were as large as life. Even Rubens profeſſed himſelf an admirer of his paintings in that ſtyle; and Sandrart highly commends a picture of the Decollation of St. John by torch-light, which he ſaw at Rome, in the church of Madonna della Scala. He alſo mentions another in the Juſtiniani gallery, of which the ſubject is, Chriſt brought bound before Pilate, in a white robe; and in that compoſition, the light proceeding from the flambeau and torches produced ſo uncommon a luſtre, and ſo bold an effect, that no preceding artiſt had performed any thing in that ſtyle that could be compared with it. Sandrart alſo obſerves, that Honthorſt was as much diſtinguiſhed, while he reſided at Rome, for his night-pieces in large, as Elſheimer was for his manner of deſigning the ſame ſubjects in ſmall.

Soon after his returning to his own country he viſited London, and obtained the favour of king Charles I. by ſeveral grand performances and portraits; eſpecially by one allegorical picture, in which he repreſented the portraits of the king and queen, in the characters of two deities, and the portrait of the duke of Buckingham in the character of Mercury, introducing the liberal arts to that monarch and his conſort. For that compoſition, which was well drawn and extremely well coloured, the king preſented him with three thouſand florins, a ſervice of plate for twelve perſons, and a beautiful horſe; and he had afterwards the honour to inſtruct the queen of Bohemia, and the princeſſes her children, in drawing.

His pencil is free and firm, and his colouring hath a great deal of force, although it often is not pleaſing, by a predominancy of the yellow and brown tints; yet undoubtedly Honthorſt would have been an excellent painter, if he had known how to give more grace, and more correctneſs to his figures.

At his return from London to Holland, he adorned the pleaſure houſes of the prince of Orange with many poetical ſubjects, which he executed in freſco as well as in oil; but he principally was employed in painting portraits, which are deſcribed as having good expreſſion, and extraordinary life and force, by their broad maſſes of light being contraſted by ſtrong ſhadows. He died in 1660, aged 68.

Honthorst, William, brother to the preceding, was born at Utrecht in 1604, and learned the art of painting from Abraham Bloemart. The portraits which he painted were very much eſteemed, and in reality thoſe were his moſt commendable performances; for the hiſtorical ſubjects of his hand, which generally were painted in a large ſize, are in no degree equal to thoſe of Gerard, either in reſpect of the compoſition, the handling, or the colour, although they are frequently ſold for the works of that maſter. He died in 1683, aged 79.

HONTHY, or Honddy, in *Geography*, a river of South Wales, which runs into the Uſk, at Brecknock.

HONTORIA *de Valdecarados*, a town of Spain, in Old Caſtile; 22 miles W. of Oſma.

HOOBARREE, a town of Africa, in the country of Sahara; 320 miles S.W. of Moorzouk. N. lat. 27° 12'. E. long. 9° 25'.

HOOD. See Chaperoon and Cucullus.

Hood, in *Falconry*, is a piece of leather, wherewith the head of a hawk, falcon, or the like, is covered.

After ſealing or ſewing up the eyelids of a young hawk, ſhe is to be fitted with a large eaſy hood, which is to be taken off and put on very often, watching her two nights, and handling her frequently and gently about the head. When you perceive ſhe has no averſion to the hood, unſeal her in the evening by candle-light, continuing to handle, hood, and unhood her, as before, till at laſt ſhe takes no offence, but will patiently endure handling.

After unſealing, anoint with the finger and ſpittle the place where the ſealing thread is drawn through; then hood her, and hold her on your fiſt.

As ſoon as ſhe is well reclaimed, let her ſit upon a perch; but every night keep her on the fiſt three or four hours, ſtroaking, hooding, and unhooding, &c. And thus you may do in the day time, when ſhe hath learnt to feed eagerly and without fear.

Hood, on *Ship-board*, is a copper frame, made to go on the top of the chimney, and to ſhift as the wind does, that the ſmoke may always fly to leeward.

Hood is alſo a ſort of low wooden porch, placed over the ſtair-caſe or ladder, which leads into the ſteerage or apartments, where the crew generally reſide in a merchant-ſhip. The uſe of the hood is to admit air and light, and at the ſame time to prevent the rain from falling into the ſteerage. The wooden porch over the entrance or ſtair-caſe of the maſter's cabin is called *companion*.

Hood's *Bay*, in *Geography*, a harbour on the W. coaſt of Admiralty iſland, in Chatham ſtrait. N. lat. 57° 26'. E. long. 225° 36'.

Hood's *Iſland*, an iſland in the Southern Pacific ocean, the moſt northerly of the five Marqueſas iſlands, diſcovered by captain Cook in April 1774, and ſo called after the name of the young gentleman by whom it was firſt ſeen ; about 48 miles in circumference. It is called by the natives Tebooa. S. lat. 9° 26′. W. long. 138° 52′. See Marquesas.

Hoods, in *Rural Economy*, the names of the ſheaves which head or cover the ſhocks or ſtouks of corn.

Hood *Sheaves*, another term employed to ſignify the ſame.

HOODED *Milfoil*, in *Botany*. See Utricularia.

Hooded *Willow-herb*. See Scutellaria.

HOODERS, a term given to the hood ſheaves of corn hattocks in many diſtricts.

HOOF, Ungula, the horny part which covers the feet of divers animals, as horſes, bullocks, &c.

The hoof ſerves much the ſame purpoſes as the nails of ſome animals and the claws of others.

The hoof of a horſe ſurrounds the ſole and the coffin-bone. To be good, it ſhould be of a dark colour, ſomewhat ſhining, high, ſmooth, of a round ſhape, but a little larger below than above ; ſhort, that the horſe may tread more on the toe than on the heel ; and ſomewhat hollow within, having a narrow fruſh and broad heels.

The hoof ſhould not have circles, which are a ſign of its being brittle, and that the horſe, being often ſhod, has had his feet ſpoiled by the many pieces broke out of it. A white hoof alſo is commonly brittle.

To judge whether the hoof be good and ſtanch, lift up the foot, and conſider if it have a ſhoe forged purpoſely for it, and be very much pierced, and the holes made in the unuſual parts, as wanting horn enough to take hold by in thoſe places where the nails are commonly driven. Sometimes they are forced to pierce the ſhoes nigh the heels, becauſe the fore-part is bad ; it being unuſual to drive the nails near the heels, except the toe be ſo much ſplit and broke as not to bear nails.

If the hoof be not round, but broad, and ſpreading out at the ſides and quarters, the horſe commonly has narrow heels, and, in time, will be flat-footed ; which ſort of foot is weak, and will not carry a ſhoe, nor travel far, but ſurbate ; add, that treading more on his heels than his toes, will cauſe him to go low on his paſterns.

If the hoof be long, it will make him tread altogether on his heels. If crooked, *viz.* broad without and narrow within, ſo that the horſe is ſplay-footed, it will cauſe him to tread too much inward, and cut or interfere. If the fruſh be broad, the heels will be weak and ſoft. If the heel be narrow and tender, the horſe will in time grow hoof-bound.

This ſort of horny material, when ground or broken down in proper mills, has been found an extremely laſting manure, and capable of affording large crops. See Manure.

Hoof, *Bony*, is a round bony ſwelling, growing on the top of a horſe's hoof, which is always cauſed by ſome blow or bruiſe. This is firſt to be ripened and brought to ſuppuration by digeſting it with rotten litter, or hay boiled in ſtale urine, or with a plaſter of ſtale wine-lees and wheat-flour boiled together. When it is come to a head, let it be lanced with a thin hot iron, and put a tent into it made of turpentine, deer's fat, and wax, boiled together in equal quantities, and lay a plaſter of the ſame over the tent.

Hoof, *Brittle*, the name of an infirmity to which horſes are ſubject. It comes ſometimes naturally, and ſometimes artificially. When it comes naturally, it is generally hereditary, the ſire or dam having had the ſame complaint. When it comes on accidentally, it is ſometimes owing to a diſtemper falling down into the feet ; ſometimes to the creature's being much foundered.

The hoof, in this diſtemper, is ſo friable and rotten, as it were, that it cracks and flakes off on every ſlight occaſion. The cure is to be attempted in this manner : take wax, turpentine, ſuet, and hog's lard, of each four ounces ; ſallad oil, a quarter of a pint by meaſure ; and of dog's greaſe, half a pound ; let the whole be melted together, and ſtrained through a piece of canvas into a gallypot. The hoof is to be thoroughly anointed with this every day, morning and evening, eſpecially at the root ; and if there are any large cracks, they muſt be filled up at every dreſſing with a mixture of equal parts of cow-dung and hog's lard.

The other infirmities to which hoofs are liable, are, the caſting of the hoof, hoof-bound, hoof-hard, hoof-hurt, looſe hoof, falſe quarters, &c.

Hoof, *Caſting of the*. A horſe is ſaid to *caſt his hoof* when the whole coffin of the hoof becomes looſened, and falls off from the bone. This may be remedied by care, and proper application ; a new hoof being procurable, if the coffin bone, &c. be not hurt.

Horſes ſometimes caſt their hoofs, by reaſon of ſome prick, ſtub, foundering, ſurbating, or other accident, that cauſes an impoſtumation in the foot ; ſo that the hoof, and ſometimes the coffin bone, being ſpongy and eaſily broken, fall off in large pieces. The laſt, when it happens, is a deſperate caſe.

Hoof-*bound*, is a ſhrinking in of a horſe's hoof on the top and the heel, which makes the ſkin ſtare above the hoof, and grow over the ſame.

It befals a horſe divers ways, either by keeping him too dry in the ſtable, by ſtraight ſhoeing, or by ſome unnatural heat after foundering.

Hoof-*hurt*. In labouring beaſts, eſpecially oxen, if the hoof be hurt with a coulter or ſhare, it may be cured by a ſalve of pitch and greaſe mixed with powder of brimſtone, diſſolved together, and with a hot iron melted in the cleft of the hoof.

Hoof-*looſened*, is a diſſolution or dividing of the horn or coffin of a horſe's hoof from the fleſh, at the ſetting on of the coronet.

If the parting be round about the coronet, it comes by means of foundering ; if in part, then by a prick of ſome channel nail, quitter-bone, retreat, gravelling, cloying, or the like. The ſigns of being looſened by foundering, is its breaking firſt in the fore part of the coronet, right againſt the toes ; becauſe the humour always deſcends towards the toe. If it proceeds from pricking, gravelling, or the like, the hoof will looſen round about equally even at firſt. If occaſioned by a quitter-bone, or hurt on the coronet, it will break right above the grieved part, and rarely be ſeen to go any farther.

Hoof-*ſwelled*, is an infirmity that ſometimes befals young horſes, when they are over-rid or wrought hard, which makes them ſwell in that part, becauſe of the blood falling down and ſettling there ; which, if not ſpeedily removed, will uſually beget a wet ſpavin.

For the cure, take the ſtrongeſt aquafortis, and firſt file or draw away the old hoof to a conſiderable degree with a file or drawing iron ; then touch what is left of the hoof for three or four dreſſings with the aquafortis ; anoint the foot with an ointment made of one pound of hog's greaſe, three quarters of a pound of patch greaſe, five ounces of Venice turpentine, three ounces of new wax, and three ounces of ſallad oil, melted together over the fire : and thus a new hoof will be made to grow on the foot.

Hoofs, in *Comparative Anatomy*, are the hard and inſenſible

ſenſible envelopes of the laſt phalanges of the toes in certain quadrupeds. They differ from nails in their form, being blunt, and broader at their termination than any other part, and being continued under the baſe of the phalanx and for ſome way behind. A hoof, when removed from the foot, has commonly the appearance of an irregular hollow pyramid; the anterior and lateral portions of the hoof are analogous in compoſition and mode of growth to the nails or claws. They are made of hard denſe compact horn, grow chiefly from the upper edge, which correſponds to the root of the nail, and are moulded by fine thin laminæ, which run downwards in the direction of the feet. Theſe laminæ are extremely numerous, and are very remarkable in the feet of the large quadrupeds, as the elephant, rhinoceros, &c.; are open and diſtinct in the horſe, but are leſs marked in the ruminant or cloven-footed quadrupeds. The ſtructure of the laminæ is membranous, or rather membrano-ligamentous; they are ſupplied with numerous blood-veſſels and nerves, but appear to be rather leſs vaſcular and ſenſible, than the ſoft parts within the ſole or inferior portion of the hoof. The ſenſible laminæ are inſerted between correſponding horny laminæ, ſituated upon the internal ſurface of the anterior and lateral portions of the hoof, by which the ſurface of connection between the hoof and the foot is vaſtly extended: indeed, the union is ſo ſtrong between theſe parts, that the whole weight of the large quadrupeds may be entirely ſuſtained by it, as is proved by the operation of removing the horny ſole of the foot in horſes, and likewiſe by the ſole deſcending when the adheſion of the laminæ is deſtroyed. See *Veterinary* ANATOMY and FOOT.

The inferior and poſterior portion of the hoof is compoſed of a horny ſubſtance. but of a texture leſs firm and tough than the anterior and lateral parts. The ſurface by which it is produced is not in general laminated, but covered with villous proceſſes. Theſe are extremely vaſcular and ſenſible, and are analogous in ſituation and office to the villi of the cutis covering the extremities of the fingers and toes of the human ſubject, and of the digitated quadrupeds. It appears to be chiefly on the ſenſible ſole of the foot in hoofed quadrupeds that impreſſions of touch are made, and although the extremities of theſe animals are incapable of ſurrounding ſmall objects, and therefore cannot convey ſenſations of the figure or extent of foreign bodies, they are moſt admirably conſtructed to give the animal notice of the mere preſence or the degree of reſiſtance of external objects. The ſurface within the hoof is ſo acutely ſenſible, that ſlight impreſſions are felt by it, while, at the ſame time, by the interpoſition of a ſtrong elaſtic ſubſtance, it is defended from the pain or injury that would enſue from more conſiderable impulſe. Another uſe of the hoof is to protect the feet from the preſſure and friction ſuſtained in the exerciſe of walking or in ſtanding. This is particularly neceſſary in the large quadrupeds, whoſe weight and almoſt conſtant erect poſition would otherwiſe bruiſe and wear their feet: the hoofs, therefore, may be conſidered as a ſort of natural ſhoes, having the additional property of a continual growth to repair their waſte. The proceſs of reparation, however, is only in a proportion ſuited to the natural habits, ſituation, and mode of life of the animal, and hence the neceſſity of ſhoeing ſome quadrupeds, and of cutting away exuberances from the hoofs in others. See articles ANATOMY *of the Horſe*, and SHOEING.

In ſeveral quadrupeds there are hoofs formed which never touch the ground; theſe grow upon the extremities of the imperfect toes, or thoſe which do not enter into the compoſition of the foot of the animal, and furniſh a ſtriking example of the uniformity of nature, even where it cannot anſwer any purpoſe.

HOOGE, PETER DE, in *Biography*, was born about the year 1643, but neither his native city, nor the maſter of this painter, are aſcertained by any of the writers on this ſubject; but by his manner of painting, Deſcamps accounts him to have been one of the beſt diſciples of Berchem. However, he ſeemed to admire and imitate the manner of Mieris, Metzu, and Slingeland, although, in the finiſhing of his pictures he did not arrive at the perfection of thoſe great artiſts.

The heads and hands of his figures have ſometimes a degree of force ſcarcely unworthy of being compared to Vandyke; but his touch is more broad and free than either Metzu or Mieris, and he falls far ſhort of their exquiſite neatneſs. His pencil is light and firm; his deſign correct and in a good taſte, as if he had been inſtructed in ſome celebrated ſchool. His uſual ſubjects are converſations, in which the draperies of his figures are taken from the modes of the times; and as to his colouring, it is extremely good, natural, and ſtrong.

HOOGEVEEN, HENRY, a celebrated Dutch philologiſt, was born of parents in humble life at Leyden in 1712. He was ſent to ſchool at 10 years of age, when the ſeverity of the maſter ſeemed to extinguiſh all his capacity for learning; but under a ſecond tutor his powers expanded ſo rapidly, that at the age of 15 he was able to relieve his father from part of the expence of his education, by commencing a teacher of the lower claſſes. He after this followed the buſineſs of a ſchoolmaſter at different places, and at Delft he ended his days in 1794. The works of this grammarian are, 1. An edition of "Vigerus de Idiotiſmis Linguæ Græcæ," which has been frequently reprinted, the addition by Hoogeveen being reckoned very valuable: 2. Poems, Orations, and other occaſional Pieces: 3. "Doctrina Particularum Linguæ Græcæ," in two volumes 4to. 1769. This procured the author a very high reputation among all the votaries of Greek learning throughout Europe. An abridgment of it has been made by Schütz. Since the death of Hoogeveen a poſthumous work has been given to the world, entitled, "Dictionarium Analogicum Græcum." It was printed at the univerſity preſs of Cambridge. Gen. Biog.

HOOGLIDE, in *Geography*, a town of France, in the department of the Lys, and chief place of a canton, in the diſtrict of Ypres. The place contains 3529, and the canton 13,258 inhabitants, on a territory of 105 kiliometres, in five communes.

HOOGLY, a circar or province of Bengal, about 80 miles in length from N. to S. and 48 in its medial breadth, much interſected, and formed into numerous iſlands by branches of the Hoogly and ſeveral other rivers.—Alſo, a ſmall but ancient city of Bengal, on the ſame river with Calcutta, but on the oppoſite ſide, and about 26 miles above it. In the time of the Mahometan government, it was the "bunder" or port of the weſtern arm of the Ganges, where the cuſtoms or duties on merchandiſe were collected. The French, Dutch, Danes, and Portugueſe, have each of them had a town and factory on this part of the river, between Hoogly and Calcutta; and all within the extent of ten miles along the river. In 1757 this town was taken by the Britiſh, and vaſt quantities of ſalt and proviſions belonging to the nabob of Bengal burned and deſtroyed. N. lat. 25° 54′. E. long. 88° 29′.—Alſo, a river of Bengal, formed by the junction of the Coſſimbuzar and Jellinghy, the two weſternmoſt branches of the Ganges, which runs into Bengal bay. This is the port of Calcutta, and the only branch of the Ganges that is commonly navigated by ſhips. The Coſſimbuzar river is almoſt dry from October to May; and the Jellinghy river, (although a ſtream runs in it the whole year,) is in ſome years unnavigable during two or three of the drieſt months; ſo that the only ſubordinate branch of the Ganges, that is at all times navigable, is the Chundnah river, which ſeparates at Moddapour, and terminates in the Hooringotta. The Hoogly river, which is the moſt weſterly branch of the Ganges, has a much deeper outlet into the ſea than the principal branch. This may probably be owing to its precipitating a leſs quantity of mud than the other; the quantity of the Ganges water diſcharged here being leſs than in the other, in the proportion of one to ſix. From the difficulties that occur in navigating the entrance of the Hoogly river, many are led to ſuppoſe that the channels are ſhallow. The difficulties, however, ariſe from bringing the ſhips *acroſs* ſome of the ſand-banks, which project ſo far into the ſea, that the channels between them cannot eaſily be traced from without. Rennell's Mem.

HOOGSTRATEM, a town of France, in the department of the Two Nethes, and chief place of a canton, in the diſtrict of Turnhout; 15 miles N. of Herenthals. The place contains 1360, and the canton 7227 inhabitants, on a territory of 202½ kiliometres, in eight communes.

HOOK, in *Angling*, &c. See FISHING-*hook*.

HOOKS, in *Building*, &c. are of various ſorts; ſome of iron and others of braſs, *viz.* 1. Armour-hooks, which are generally of braſs, and are to lay up arms upon; as guns, muſkets, half-pikes, pikes, javelins, &c. 2. Caſement-hooks. 3. Chimney-hooks, which are made both of braſs and iron, and of different faſhions; their uſe is to ſet the tongs and fire-ſhovel againſt. 4. Curtain-hooks. 5. Hooks for doors, gates, &c. 6. Double line-hooks, large and ſmall. 7. Single line-hooks, large and ſmall. 8. Tenter-hooks, of various ſorts. See TENTER.

HOOKS *of a Ship*, are all thoſe forked timbers which are placed directly upon the keel, as well in her run as in her rake. See BREAST-*hooks*.

HOOK, *Boat*, in a *Ship*. See BOAT.

HOOKS, *Can*, thoſe which being made faſt to the end of a rope, with a nooſe (like that which brewers uſe to ſling or carry their barrels on), are made uſe of for ſlings. See CAN-*hook*.

HOOKS, *Foot*, in a *Ship*, the ſame with futtocks.

HOOK-*land*, or *Ope-land*, land ploughed and ſowed every year. Dict. Ruſt.

HOOKS, *Loof*, in a *Ship*, a tackle with two hooks; one to hitch into a cringle of the main or fore-ſail, in the bolt-rope at the leech of the ſail by the clew; and the other is to hitch into a ſtrap, which is ſpliced to the cheſs-tree.

Their uſe is to pull down the ſail, and ſuccour the tackles in a large ſail and ſtiff gale, that all ſtreſs may not bear upon the tack. It is alſo uſed when the tack is to be ſeized more ſecure, and to take off or put on a bonnet or drabler.

HOOK-*pins*, in *Architecture*, are taper iron pins, only with a hook-head, to pin the frame of a roof or floor together.

HOOKS, *Sheer*, in a *Ship*, hooks like ſickles fixed in the ends of the yard-arms, that if a ſhip under ſail come to board her, thoſe ſheers may cut her ſhrouds, and ſo ſpoil her tackling. But as thoſe ſheer-hooks are ſubject to break their own yards, and cut the ropes that come from the top-ſails, they are now very ſeldom uſed.

HOOKS, *Trill*. See TRILL-*hooks*.

HOOKS, *Draught*. See DRAUGHT-*hooks*.

HOOKAH, a pipe for ſmoaking, uſed in India and among the nations of the Eaſt; conſiſting of a glaſs-veſſel of a globular form, nearly filled with water, from which iſſue two tubes, one perpendicular, on which the tobacco is placed, and the other oblique from the ſide of the veſſel, to which the mouth is applied. The advantage of this conſtruction is, that the ſmoke, in paſſing through the water, is cooled and rendered more agreeable. In company this inſtrument is circulated from one to the other, but among perſons of ſuperior rank and refinement, each perſon has a hookah appropriate to himſelf, which is often made of ſilver and ſet with precious ſtones; the tube, which is applied to the mouth, is long and pliant, and on this account denominated the ſnake; and the veſſel through which the ſmoke paſſes is filled with roſe water, and thus receives ſome of the fragrant quality of that fluid. The preparation of the hookah is the peculiar province of one of the domeſtics, and the uſe of it is reckoned among the luxuries of the Eaſt.

HOOKE, NATHANIEL, in *Biography*, author of a Roman hiſtory, was a Roman Catholic by profeſſion, and much attached to the myſtical doctrines taught by Fenelon. Few biographical facts are known relating to this perſon. He is ſaid to have enjoyed the confidence and patronage of perſons diſtinguiſhed as well by their virtue as their rank. He appears to have loſt the property which he poſſeſſed in the fatal South-ſea bubble. Not long after, he was recommended to Sarah, ducheſs of Marlborough, as a proper perſon to aſſiſt in compiling the memoirs of her own life, for which literary ſervice ſhe preſented him with the magnificent ſum of five thouſand pounds. The book, entitled "An Account of the Conduct of the Ducheſs of Marlborough, from her firſt coming to Court to the Year 1710," was publiſhed in 1742, but ſhe quarrelled with Hooke ſoon after, on account, as ſhe affirmed, of his wiſh to convert her to popery. The great work of Mr. Hooke was "The Roman Hiſtory," from its earlieſt periods to the ſettlement of the empire under Octavius. It was publiſhed at firſt in 4 vols. 4to., but it has ſince been publiſhed in 8vo., and a new edition of it was given to the world a few weeks ſince in 11 vols. 8vo. Another work of this hiſtorian upon Roman affairs, was "Obſervations on Four Pieces upon the Roman Senate." He alſo publiſhed a tranſlation of "Ramſey's Travels of Cyrus." Gen. Biog.

HOOKE, ROBERT, an eminent mathematician, who flouriſhed in the 17th century, was born at Freſhwater, in the Iſle of Wight, where his father was miniſter, in the year 1635. The brightneſs of his parts led his parents to intend him for the church, but the weak ſtate of health of the child, and his being ſubject to almoſt perpetual head-ache, made them deſpair of rendering their ſon a ſcholar. The youth being, in a good meaſure, left to himſelf, and to the bent of his own genius, turned his attention to mechanics, and employed himſelf in making toys, ſome of which diſcovered much ingenuity. At length he made a clock in wood, that would perform all the motions, and mark out in a rough manner the hours of the day. He diſplayed a taſte likewiſe for drawing, and ſoon after the death of his father he was placed under the celebrated painter ſir Peter Lely. To the profeſſion of painting he could not apply himſelf on account of his health. He therefore was placed firſt in Weſtminſter ſchool, and afterwards was ſent to Oxford. In 1655 he had made ſuch progreſs in the ſciences, that he was elected a member of a philoſophical ſociety at Oxford, and became an aſſiſtant to the honourable Mr. Boyle, in his experiments and purſuits, to whom he was particularly uſeful in the conſtruction of the air-pump. He was, likewiſe, an adept in aſtronomy, and conſtructed ſome inſtruments well adapted to the making of obſervations. In 1662, Mr. Hooke was appointed curator of experiments for the Royal Society, which met at that period at Greſham college; he engaged to furniſh the members, at every time of their meeting, with two or three new experiments of his own, and to purſue ſuch others as they ſhould recommend to him. This buſineſs led him to make ſeveral important diſcoveries relating to the nature and properties of the air. In 1663, when the Royal Society was eſtabliſhed by charter, Mr. Hooke was nominated one of the members who were appointed on the firſt council. The repoſitory of the ſociety was committed to his care, and a gallery in the Greſham college was appointed for its reception. In the following year he was made profeſſor of mechanics to the Royal Society, by ſir John Cutler, with a ſalary of 50*l.* per annum ſettled upon him for life, and in the ſame year he read aſtronomical lectures at Greſham college. He publiſhed, in 1665, his "Micrographia, or ſome phyſiological Deſcriptions of minute Bodies, made by magnifying Glaſſes, &c." This work he dedicated to the king, who had been inſtrumental in founding the ſociety, and who had ſhewn himſelf friendly to experimental purſuits, for all which he is applauded by Mr. Hooke in terms approaching to fulſome flattery. The meetings of the ſociety being now diſcontinued on account of the ravages of the plague, Mr. Hooke, accompanied by other perſons, among whom was doctor, afterwards biſhop, Wilkins, and ſir W. Petty, retired to the ſeat of the earl of Berkeley, where they diligently purſued their experiments, an account of which they afterwards communicated to the Royal Society when its meetings were reſumed. After the fire of London in 1666, Mr. Hooke offered to the court of aldermen a plan for re-building the city, which, though not followed, led to his appointment to the office of one of the city ſurveyors, in which he acquired conſiderable property. We ſhall not enter into the diſputes and controverſies in which Mr. Hooke engaged, in ſome of which he ſhewed a temper unworthy of a true philoſopher. In 1673 he propoſed a "Theory of the Variation of the Compaſs," and in the following year he publiſhed "An Attempt to prove the Motion of the Earth from Obſervations;" his next publications were "A Deſcription of Helioſcopes, &c." and "Deſcriptions of ſome mechanical Improvements of Lamps and Water-poiſes, together with phyſical and mechanical Diſcoveries." Upon the death of Mr. Oldenburgh, Mr. Hooke was appointed to ſupply his place in the office of ſecretary to the Royal Society; this was only a temporary appointment, as the office was in a few months given to Mr. Nehemiah Grew. Mr. Hooke was not contented with the reputation which he had acquired, though conſiderable, but on the publication of ſir Iſaac Newton's Principia, he laid claim to that great man's diſcovery concerning the force and action of gravity, his pretenſions to which were moſt ſatisfactorily refuted. In 1691 he was employed in forming the plan of the hoſpital near Hoxton, which was founded by alderman Aſke, who appointed archbiſhop Tillotſon one of his executors, and in the ſame year Mr. Hooke was by that prelate created M. D. In 1696 the Royal Society would gladly have employed him in a repetition of his experiments at their expence, but his ill ſtate of health prevented him from engaging in the buſineſs. He died at his apartments in Greſham college in 1702, in the ſixty-eighth year of his age. Several of his papers may be ſeen in the Tranſactions of the Royal Society; and after his death, in 1705, his poſthumous works were publiſhed. He was a man of great mechanical genius, and the ſciences are indebted to him for ſeveral improvements, and for inſtruments adapted to the diſcovery of other new and uſeful facts. He was well acquainted with the ancient languages, and all the branches of the mathematics. He always maintained a great veneration for the Deity, and ſeldom received any ſignal benefit in life, or made any valuable diſcovery in nature, or invented any uſeful contrivance, or found out any conſiderable problem, without expreſſing his gratitude to Divine Providence. Biog. Brit.

HOOKER, JOHN, a learned antiquary, was born at Exeter in 1524, and educated at Oxford, after which he travelled into Germany. Upon his return he was elected a repreſentative in parliament for his native city in 1572. He wrote a deſcription of Exeter, and was author of ſome part of Holingſhed's Chronicle, beſides other pieces. He died in 1601.

HOOKER, RICHARD, nephew of the above, was born at Heavitree, near Exeter, in 1553; he was educated at the grammar ſchool of Exeter, from which place he was ſent to Corpus Chriſti college, Oxford, of which he was choſen fellow in 1577. He was indebted to the patronage of biſhop Jewel for a learned education, and calling once on the prelate in his way to Oxford, the biſhop gave him much good advice and his benediction, but forgot to give him any money; quickly, however, recollecting himſelf, he ſent his ſervant to call him back, and on his return he ſaid, "Richard, I have ſent for you to lend you a horſe, which hath carried me many a mile, and I thank God with much eaſe." He then gave him a walking ſtaff, with which he had himſelf travelled through many parts of Germany, and added, "Richard, I do not give but lend you my horſe; be ſure you be honeſt and bring my horſe back to me at your return from Oxford. I do now give you ten groats to bear your charges to Exeter (whither he was going to ſee his mother), and here are ten groats more, which I charge you to deliver to your mother, and tell her I ſend a biſhop's benediction with it, and beg the continuance of her prayers for me. And if you bring my horſe back to me, I will give you ten groats more to carry you on foot to the college, and ſo God bleſs you Richard." Shortly after this, young Hooker loſt his patron by the death of the good biſhop; he had, however, thoſe talents and that excellent diſpoſition which ſoon procured him other friends in Dr. Cole, then preſident in his college, and Dr. Edwin Sandys, biſhop of London, by whoſe intereſt he was elected ſcholar of his college in 1573. At the ſame moment almoſt, the biſhop placed his own ſon under the care of Mr. Hooker for college inſtruction, though he had not at that time attained to his twentieth year, but ſaid Dr. Sandys, "I will have for my ſon a tutor that may teach him learning by inſtruction, and virtue by example, and my greateſt care ſhall be the laſt." Mr. Hooker, while at college, was greatly diſtinguiſhed among his contemporaries, for the piety, regularity, and exemplarineſs of his life. In 1577 he took his degree of M. A., and was in the ſame year elected fellow of his college. In 1579 he was appointed deputy-profeſſor of the Hebrew tongue in the univerſity, and for a cauſe, not known, but which was probably of a very trifling nature, he and ſome others were expelled the college by the vice-preſident, to which they were again reſtored in the courſe of two or three weeks. Mr. Hooker took orders in 1581, and very ſhortly after was appointed to preach at St. Paul's Croſs in London. This appointment, which was eſteemed an high honour, produced a train of circumſtances, by which the young divine was, through the great ſimplicity of his character, entrapped into an unfortunate marriage with a woman who brought him neither beauty nor portion, and who has been repreſented as "a ſilly clowniſh woman, and withal a mere Xantippe." In conſequence of this ſtep Mr. Hooker loſt his fellowſhip, and was obliged to quit the univerſity before he had obtained any preferment. In 1584 he was preſented to the rectory of Drayton-Beauchamp, in Buckinghamſhire, where he lived a miſerable life with his ſpouſe. Here he was viſited by his friend and pupil Mr. Sandys in company with another pupil, Mr. Cranmer, a grand-nephew of the celebrated archbiſhop. The young man found their reſpected and very learned tutor tending a ſmall flock of ſheep, during the abſence of his ſervant, called away to perform ſome domeſtic employment. When he was releaſed from this duty, his friends accompanied him to the houſe, where they had the more ſerious mortification of witneſſing the churliſhneſs of a wife, who took every opportunity of rendering one of the beſt of men wretched by her caprice and vexatious manners. They felt for the ſituation of their friend, and Mr. Cranmer, before he left the houſe, expreſſed his ſurpriſe that he could poſſibly endure the miſeries and inſults to which he was ſubjected; to this Mr. Hooker replied, "My dear George, if ſaints have uſually a double ſhare in the miſeries of this life, I that am none, ought not to repine at what my wiſe Creator hath appointed for me, but labour (as indeed I do) to ſubmit mine to his will and poſſeſs my ſoul in peace." Upon the return of Mr. Sandys, he prevailed on his father to obtain ſome better ſituation for Mr. Hooker, and he was, accordingly, by his intereſt, made maſter of the Temple. He ſoon found that London was not adapted to his mind; he loved a rural retirement, in order, as he ſaid, "that he might ſee God's bleſſings ſpring out of the earth, and be free from noiſe and buſtle, and eat that bread, which he might call his own, in privacy and quietneſs." He was, therefore, deſirous of exchanging his preferment for a more retired and tranquil ſcene, and the more ſo, as he had begun and had made ſome progreſs in his celebrated work "Of the Laws of Eccleſiaſtical Polity," which he found himſelf incapable of carrying on to his own ſatisfaction in the Temple. Upon making known his wiſhes to archbiſhop Whitgift, and apprizing him of the undertaking on which he was employed, Mr. Hooker was preſented, in 1591, to the rectory of Boſcomb, in Wiltſhire; and in the ſame year he had other valuable preferments in the cathedral of Saliſbury. At Boſcomb he finiſhed four books of his great work, which were printed in 1594, and in the following year he was preſented by the queen to the rectory of Biſhop's Bourne, in Kent, where he reſided the remainder of his life, diſcharging the duties of his office in the moſt exemplary and conſcientious manner. Here he finiſhed his work, but he did not live to publiſh the ſixth, ſeventh, and eighth books. Of this very valuable piece pope Clement VIII. ſaid, "that there were in it ſuch ſeeds of eternity as will continue till the laſt fire ſhall devour all learning." In the year 1600, Mr. Hooker, in conſequence of a cold that he caught on a paſſage by water between London and Graveſend, was afflicted with a long and very ſevere illneſs, which, in the end, proved fatal to him. He died in November of the ſame year, when he was only in the forty-ſeventh year of his age. His treatiſe on "Eccleſiaſtical Polity," procured for him a very great and extenſive reputation both at home and abroad. When king James I. came out of Scotland, on his acceſſion to the throne of England, he enquired of archbiſhop Whitgift for his friend Mr. Hooker, and being anſwered that he had died before the queen, who received the news of his death with great regret, he replied, "And I receive it with no leſs, as I ſhall want the deſired happineſs of ſeeing and diſcourſing with that man from whoſe books of church polity I have received ſuch ſatisfaction. Indeed, my lord, I have received more ſatisfaction in reading a leaf or paragraph in Mr. Hooker, though it were but about the faſhion of churches, or church-muſic, or the like, but eſpecially of the ſacraments, than I have had in the reading particular large treatiſes but of one of thoſe ſubjects by others, though very learned men; and though many others write well, yet in the next age they will be forgotten; but, doubtleſs, there is in every page of Mr. Hooker's book the picture of a divine ſoul, ſuch pictures of truth and reaſon, and drawn in ſo ſacred colours, that they ſhall never fade, but give an immortal memory to the author." This work, ſo highly applauded by a pope, and a king, who conſidered himſelf much wiſer and more learned in theology than all the popes, contains the moſt profound and ableſt defence of eccleſiaſtical eſtabliſhments that has ever appeared. Biog. Brit. Toulmin's Neal.

Hooker is the name of a veſſel built like a pink, but rigged and maſted like a hoy; much uſed by the Dutch.

HOOKERIA, in *Botany*, ſo called by Dr. Smith, in honour of his friend Mr. William Jackſon Hooker, F.L.S. a moſt aſſiduous and intelligent botaniſt, celebrated as the diſcoverer of the *Buxbaumia aphylla* in England, and particularly ſkilled in the knowledge of cryptogamic plants, eſpecially *Jungermanniæ*, with the reticulated habit of which that of the *Hookeria* accords. The intereſting journal of a tour to Iceland, which Mr. Hooker has lately printed for the uſe of his friends, gives a foretaſte of what the world may expect from his labours in a more promiſing and more extenſive undertaking. Sm. Tr. of Linn. Soc. v. 9. 275.—Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Capſule ovate, with dot-like reticulations, from a lateral ſcaly ſheath. Outer fringe of ſixteen teeth; inner a ſixteen-toothed membrane. Veil reticulated and cellular, undivided.

Ten ſpecies are deſcribed in the Linnæan Tranſactions, four of which, not previouſly figured, are there engraved. The only Britiſh one is

H. *lucens*. Engl. Bot. t. 1902. (Hypnum lucens; Linn. Sp. Pl. 1589. Sm. Fl. Brit. 1295. Hedw. Fund. v. 1. 13. t. 1. f. 4—6. H. pennatum aquaticum lucens, longis latiſque foliis; Dill. Muſc. 270. t. 34. f. 10.)—Leaves three-ranked, elliptical, uniform, entire, without ribs.—Found in moiſt ſhady ſituations, in various parts of England, eſpecially in the northern counties, as well as in Germany and North America. Mr. Hooker gathered it on Holt heath, Norfolk, in wet places among graſs, bearing fruit in February. This is one of the moſt elegant of moſſes, diſtinguiſhed by its broad, pellucid, finely reticulated, ſucculent, pale green *leaves*, which ſtand upright, apparently in two rows, but moſtly diſpoſed in three; they ſometimes take root at their blunt points. *Sheaths* lateral, ſolitary or in pairs, of ſeveral ovate, pointed, ribleſs ſcales. *Fruit-ſtalks* ſolitary, erect, five times the length of the leaves, rather ſtout, deep red and ſhining, bulbous at the baſe. *Capſule* more or leſs drooping, ovate, ſhort, dark brown, ſhining, all over moſt beautifully and regularly marked with dot-like reticulations, which by a miſtake in the engraver of Engliſh Botany (for the drawing was correct), are repreſented like furrows only. Every other part of that plate, however, is correct. The ſingularly cellular white *veil*, which falls off entire, without ſplitting, is perhaps as good a mark of the genus as any. The *lid* is conical, as long as the capſule.

Among the exotic ſpecies the moſt remarkable for its hiſtory is

H. *pennata*. (Leſkea pennata; Labillard. Nov. Holl. v. 2. 106. t. 253. f. 1. Anictangium bulboſum; Hedw. Sp. Muſc. 43. t. 6. f. 1—5.)—Leaves three-ranked, ſomewhat pointed, finely ſerrated; the intermediate row orbicular, half the length of the reſt, which are lanceolate, and longer than the fruit-ſtalks.—Gathered by M. Labillardière, and Mr. R. Brown, in New Holland; at Duſky bay, New Zealand, by M. A. Menzies.—Larger than the foregoing, with creeping, denſely tufted, black *roots*. Hedwig miſtook them for bulbous ones, and ſeeing only half-ripe *capſules*,

ſules, did not detect the fringe, which cauſed him to refer this moſs to his *Anictangium*. Mr. Brown found its *veil* to agree with that of *H. lucens*, which confirms the character of the genus. The ſimple fern-like form of the ſtem and flat leaves is peculiarly elegant. The height of the plant is from three to five inches.

The eight remaining ſpecies of *Hookeria* are *quadrifaria*, Tr. of Lin. Soc. v. 9. t. 23. f. 1.; *filiculiformis*, Hedw. Sp. Muſc. t. 50; *tamariſcina*, ibid. t. 51. f. 1—7; *rotulata*, ibid. f. 8—13; *flabellata*, Tr. of Lin. Soc. v. 9. t. 23. f. 2; *Arbuſcula*, ibid. f. 3; *flexilis*, Hedw. Sp. Muſc. t. 58; and *uncinata*, Tr. of Lin. Soc. v. 9. t. 23. f. 4.

HOOKETOWER, in *Geography*, a cape on the ſouth of Ireland, at the extremity of a tongue of land in the county of Wexford, which forms the eaſtern ſide of Waterford harbour. On this cape is a light houſe. N. lat. 52° 6′. W. long. 6° 58′.

HOOLA, a town of Norway, in the dioceſe of Aggerhuus; 32 miles N.W. of Chriſtiania.

HOOLDEAH, a town of Bengal; 21 miles S. of Calcutta.

HOOLE, Charles, in *Biography*, who flouriſhed in the 17th century, was born at Wakefield, in Yorkſhire, and educated at Lincoln college, Oxford, after which he became maſter of the free-ſchool at Rotheram; but at the beginning of the civil wars he removed to London, where he gained great reputation as a ſchool-maſter. He was author of many uſeful ſchool books, an excellent edition of the Greek Teſtament, and a tranſlation of Terence's plays. He died in the year 1666.

Hoole, John, a very ingenious man, was born in London in 1727. His father was a watch-maker, and a very able mechanician. He gave his ſon a very good education, and obtained for him a clerkſhip in the India Houſe. During his engagements in this ſituation he devoted his leiſure hours to literary purſuits, particularly to the ſtudy of the Italian language, of which he acquired an extenſive and very deep knowledge, as appears by his tranſlations of Arioſto's Orlando Furioſo, and Taſſo's Jeruſalem. He alſo publiſhed two volumes of the dramas of Metaſtaſio, and was author of three tragedies, ſome poems, and the life of Mr. Scott of Amwell. He died in the year 1803.

HOOLI, the name of a cheerful feſtival, celebrating the arrival of the vernal equinox, as the "Duſſera," at the end of ſummer, is appropriate to the autumnal equinox. It is obſerved in honour of Narrain, or the favourite god Kriſhna, of the Hindoo mythology, who is the Apollo of the Hindoos, the god of dance and muſic, of pleaſure and of ſport. This feſtival takes place the firſt full-moon after the ſun has paſſed the vernal equinox, and is calculated to hail the approach of ſpring. Its ceremonies conſiſt entirely of the moſt frolickſome and playful ſports. All ranks and ages mix in its celebration; and among other acts, during its continuance, caſt at each other handfuls of a pulverized ſcarlet flower, the jubba (*ixora Linnæi*), and thin elaſtic balls, filled with a liquid coloured by the ſame plant; theſe burſt on the ſlighteſt reſiſtance, and cover the whole dreſs and perſon of him who is ſtruck by it with a crimſon ſtain. It is deemed no diſgrace on this occaſion to bear the moſt obvious traces of the deepeſt dye; for when once the barrier of the "Zennara" (the apartments of the females), is broken down, the ſovereign himſelf ſets aſide his high deſpotic character, and unbends in frolickſome feſtivity. Unreſtrained liberty of ſpeech and repartee prevails; and the females of every family particularly delight in giving free indulgence to theſe romping ſports, which are equally kept up by the Mahometans and the Hindoos. Turner's Tibet, p. 144, &c.

HOOLSOVRY, in *Geography*, a town of Hindooſtan, in Dowlatabad; 15 miles from Balkee.

HOOLY-ONORE, a town of Hindooſtan, in the Myſore country, ſituated at the conflux of the Toom and the Badra, where they form the Tungebadra; taken by the Britiſh troops in December, 1791; 56 miles N.W. of Seringapatam.

HOONGA-HAPAEE, and Hoonga-tonga, ſmall iſlands in the S. Pacific ocean, belonging to the group of Friendly iſlands; 30 miles N. of Tongataboo. S. lat. 20° 36′, and 10 or 11 leagues from the W. point of Annamooka. On the former five men reſide, and the latter is uninhabited. Both abound with ſea-fowl.

HOONLA, a town of Hindooſtan, in the circar of Cicacole; 11 miles W. of Ganjam.

HOOP, a town of Norway, in the government of Wardhuys; 76 miles W. of Wardhuys.

Hoop, in *Rural Economy*, a name frequently applied to a high ſort of cheeſe-vat, ſuch as that uſed in making Stilton and other kinds of ſmall rich cheeſes. See Cheese and Dairying.

Hoop, in *Agriculture*, the name of a dry meaſure of grain, which is equivalent to a peck, or a quarter of a buſhel. See Weights and Measures.

Hoop *Wheel*. See Detent-*wheel*.

HOOPER, Edmund, in *Biography*, organiſt of Weſtminſter Abbey, and a gentleman of the Chapel Royal, where he performed the duty of organiſt. He was one of the authors of the Pſalms in four parts, publiſhed in 1594, and of ſeveral anthems in Barnard's Collection. His full anthems and ſervices uſed to be performed in our provincial cathedrals within our own memory. He died July 14th, 1621.

Hooper, John, was born in Somerſetſhire in 1495, and educated in Merton college, Oxford. He was for ſome time a member of the order of Ciſtercians, but having imbibed the principles of the reformers, he quitted a monaſtic life, and went to Swiſſerland, where he was married. On the acceſſion of Edward VI. he returned to England, and was made biſhop of Glouceſter, to which was added the biſhopric of Worceſter in commendam. Here he laboured with great zeal till the reſtoration of popery under Mary. Biſhop Hooper was now thrown into priſon, whither the good old Latimer alſo was ſent ſoon after. Here he was exceedingly ill treated, underwent a mock trial, and was condemned to the flames through the means of the infamous Gardiner. Though tried at the ſame time with Rogers, who was burnt at Smithfield, he was ſent into his own dioceſe to be executed. This circumſtance was intended to ſtrike the greater terror into the breaſts of thoſe among whom he had laboured in the goſpel miniſtry, but it was to the biſhop a ſource of conſolation, who rejoiced in giving teſtimony, by his death, to the doctrine which he had formerly preached. When he was chained to the ſtake, a ſtool was ſet before him, on which was laid the queen's pardon if he would merit it by recanting his opinions. But he had made up his mind to the worſt that bigotry could inflict, and was prepared for the ſavage puniſhment to which he was ſentenced. He ſuffered it in its full ſeverity; the wood was green, and could not eaſily be kindled; his lower parts were literally conſumed before his vitals were attacked. One of his hands dropped off; with the other he continued to exhibit his fortitude and pious reſignation to the will of God. He was three quarters of an hour in torture, which he bore with inflexible conſtancy. This brutal act was perpetrated in the year 1555. Hume.

HOOPER, GEORGE, was born at Grimley, in Worceſterſhire, in the year 1640. He was educated at Weſtminſter ſchool, and from thence he was ſent to Chriſt's college, Oxford in 1656. Here he diſtinguiſhed himſelf by his talents and aſſiduous induſtry, and became very converſant in the knowledge of the mathematics and the ancient languages, including the oriental tongues, and particularly the Arabic. He took his degrees, and became chaplain firſt to Dr. Morley, biſhop of Wincheſter, and then to Dr. Sheldon, archbiſhop of Canterbury. He was ſhortly after preſented with the rectory of Lambeth, and the precentorſhip of Exeter. In 1677 he took his degree of D.D. and was ſent into Holland to attend the princeſs of Orange as her almoner. When he returned from the continent he was offered the profeſſorſhip of divinity at Oxford, which he declined, and in 1680 was appointed chaplain to the king. Little more is known of him from this time till 1691, excepting that he was commiſſioned by James II. to attend the duke of Monmouth in the Tower, on the evening before his execution. In the year already mentioned, during the abſence of king William in Holland, queen Mary, without any application on his part, promoted Dr. Hooper to the deanery of Canterbury. In 1701 he was choſen prolocutor to the lower houſe of Convocation, and was offered the primacy of Ireland by the earl of Rocheſter, then lord lieutenant. In 1702 Dr. Hooper was promoted to the biſhopric of St. Aſaph, in which ſee he continued only ſix months, when he was removed to the ſee of Bath and Wells. This change he very much objected to, and abſolutely refuſed farther promotion, though the biſhopric of London and the archbiſhopric of York were ſucceſſively offered him. It is ſaid of him that he conſidered himſelf as married to his dioceſe, and he uniformly promoted his own clergy to all the inſtances of preferment that fell into his diſpoſal. He regarded no intereſt, but made thoſe the objects of his favour who were moſt attentive to the duties of their ſituation. The care of his pariſh was the beſt recommendation of a paſtor to this vigilant prelate, and the continuance in his duty the moſt ſatisfactory requital that could be made him. Biſhop Hooper died at Barkley, in Somerſetſhire, in 1727, having preſided over his ſee nearly 25 years. He was author of a learned "Diſcourſe on Lent, in two Parts: the Firſt, an Hiſtorical Account of its Obſervation; and the Second, an Eſſay concerning its Original;" of "A Calculation of the Credibility of human Teſtimony," publiſhed in the "Philoſophical Tranſactions;" of "An Inquiry into the State of ancient Meaſures, with an Appendix concerning our old Engliſh Money;" and various other works. They were all collected and printed at Oxford in 1757, in one volume folio. Gen. Biog.

HOOPER, in *Ornithology*, a name by which ſeveral have called the cygnus ferus, or wild ſwan.

HOOPING COUGH, in *Medicine*. See PERTUSSIS.

HOOPOE, in *Ornithology*. See UPUPA.

HOORELL, in *Geography*, a town of Hindooſtan, in Mewat; 24 miles N. of Dig.

HOORINGOTTA, a river in Bengal, formed by the union of ſeveral others, which runs into the bay of Bengal, N. lat. 20° 50'. E. long. 90° 6'.

HOORN, a ſea-port town of Holland, ſituated on the Zuyder ſee. The town is fortified, as well as guarded by dams, has five gates, and contains ſome handſome buildings, churches, and hoſpitals. The adjacent land is very rich, and produces great quantities of butter and cheeſe, beſides fattening lean cattle, brought hither from the more northern parts of Europe; 11 miles E. of Alcmaer. N. lat. 52° 39'. E. long. 4° 54'.

HOORN, or *Horn*, a town of France, in the department of the Lower Meuſe, giving name to a ſmall county in the biſhopric of Liege; 3 miles W. of Ruremond.—Alſo, a ſmall iſland in a bay on the N. coaſt of New Guinea. S. lat. 3° 42'. E. long. 135° 42'.

HOORN *Iſlands*, two iſlands in the South Pacific ocean, diſcovered in 1616, by Le Maire and Schouten; each of which was governed by a king. The inhabitants are deſcribed as large and tall, ſtrong and well made, excellent runners and ſwimmers, of a yellowiſh brown complexion. Their hair was dreſſed in a ſingular manner, forming ſeveral tails, or erect, like hogs' briſtles. The different ranks ſeemed to be diſtinguiſhed by the number of theſe tails. Both men and women were naked, except a ſmall covering round the middle. The women were very deformed, having long breaſts that hung down below their ſtomachs like leather ſacks. Theſe people ſeemed to have no notion of a God or religious worſhip. S. lat. 15°. E. long. 171° 30'.

HOORN'S *Iſland*, a ſmall iſland at the E. entrance of the ſtraits of Sunda. S. lat. 5° 44'. E. long. 106° 24'.

HOORNBECK, JOHN, in *Biography*, a learned Dutch Proteſtant, was born at Haerlem in 1517. He was divinity profeſſor at Utrecht, and afterwards at Leyden, where he died in 1666. His application was very intenſe, and his learning various and ſolid. He underſtood many languages, both ancient and modern, as, the Latin, Greek, Hebrew, Chaldee, Syriac, Dutch, German, Engliſh, French, and Italian. He was author of very many works, which are enumerated by Bayle. He left two ſons, of whom one, Iſaac, was an eminent advocate at the Hague, and afterwards counſellor penſionary, keeper of the ſeals, and ſtadtholder of the fiefs of Holland and Weſt Frieſland. Bayle.

HOORNE, JOHN VAN, a diſtinguiſhed anatomiſt and phyſician, was born at Amſterdam in 1621. After the completion of his grammar education he was ſent to the univerſity of Utrecht for the purpoſe of entering on the ſtudy of medicine, and went through his courſe with honour. With a view to farther improvement he viſited Italy; but on his arrival in that country he entered the Venetian army, in which he ſerved for ſome time. Subſequently, however, his taſte for ſcience returned; and having ſtudied under the moſt eminent profeſſors of Italy he went to the univerſities of Baſil, Montpellier, and Orleans, in the firſt of which he received the degree of M.D. with ſome very honourable teſtimonies of his abilities. In conſequence of theſe he was appointed profeſſor of anatomy and ſurgery at Amſterdam ſoon after his return; and in 1653 he was made profeſſor of the ſame ſciences in the univerſity of Leyden, an appointment which he accepted with extreme pleaſure, and which he fulfilled with much celebrity until his death, in January, 1670.

Van Hoorne was a man of conſiderable literary attainments, being maſter of eight languages. His reputation with poſterity, however, reſts principally on his anatomical knowledge. He had great reputation as a teacher of anatomy, and ſeems to have been the firſt to deſcribe the thoracic duct in the human body, which Pecquet had already demonſtrated in other animals. He is ſaid to have been the firſt, likewiſe, to ſhew the intimate ſtructure of the teſtes. He drew a great number of anatomical figures, with great elegance, which were never publiſhed, but which, according to Haller, were in the library of the celebrated Boerhaave, at Leyden. Beſides having edited the works of Botallus, in 1660, and the book of Galen, "De Oſſibus," with the commentaries of Veſalius, Sylvius, &c. in 1665, Van Hoorne was the author of ſeveral works, almoſt entirely relating to anatomy, *viz.* "Exercitationes Anatomicæ I & II ad Obſervationes Fallopii anatomicas," &c. Liege, 1649, 4to.; "Novus ductus chyliferus, nunc primum delineatus, deſcriptus, et eruditorum examini propoſitus," ibid. 1652; "Microcoſmus, ſeu brevis manuductio ad hiſtoriam corporis humani in gratiam diſcipulorum," ibid. 1660, and ſeveral ſubſequent editions; "Microtechne, id eſt, breviſſima Chirurgiæ Methodus," ibid. 1663, 1668, Lipſiæ, 1675; "Prodromus Obſervationum ſuarum circa partes genitales in utroque ſexu," Leyden, 1668. This work was afterwards publiſhed by Swammerdam, who had made the greater part of the experiments there recorded, of which Van Hoorne only paid the expences. Swammerdam entitled it "Miraculum Naturæ," 1672, 4to.; "Obſervationes Anatomico-Medicæ," &c. Amſt. 1674, 12mo.; a poſthumous collection, under the title of "Opuſcula Anatomico-Chirurgica," was publiſhed by profeſſor Pauli, at Leipſic, 1707, 8vo. with annotations. Eloy. Dict. Hiſt.

HOOSACK, in *Geography*, a townſhip of America, in Renſſlaer county, New York, oppoſite Bennington, in Vermont, having 3141 inhabitants.

HOOSE, in *Rural Economy*, a term applied to an affection of the lungs, which is often met with in cows, pigs, and ſome other animals. In order to the removal of the complaint it has been lately adviſed to have recourſe to equal quantities of vinegar of ſquills and balſam of copaiva, as one ounce of each, adding double the ſame proportion of balſam of ſulphur, and four times as much honey, preparing it for one doſe, by means of a quart of penny-royal tea, and giving it to the beaſt immediately, which ſhould faſt two hours before, and as long afterwards. It ſhould be repeated every third day. Or, two ounces of powdered elecampane root, one each of ſalt of wormwood and powdered liquorice root, with the ſame quantity of the ſweet ſpirits of nitre, and half an ounce of ſulphurated quickſilver, may be given in the ſame way as above, and repeated every 24 hours.

While under theſe medicines, it is recommended that the beaſt ſhould be kept in the houſe, except in very fine weather, and when the graſs is quite dry. The drinking of cold water ſhould likewiſe be avoided.

HOOST, PETER CORNELIUS VAN, in *Biography*, was born at Amſterdam in 1581, of reſpectable parents, who gave him a good education. He attached himſelf to writing in his native language, and obtained the higheſt reputation both in poetry and hiſtory, ſo that his works were conſidered as a model of ſtyle. His principal piece was the Hiſtory of the Low Countries, commencing with the reſignation of Charles V. and reaching to 1588. This is much valued for the accuracy of its political and military ſtatements. It was firſt printed at Amſterdam in 1642, and has been ſeveral times reprinted. He was author alſo of a hiſtory of Henry IV. written in the Latin language; and in it is given a relation of the deſtiny of the houſe of Medici. His miſcellaneous works were printed in four volumes, conſiſting of epiſtles, comedies, and poems. Hooſt received the order of St. Michael from Lewis XIII. He died at the Hague in 1647. Moreri.

HOP, in *Botany*. See HUMULUS and LUMULUS.

We have but one ſpecies of this genus, which is diſtinguiſhed into the male and female hop.

The male hop grows wild by the ſide of hedges and upon banks, in many parts of England. The young ſhoots of theſe plants are often gathered by the poor people, and boiled as an eſculent herb; but theſe muſt be taken very young, otherwiſe they are tough and ſtringy. This is eaſily diſtinguiſhed by the flowers, which are ſmall, and hang in long looſe bunches from the ſide of the ſtalks, abounding with farina on their ſummits, and have no hops ſucceeding to the flowers.

Hops were firſt brought into England from the Netherlands in the year 1524. (15 Hen. VIII.) But they were known and uſed long before. They are firſt mentioned in the Engliſh ſtatute-book in the year 1552, *viz.* in the fifth and ſixth of Edw. VI. cap. 5. And by an act of parliament of the firſt year of king James I. anno 1603, cap. 18. it appears that hops were then produced in abundance in England.

HOP, in *Agriculture*, the name commonly given to a well known plant of the fibrous-rooted, perennial, climbing kind, which is chiefly grown for the uſe of the flower-bud, in affording an agreeable aromatic bitter to beer, and other ſorts of malt liquor. There is only one ſpecies of this uſeful plant in cultivation, but it has a number of varieties, which are made uſe of in different circumſtances and ſituations; ſuch as the *red* bind, the *green* bind, the *white* bind, and ſome others. The firſt of theſe affords but a very ſmall hop, yet, from its hardy qualities and habits of growth, it is capable of being employed with advantage in cold, expoſed ſituations, where the climate and ſoils are not ſo favourable as might be wiſhed, or improper for being planted with the other kinds. It is conſidered by many as reſiſting the *blaſt* more effectually than the other varieties, frequently ſhowing health and vigour where the other ſorts are greatly affected by the fly and the louſe, as well as leſs expoſed during the ſeaſon of picking to the injurious effects of the ſun and rain.

The green-bind variety, although much leſs hardy in its nature than the above ſort, is a much more productive bearer, and not unfrequently ſucceeds admirably in the medium deſcriptions of hop-ſoils, even where the expoſures are by no means the moſt favourable. The white-bind ſort, however, which is ſtill more tender and delicate in its habits, is in general held in the higheſt eſtimation by the hop planter, in conſequence of its being more early, and the produce of much higher value in the market.

Hops are likewiſe frequently diſtinguiſhed by the planters under the names of the Flemiſh, the Canterbury, the Goldings, the Farnham, and other ſimilar titles. The Flemiſh ſort is commonly ſuppoſed the moſt inferior in its qualities, being of the red-bind deſcription. It is the female hop-plant which affords the produce which is the object of the planter. Where the male plant is met with, it ſhould of courſe be removed, as of no utility.

As the different varieties of the hop become in a ſtate of maturity at different periods, and are proper for very different kinds of ſoil, the planter ſhould be careful that plants of the ſeveral ſorts be not intermixed, in ſetting them out, upon the ſame plantation or hop-ground; as where there is an inattention in this reſpect, it cauſes much trouble in the culture of the crop afterwards, eſpecially in extenſive concerns of this kind, on account of the ſcarcity of the labourers for getting on ſufficiently faſt with the neceſſary work.

But where the different ſorts are planted out in ſeparate plantations, this difficulty is wholly obviated, and the buſineſs of ſecuring and preſerving the crops rendered much more eaſy and convenient in its accompliſhment, by their becoming in a ſtate of maturity at different times.

Situations for Hop-grounds.—The moſt ſuitable ſituations and expoſures for the cultivation of hops are ſuch as ſlope gently to the ſouth, or which are level, and have a ſouth-weſterly expoſure, but which have the benefit of being protected from the effects of the north and north-eaſterly winds by ſome ſort of ſcreen or ſhelter, as thoſe of high grounds behind, &c. The plantations themſelves ſhould, however, be pretty free and open, as the plants riſe to conſiderable heights, and ſhould not be too much confined, but have a full circulation of air about them, and the perfect admiſſion of light, as well as the influence of the ſun, amongſt them; as, by ſuch means, the healthy vigour and growth of the binds may be not only promoted, but the too abundant moiſture that hangs upon them be ſpeedily diſſipated, and thereby the crops rendered leſs liable to be injured by the effects of the *blight* or *blaſt*, and the *mildew*, to all of which they are much expoſed. Situations contiguous to the ſea-coaſt, or in marſhy and fenny tracts that are level, are ſeldom ſuitable to the cultivation of the hop, as crops on them moſtly miſcarry in unfavourable ſeaſons for ſuch produce.

Soil and Preparation.—The ſorts of land which are the moſt proper for the growth of this kind of plant, are all thoſe of the more deep, ſtrong, friable, loamy, ſandy, or clayey deſcriptions. They ſhould have a diſpoſition to dryneſs, without being too deſtitute of a proper degree of moiſture, and be poſſeſſed of a good depth of mould of the rich vegetable kind. Soils of the thin, gravelly, and chalky ſorts are quite improper for the culture of this ſort of crop, as the former is not ſufficiently retentive of moiſture for the ſtrong, healthy growth of the plants, and the latter imparts its humidity too ſparingly to their fibrous roots, in conſequence of its great abſorbing quality.

Experience has, however, ſhewn that a thin, ſlaty ſoil, which reſts upon a ſub-ſoil of the ſtony kind, and which is greatly intermixed with rich mould, is well adapted to the hop culture, and affords equally full crops with thoſe of the rich deep kinds. The ſoil near Maidſtone, in Kent, on which hops are extenſively grown, is chiefly of this nature.

Such lands as have been long in the ſtate of paſture, and which of courſe are much intermixed with vegetable matter, as thoſe of old orchards, rich dry meadows, and other fertile paſture grounds, are in general the moſt proper for this uſe; but the hop may be grown on lands which have been under the plough, provided a ſufficient quantity of manure be employed to afford a proper degree of fertility for the due ſupport of the plants.

Whatever the ſtate of the land may be, on which this ſort of plant is grown, it ſhould be perfectly reduced and broken down into a fine ſtate of mould, to a conſiderable depth, by the repeated operations of the plough and harrow, or by being well trenched over by ſpade labour. The laſt is a very effectual method, where the land is to be broken up from the ſtate of ſward, though at preſent too expenſive, in moſt ſituations, to be employed; but wherever it is had recourſe to, the work ſhould be performed in the early part of autumn, in order that the grounds may have the full operation and influence of the froſts, during the winter, upon them. Theſe modes are both of them perfectly effectual in bringing hop-plantations into a fine ſtate of mould, and at the ſame time, in clearing them of every deſcription of weed that is injurious. During the concluding operations, where the plough method is practiſed, the land, if it be ſufficiently dry, ſhould be left in as regular and even a ſtate as poſſible upon the ſurface: but where it inclines to be wet, it is better to have it ridged up, as by that means the ſuperabundant moiſture may be in a great meaſure diſcharged.

In all caſes, juſt before the time of planting, a portion of compoſt, conſtituted of well rotted dung, and rich freſh vegetable mould, in the proportion of one of the former to two parts of the latter, well blended together for a conſiderable length of time, ſhould be applied in the holes where the hops are to grow, in the quantity of about a buſhel in each. This compoſt is uſually ſet out over the whole of the grounds firſt, and, after the holes have been formed, put into them.

The Sets and Methods of planting them out.—There are two ſorts of ſets occaſionally made uſe of in forming new hop-plantations, as thoſe made from the cuttings of the old binds, and root or bedded ſets, which are taken off from the vines in breaking up old hop-grounds. The firſt ſort is, however, moſt commonly made uſe of in the planting of new grounds, being formed in the early ſpring ſeaſon. The latter ſort is procured in the autumn from the old roots, in deſtroying former plantations. The cuttings ſhould be made from the beſt and moſt healthy plants, each being cut to the length of about five or ſix inches, leaving two or three eyes or joints in it, as the buds from which the new plants are to take their origin. It is uſual for them to be ſold by the hundred of ſix ſcore, at the rate of from ſixpence to a ſhilling.

The work of planting is executed at different ſeaſons, according to the kinds of plants or ſets which are employed. Where root ſets are made uſe of, the planting is generally performed in the autumn, about the end of October or the beginning of the following month, this being the period at which the former grounds are commonly dug up.

But where the cuttings of the binds are employed, the beſt ſeaſon of planting is uſually in the ſpring months, as from the end of February to the beginning of April, as the ſeaſon may be ſuitable; this being the time of cutting over and dreſſing the old binds, when the ſets can be moſt readily provided.

In the buſineſs of planting there are different forms and diſtances preferred by different planters, according to the method in which the culture of the crops is afterwards to be performed. In caſes where it is to be executed by means of horſe labour, which is the leaſt expenſive method, the beſt plan is that of ſetting them out in rows, at ſuitable diſtances, ſo as to form ſtraight lines in all the different directions. But where the work is to be done by means of hand-labour, this is not of ſo much importance, if proper care be taken to allow ſufficient ſpace for the perfect growth of the plants. Some, in this caſe, practiſe the row plan, while others have recourſe to what they call a triangular plan. It is plain, however, that the planting in rows at equal diſtances, in ſuch way as to admit of the ground between the plants being kept clean and in order by the harrow and nidget, muſt be far leſs expenſive than that of the irregular mode, in which hand labour can only be employed.

The different diſtances at which the holes and hills are formed, on which the plants are to be ſet out, vary greatly according to circumſtances. Some good planters recommend ſix feet and a half, or ſeven feet; while others are in the habit of giving preference to a five or ſix feet plant. In conſequence of plants of this ſort growing with great luxuriance and riſing to great heights, of courſe ſending forth much bind and foliage, they neceſſarily require a large ſpace, as where they ſtand too cloſely together, they are not only more apt to become infected with diſeaſe, but to *houſe* or twiſt together above the tops of the poles, by means of which, ſuch a degree of ſhade is given as prevents the hops below from completing their growth, and thereby leſſens the quantity of produce in the crop. For theſe reaſons it would appear, that the hop cannot be beneficially cultivated in a ſmaller ſpace than ſix or ſeven feet; on rich good ſoils the latter diſtance may be the more proper, but on others of inferior quality, the former.

There is a method of planting practiſed in ſome diſtricts on ſoils that are inclined to a moiſt boggy ſtate; which is that of forming the plantations in the bed-method, by digging them ſixteen feet in width, and taking out the trenches three feet in breadth, and from two to two and a half in depth, the earth which is removed being evenly ſpread out over the large previouſly prepared beds. On theſe, after the holes have been formed a ſpit in depth, twelve inches in diameter, and ſix feet diſtant in each direction, the ſets are put into the ſoil, in three rows on each large bed, in the manner that is uſual in other caſes.

Making the Holes and forming the Hills.—The holes for the reception of the manure are marked out in various modes, according to the particular practice of the diſtrict, and the taſte of the planter; with ſome it is the cuſtom to have recourſe to a line with knots formed in it, at the ſpaces which are intended for the holes; but others mark off at once the places for the holes, by driving ſhort ſtakes into the ground at proper diſtances in each direction. There is, however, a more expeditious mode of proceeding than either of the above ones, which is that of ſtriking furrows by the plough in different directions of the hop-grounds, at the neceſſary diſtances, in ſuch a way as to conſtitute a kind of ſquares, the holes being formed in the angles where the furrows croſs each other. Whichever method is followed, the holes are made by taking out the mould, to the depth of about twelve inches, by a ſpade, or, what is much better, by the tool termed a *ſpud*; always forming them in a circular manner, with the diameters of about eighteen inches; the bottom mould or ſoil being a little ſtirred or looſened at the time. Theſe holes are then to be filled partially with ſome of the compoſt already noticed, the mould that was taken out of them being replaced upon the compoſt, in ſuch a way as to form ſmall riſings or ſorts of hills. The ſets or roots are afterwards planted out upon theſe hills, to the number of ſeven upon each, by means of a proper dibbling ſtick, one being placed exactly in the middle or top of each of them, and the reſt at equal diſtances round it, at the diſtance of about four or five inches from the ſides of the holes. It is uſual to put the ſets or cuttings into the depth of about two inches in the compoſt, in ſuch a manner as to have the tops wholly covered by the mould on the ſurface part of the hills. It is thought better, however, by ſome planters, to have them covered lightly by the fine mould from the holes, after they have been planted out in the compoſt to nearly the above depth.

In ſetting out the plants on the large ridges, on the boggy ſorts of land juſt noticed, the work of holeing and hilling is commonly performed towards the latter end of July, or beginning of the following month.

After the buſineſs of holeing, hilling, and ſetting out the plants has been thus executed, nothing further is neceſſary to be done, until about the middle of May, except that of keeping the land about the plants well looſened, and perfectly clear from all ſorts of weeds, at which time, in conſequence of the growth of the young plants, it will be requiſite to apply an additional quantity of fine mould about them on the hills, which ſhould be ſcraped up from the intervals, with the view of checking the too luxuriant growth of the young ſhoots, and thereby promoting the vigour of the ſhoots; ſome likewiſe twiſt the ſhoots together into a kind of knot. Others, however, think it better to make uſe of two ſmall ſticks, about a couple of yards each in length, which are ſet firmly into each hill, ſo as to direct the climbing of the ſhoots, two or three, or more, being led up each ſtick, and occaſionally tied with baſs or ſedge during the ſummer ſeaſon. There will be a ſecond moulding neceſſary, in the ſame way, about the end of July, or beginning of the following month.

Where the planting is done on the boggy deſcriptions of land noticed above, the plants are poled in about three weeks with old ſhort poles, to each of which two or more of the binds are tied, the land being kept clean by hoeing and raking over occaſionally. This method is however more tedious and expenſive than the others, without much ſuperiority. By the whole proceſs the ground may probably be kept ſomewhat more dry and free from injurious moiſture.

Other ſorts of crops are by ſome grown along with thoſe of the hop kind, ſuch as thoſe of the common bean, French bean, cabbage, and onion kinds; but this is a practice that ſhould ſeldom be had recourſe to, as injury may be done by it to the hop-plants, by their affording too much ſhade, and thereby preventing the free admiſſion of air, light, and ſun to the young binds. Onions are the leaſt exceptionable ſort of crop for this purpoſe, in conſequence of their low growth, and their requiring to be ſown at the time the hop ſets are put into the ſoil. For the firſt year or two after the hops are put into the ſoil they may therefore be employed in ſome caſes with benefit. All ſorts of tall growing crops ſhould, however, be carefully avoided.

Hop-plantations, though they require ſome years to come to perfection, ſhould rarely, if ever, have any produce taken from them the firſt after they are formed, as by ſuch means great detriment is often done to the future produce which they ſhould afford. The Suffolk planters, in the mode of planting which they make uſe of, however, not unfrequently take a produce of from three to five hundred weight of hops, even the firſt year. Where bedded or root ſets are uſed in planting, a ſmall produce is even capable of being taken the firſt ſeaſon, as the plants or binds are nearly as forward at that period as thoſe from cuttings are in the ſecond.

In caſes where hop-grounds have been formed with care in theſe methods, and where the ſoils are well ſuited to the growth of the plants, they are capable of continuing in bearing for a great number of years, as twenty or more, the defects that take place in the hills being carefully ſupplied as they may occur. However, though this may be done, it is ſuggeſted as a better practice in moſt caſes to renew the plantations at conſiderably ſhorter diſtances of time, or to occaſionally renew certain portions as they may be found neceſſary and convenient. And, in all caſes, to render ſuch plantations as productive as poſſible, whether cultivated in the ſpade, plough, or hoe methods, the land in the intervals ſhould be well ſtirred two or three times in favourable periods, and in particular caſes more frequently.

It is rarely neceſſary, in the ſecond year of the plantations, to apply any manure to the hills; but the ground in the intervals ſhould be well looſened and ſtirred in the autumnal ſeaſon, in the ſame way as in the firſt year; however, in the early ſpring months, in ſuitable weather, as about the middle of March, the hills ſhould be opened, and the earthy mould well cleared away from the chief roots by a tool which is denominated a picker, in the view that the ſtocks may be properly pruned and dreſſed over; in which, all the bearing ſtems of the preceding year are cut off within a joint or two of the roots; and all ſuch ſhoots or ſuckers as were not permitted to be attached to the poles, or which have proceeded from the edges of the hills, completely cleared away, nothing being ſuffered to continue that can poſſibly injure or retard the healthy growth of the young plants or binds. Care ſhould be taken in the execution of this ſort of work, that the various ſtalks and roots be fully laid bare and open to ſuch a depth, that every thing that is prejudicial may be ſeen and eradicated. In the work of cutting over, experienced labourers ſhould conſtantly be employed as much as poſſible, as a great deal depends upon this ſort of work being properly executed, much injury being capable of being ſuſtained by the leaving too much length of bind, or by too cloſely cutting the ſtocks. By the former the crops are liable to be expoſed to *canker*; and by the latter, the hills to be ſo much weakened as not to afford ſhoots in ſufficient abundance. Conſequently, this ſort of work ſhould always be carefully overlooked. When the buſineſs of pruning and dreſſing has been finiſhed, the mould ſhould be raked and returned back again to the plants, ſo as to conſtitute as before a ſort of hills.

It is neceſſary likewiſe at this period that all ſuch plants as appear weak and unhealthy ſhould have others put in their places, that the hop-grounds may be kept quite perfect. Such prunings as are made from the moſt healthy and ſtrongeſt plants may be reſerved for being employed in forming new plantation grounds. And in this ſeaſon likewiſe, as well as the preceding, three hoeings and one *good* moulding up ſhould be given, the firſt at the beginning of May, the next about June, and the laſt in the ſucceeding month; a little fine mould being each time drawn up to the roots of the plants on the hills, ſo as to keep them in a properly moiſt ſituation. The mouldings up ſhould be performed about the beginning of Auguſt, the earth being well laid up over the hills, round the root-ſtems of the plants. It is the beſt done as ſoon as poſſible after rain has fallen.

Poling the Plants.—This is the next operation which becomes neceſſary, and the uſual rule in its execution is to begin the work as ſoon as the binds have ſprung up to the height of two or three inches above the ſurface of the land, which is uſually about the end of April or beginning of the following month. The moſt advantageous number of poles to each hill has not yet been fully aſcertained, but as a full and free admiſſion of air, light, and ſun is eſſential to the healthy growth of the plants, it ſhould evidently not be too great, ſo as to produce much cloſeneſs. Three are the moſt general allowance, though more are frequently made uſe of in the buſineſs. Theſe ſhould be placed in ſuch a manner as to leave the largeſt ſpaces or openings towards the ſouth or ſouth-weſt, in order that the plants may derive the more full influence of air, light, and heat, and thoſe which are the ſtrongeſt on the ſide towards the north, that they may the more effectually reſiſt the effects of winds from theſe quarters. The poles are fixed in the earth in general by means of a tool termed a crow, which is made of iron, and which forms the holes to the depth of eighteen or twenty inches, the ſharpened root ends of which being forced into them, the earth is afterwards immediately cloſed and rammed in about them. The chief difficulty of this buſineſs depends on pitching the holes to proper depths, on ſetting the poles down with ſuch force as that they may be firmly fixed at the bottoms, and on their upper parts having a direction outwards ſo as to prevent the houſing of the binds above them. If theſe objects be not attended to, there may be great loſs from the deſtruction of the plants. After the poles are ſet down, two or three binds may be trained up, each of them being tied in the manner already noticed in ſeveral places, by labourers accuſtomed to the work, and repeated as there may be occaſion. In caſes where the poles are tall, and the binds ſtrong, ſtanding-ladders may be neceſſary in executing the work near the tops of the poles.

It is found that this buſineſs requires particular regard in the early part of the ſummer. When the binds prove unexpectedly ſtrong and vigorous in their growth, and the hills have been polled with ſhort ſlender poles, it may occaſionally repay the trouble and expence, to have them repolled with thoſe of taller and ſtronger kinds, and the ſhort ones removed. In ſome inſtances great advantage has been gained in this way.

In the more early growth of the plants, the ſuperfluous binds of every ſort ſhould be repeatedly removed during the ſummer ſeaſon, as they ſhow themſelves, merely reſerving one or two on each hill, to ſupply the ſituations of ſuch as may have been injured in their firſt training to the poles, as ſuch accidents not unfrequently occur, from the tender buds being bruiſed or twiſted off by the great agitation cauſed by the action of the winds and other cauſes. Theſe are the whole of the neceſſary operations in the culture of the hop, previouſly to the ſeaſon at which the produce becomes ripe and ready for the hop-picker, which is known by the fragrant ſmell that is emitted from them, and their becoming firm, and of a brown colour. This uſually takes place about the middle of September, but ſometimes earlier.

Picking the Hops.—This is a buſineſs that requires much care and attention to ſee that every thing proceeds with propriety and diſpatch, as there is conſtantly much danger to be apprehended from delay, the crops being equally expoſed to miſchief from the effects of the winds as thoſe of continued rains. Preparatory to this work it is neceſſary to have proper baſkets, and bins or cribs in readineſs, and ſufficient in number to the extent of hop-ground and pickers which it may be requiſite to employ. Theſe things being in due order, the hop binds are cut over cloſe to the ſurface of the ground by perſons uſed to the buſineſs, and the poles drawn up; and then placed upon the frame of the bins with the binds upon them, generally to the number of two or three, in order to the hops being picked from them. It is common to employ three or four pickers, or more, on each ſide of a frame, for clearing the hops from the binds, which, with the perſon whoſe buſineſs it is to ſort the poles, are termed a ſet. But ſeveral ſets are engaged in the ſame grounds, where they are large. And it is not unfrequent to employ women and children in this ſort of work. When carefully ſeparated from the binds and leaves, the hops are dropt into cloths hung upon tenter hooks underneath, within the frame. As ſoon as this is filled, the hops are removed into a large ſack, in order to their being taken home to be dried on a kiln for the purpoſe. It is conſtantly neceſſary that this ſhould be performed as quickly as poſſible after the picking is done, that the hops may not ſuſtain any damage by continuing together in their damp or moiſt green condition; as where this is the caſe, they are frequently liable, particularly in warm ſeaſons, to be much hurt both in colour and flavour, even in a few hours, by the ſlight fermentation which comes on. The kiln is of courſe kept conſtantly in readineſs, and at work day and night during the picking ſeaſon. The pickers ſhould conſequently be well proportioned to the quantity of hops that can be dried off. Where the hops are ſuffered to accumulate, they ſhould be put in ſmall parcels looſely placed together. See HOP-*baſket*, HOP-*bin*, HOP-*crib*, and OAST.

Where crops of this ſort are tolerably full, a good picker will ſeparate from eight to ten buſhels of hops from the binds in the courſe of the day, which after being ſtoved or dried, moſtly weigh about one hundred weight. It is not unfrequent to let the picking of hops, in ſome places, by the buſhel, at prices varying according to the caſe, or difficulty of providing labourers. It will be neceſſary to have from ſixteen to twenty expert pickers, in favourable ſeaſons, where the produce is good, and where the oaſt is capable of drying off about eighty buſhels at each meaſuring. In addition to the pole puller and pickers it will be neceſſary to have another perſon in the plantation, in order to pick up the ſcattered and ſtraggling branches of the binds, and convey the hops to the oaſt or kiln. For this purpoſe a boy is ſufficient, who, from the nature of his employment, is uſually denominated the poke-boy. Horſe or hand labour is employed in the conveyance of the hops, according to the diſtance from the kiln. The dryer ſhould be perfectly ſteady and regular, and have a full knowledge of the buſineſs, as the profits of the planter greatly depend upon it; but the hop-grower ſhould never be inattentive to theſe matters himſelf. The wages of the different people who are engaged in theſe operations vary much in different places, according to particular circumſtances, but the Kentiſh hop-farmers formerly paid the pole pullers from eighteen pence to two ſhillings the day, with ſmall beer, the dryers half-a-crown, with an unlimited allowance of beer and ſpirits, and the pickers from three half-pence to two-pence the buſhel, with allowances of ſpirits, &c.; but theſe prices are pretty nearly doubled at preſent.

After the buſineſs of drying has been executed, the hops are taken away from the kiln by a ſhovel, and put in a room cloſe at hand, formed for the purpoſe, and termed the ſtowage-room. Here they are kept for five, ſix, or a greater number of days, as there may be occaſion, before they are become in a ſtate proper for being put in the bags; as, when bagged too ſoon, they are brittle, and neither draw ſo good a ſample, or weigh ſo heavy, as is otherwiſe the caſe. The beſt criterion is for them to remain until they have attained a tolerable degree of toughneſs, which is readily known by the feel. See OAST.

Bagging the Hops.—In order to render the bagging of hops eaſy and convenient, a round hole or trap is cut out and formed in the floor of the ſtowage room, exactly equal in dimenſions to that of the mouth of the bag, on which a frame of wood is faſtened, to which the edges of the opening of the bag are ſecurely fixed quite round. Then in each of the lower corners of the bag a ſmall handful of hops is firmly tied, when it is let fall through the hole to below, and the perſon termed the packer places himſelf in it, and by means of a heavy weight which he keeps conſtantly moving round in the places where he is not treading, preſſes and forces the hops down in a very cloſe manner into the bags, as faſt as they are thrown into them, in ſmall quantities at a time, by another labourer. The work proceeds in this way until the bag is quite full, when each of the upper corners have a few hops tied in them in the ſame manner as thoſe at the bottom, which ſerve as handles for removing them by. The bag is then taken up, and its mouth properly ſecured, after being taken from the frame. The cloſer the hops can be ſtowed into the bags, the better they keep both in their colour, ſmell, and taſte. Some loſs in the weight conſtantly takes place in the operations of drying, ſtowing, and rendering the hops proper for being bagged; it being the opinion of ſome that ſixty buſhels of well ripened freſh gathered hops, that have not been infeſted with the fly, will not, when dried and bagged, produce more than about one hundred weight. See HOP-*bag*.

Sample.—The goodneſs of ſamples of hops depends upon ſeveral different circumſtances, but principally on the clammy feel of the yellow farinaceous powdery matter which is ſprinkled over them, and their colour; the former of which, in the language of the hop planter and dealer, is termed the condition, and the ſample conſidered the more or leſs valuable by thoſe who are purchaſers, the more or leſs clammy it is in its feel; while it is of the greateſt conſequence in relation to the latter, that it ſhould be preſerved as bright as poſſible; yet it does not always follow that the brighteſt ſamples are the ſtrongeſt in their flavour. Theſe properties are likewiſe the cauſe of the planters making a diſtinction in the bagging of the hops, as well as in the ſtuff in which it is performed. See HOP-*bag*.

Stacking the Poles.—As ſoon as the picking and other operations have been executed, the poles ſhould conſtantly be collected together, cleared from the binds that may be upon them, and ſet up in proper ſtacks; if the work has not been done already, while the buſineſs of picking was going on. The poles are liable to be much damaged by remaining on the ground when ſurrounded with bind. This ſort of work is often done by the acre, which is probably the beſt method. The old ſhort improper poles are at this time ſeparated and reſerved for the new plantations, ſo that the planter is enabled to aſcertain the quantity of new poles that will be wanted for the next ſeaſon, which it is highly advantageous to have provided and prepared during the leiſure of the winter months. It is the cuſtom to ſhave the bark from all the ſorts of poles, except thoſe of the aſh kind, in which it ſeparates naturally the ſecond ſeaſon, that they may not be deſtroyed by the lodging of the worm in them. See HOP-*pole*.

Clearing away the Bind.—Immediately after the buſineſs of ſtripping and ſtacking the poles has been completed, the bind ſhould be cleared away, which in ſome places is done by tying it up into faggots, bavins, or ſmall bundles, when in a perfectly dry ſtate, being then either ſtacked up or placed in ſheds or other ſituations, in order to be uſed as fuel in ovens or other ways. The work is uſually executed at the rate of about ſixpence the hundred. Some planters however burn it upon the land, while others again permit it to be taken away by the labourers, for their own uſe. But the firſt is the beſt method. Whatever mode is in uſe, it ſhould not be neglected to be removed from the ground as ſpeedily as poſſible, in order that it may not interfere with the future culture of the plantations, ſuch as the winter diggings of it, the applications of manure of the compoſt kinds, and the taking up of the old ſtocks of the plants when they become in a declining ſtate.

Produce.—Hop crops vary more than moſt other ſorts in the quantity of produce, being capable of affording, under different ſtates of ſoils and ſeaſons, from two hundred to more than twenty hundred weight per acre. Upon the middling deſcriptions of ſoil, in pretty favourable years, it may be reckoned from ſix to eight or nine hundred weight, from ten to fourteen being moſtly ſuppoſed good crops. So large a produce as twenty hundred weight but rarely happens, and cannot be much expected by the planter.

Expences of cultivating Hop Crops.—In the county of Kent, the price that was formerly paid for the ſeveral different operations that become neceſſary in their culture, ſuch as hilling, winter digging, cutting, preparing poles, poling, tying, nidgeting, hoeing, picking and ſtripping, and ſtacking the poles, was about 4*l.* 11*s.* 4*d.* per acre. And the whole of the annual expence, ſuppoſing the growth to be ten hundred weight per acre, and the different operations executed at ſtipulated prices, by known neighbouring workmen who can be depended upon, to be 28*l.* 12*s.* 6*d.* including the undertaker for overlooking the plantation, who pays the workmen for the different operations, picking, drying, duty, rent, poles, manure, tythe, bagging, and nidgeting.

But where the planter pays the ſeveral labourers himſelf, the expences will amount to 29*l.* 11*s.* 4*d.* which leaves a profit of 19*s.* 4*d.* in favour of the former method of having the work performed.

Theſe expences at preſent ſtand a great deal higher, perhaps nearly one-half.

In the Hints to Gentlemen Farmers, the expences and profits of cultivating hops are ſtated in this way.

Expences per Acre.

	£.	*s.*	*d.*
Medium price of hop land, per acre, -	1	10	0
Digging the ground - - -	0	13	0
Dreſſing and pruning - - -	0	8	0
Poling - - - -	0	15	0
Hoeing three times - - -	0	9	0
Moulding once - - -	0	3	6
Tying binds to poles - - -	0	12	0
Stripping binds from poles - -	0	3	0
Stacking poles - - -	0	4	0
Sharpening poles - - -	0	10	10
Manuring - - -	2	0	0
Picking, drying, and duty, at 1*l.* 10*s.* 0*d.* the hundred, crop ſuppoſed 12 cwt. the acre. - -	18	0	0
Bagging, with occaſional expence of new bags, about - - -	0	16	0
Aſh poles, eſtimated at 30,250 the acre, and ſuppoſed to laſt eight years, medium price 18*s.* the 100 at the ſtub, the eighth part of which is nearly -	3	13	0
Carriage of them - - -	1	5	0
	£31	2	4

Theſe expences have ſince increaſed in a very great degree, probably not much leſs than one half.

Produce per Acre.

	£.	*s.*	*d.*
Suppoſing 1,200 cwt. per acre, and the medium price 4*l.* per cwt. the amount will be - - -	48	0	0
The expence deducted from the produce leaves a medium profit of - -	16	17	8

The profit, from the expences being lately ſo much augmented, muſt now be placed much higher.

The expence of forming new hop grounds is commonly very great, in many diſtricts being found to be not leſs than from ſixty or ſeventy, to one hundred pounds the acre. In ſome caſes they now ſtand much higher.

The moſt favourable ſeaſons for the growth of this ſort of crops in the whole of their different ſtages, are ſuch as are warm without too much wet, and where the ſouth and ſouth-weſterly winds predominate, as they never anſwer well where there is continued wet weather, or when northerly or eaſterly winds prevail for any length of time in the ſummer ſeaſon. Other cauſes of great injury to theſe crops are likewiſe found in hot gleams of ſun-ſhine after falls of rain, or ſucceeding foggy mornings in the more late ſummer months. Great miſchief is alſo produced by high winds towards the time of picking, in conſequence of the hops being much bruiſed and otherwiſe injured. The produce of ſuch crops is rarely either good or abundant, where unſuitable weather occurs about the time the hops are in bloſſom, as a number of the *bars* never become perfect hops. Forward and luxuriant crops almoſt invariably ſuffer more from all the hurtful cauſes which affect the hop plant, than ſuch as are later and of leſs ſtrong growth. It may conſequently be very uſeful in particular expoſed ſituations to remove all the more forward binds.

To aſcertain the duty of this ſort of produce, it is neceſſary for the planter to be in poſſeſſion of the different acts concerning it. However, every grower of hops is bound to give notice, on or before the firſt day of September, of the number of acres he has in this ſort of cultivation; the number and ſituation of his oaſts; and the place or places of bagging; which together with the ſtore rooms, warehouſes, &c. in which the packages are deſigned to be lodged are entered. And no hops can be removed from the rooms ſo entered until they have been weighed and marked by the proper officer; who marks, or ought to mark, on each package not only the weight, but the name and reſidence of the perſon by whom the hops are grown.

It may be noticed that the original duty was a penny on every pound weight, but the percentages that have ſince been added have raiſed it to about twenty-four ſhillings a bag, or thirteen ſhillings and fourpence the pocket, which is nearly ten pounds the ton. Theſe were the duties in 1790, but they have ſince that time been ſtill further increaſed in a high degree. This large duty is uſually paid to the collector of the exciſe for the particular diſtrict, and the grower has ſix months credit given him.

Hop crops are upon the whole both expenſive and uncertain, and the cultivation of which ſhould be well weighed before it is began. Where the ſoils are quite ſuitable for them; and there are poles ready at hand upon the land, with a ſufficient capital in the pocket of the planter, the hop culture is perhaps a kind of huſbandry that may be practiſed with benefit; but under other circumſtances it will ſeldom be found profitable. Where hops are grown in connection with a farm, it is neceſſary to attend to the extent of land that can be manured without injury being done to the other grounds under tillage huſbandry.

There are few field crops more expoſed to injurious affections than that of the hop. In its more early growth it is liable to the ravages of an inſect of the *flea* kind, juſt as it proceeds from the ſurface of the ſoil. When at a more advanced ſtage of its growth, it is expoſed to the more deſtructive attacks of the *green long-winged fly*, the *red ſpider*, and the *otter moth*. Lice are produced in large quantities by the former, in conſequence of their depoſiting their *ova* about the bottom parts of the plants, by which they are not unfrequently in a great meaſure deſtroyed; while the *larvæ* of the latter prey upon the roots from which the plants become weakly in their growth, and unhealthy. About the ſame time the *honey dew* is another morbid ſtate to which the hop-plant is expoſed, and by which it frequently ſuffers greatly. The *mould* or *fen* generally takes place at a rather later period, but is not leſs prejudicial in its attacks. The *blight* and *fire-blaſt*, to which hop crops are likewiſe ſubject, occur at different periods, but commonly towards the more late ſtages of the growth of the crops. All theſe different cauſes are extremely detrimental to the hop-planter, frequently proving ſuddenly deſtructive to his moſt promiſing crops. See Blast and Light, Flea, Honey-*dew*, Long-winged Fly, Mould, Mildew, Red Spider, and Otter-Moth.

Hops, *Diſeaſes of.* See Fire-blast, Fen, Honey-*Dew*, &c.

Hops, *Uſe of.* In the ſpring time, while the bud is yet tender, the tops of the plant being cut off, and boiled, are eaten like aſparagus, and found very wholeſome and effectual to looſen the body; the heads and tendrils are good to purify the blood in the ſcurvy, and moſt cutaneous diſeaſes; decoctions of the flowers, and ſyrups thereof, are of uſe againſt peſtilential fevers; juleps and apozems are alſo prepared with hops, for hypochondriacal and hyſterical affections, and to promote the menſes.

Extract of hops, *extractum humuli*, is made by boiling down half a pound of hops in a gallon of boiling water to four pints, ſtraining the hot liquor, and evaporating it to a proper conſiſtence. It is introduced into the London Pharmacopœia, becauſe it is ſuppoſed to poſſeſs both a tonic and ſedative power combined.

A pillow ſtuffed with hops, and laid under the head, is ſaid to procure ſleep in fevers, attended with a delirium. But the principal uſe of hops is in the brewery, for the preſervation of malt liquors; which by the ſuperaddition of this balſamic, aperient, and diuretic bitter, become leſs viſcid, leſs apt to turn ſour, more detergent, more diſpoſed to paſs off by urine, and in general more ſalubrious. They are ſaid to contain an agreeable odorous principle, which promotes the vinous fermentation. When ſlightly boiled or infuſed in warm water, they increaſe its ſpirituoſity.

Hops, *Laws relating to.* By 43 Geo. III. c. 68. for every hundred weight of hops imported, ſhall be paid a duty of 3*l.* 5*s.*; and on exportation there ſhall be allowed a drawback of 4*l.* 4*s.*; and for every pound of Iriſh hops imported a duty of 2½*d.* (43 Geo. III. c. 69.) And foreign hops, landed before entry and payment of duty, or without warrant for landing, ſhall be forfeited and burnt; the ſhip alſo ſhall be forfeited, and the perſon concerned in importing or landing ſhall forfeit 5*l.* a hundred weight. (7 Geo. II. cap. 19.) Hops of Britiſh growth may be exported to Ireland; bond being firſt given to the commiſſioners of exciſe, that the ſaid hops ſhall not be relanded, and oath made before ſuch perſon as they ſhall appoint, that the duties have been duly charged; upon which the perſon exporting the ſame ſhall have a drawback of the duties before paid; and provided that ſuch hops ſhall be relanded, or put into any ſhip in Great Britain (except in caſe of ſhipwreck, or unavoidable accident), the ſame, or the value thereof, ſhall be forfeited, over and above the penalty of ſuch bond; and may be ſeized by any officer of the cuſtoms or exciſe. (26 Geo. III. c. 5.) And for every hundred weight of hops, grown in Great Britain, which ſhall be cured, and made fit for uſe, ſhall be paid by the owner or poſſeſſor thereof, a duty of 2½*d.* (43 Geo. III. c. 69.) By 9 Anne, cap. 12. hop-grounds are required to be entered, on pain of 40*s.* an acre. Places of curing and keeping are alſo to be entered, on pain of 50*l.* which may be viſited by an officer at any time without obſtruction, under the penalty of 20*l.* All hops ſhall, within ſix weeks after gathering, be brought to ſuch places to be cured and bagged, on pain of 5*s.* a pound. The rebagging of foreign hops in Britiſh bagging for ſale or exportation, incurs a forfeiture of 10*l.* a hundred weight; and defrauding the king of his duty by uſing twice or oftener the ſame bag, with the officer's mark upon it, is liable to a penalty of 40*l.* The removal of hops before they have been cured, bagged, and weighed, and the duties aſcertained, incurs a penalty of 50*l.* Concealment of hops ſubjects to the forfeiture of 20*l.* and the concealed hops; and any perſon who ſhall privately convey away any hops, with intent to defraud the king and owner, ſhall forfeit 5*s.* a pound. And the duties are required to be paid within ſix months after curing, bagging, and weighing, on pain of double duty, two-thirds to the king, and one-third to the informer. No common brewer, &c., ſhall uſe any bitter ingredient inſtead of hops, on pain of 20*l.* Notice of bagging and weighing ſhall be ſent in writing to the officer, on pain of 50*l.* (6 Geo. cap. 21.) And tweny-four hours' notice ſhall be ſufficient, by 39 & 40 Geo. III. cap. 81. Officers ſhall make due returns to the commiſſioners, and leave a true copy with the planter, or owner, or forfeit 5*l.* 9 Anne, c. 12.

The owners of hops ſhall keep at their oaſts, &c., juſt weights and ſcales, permit the officer to uſe them, and aſſiſt in weighing, if required, on pain of 50*l.* A penalty of 100*l.* is inflicted for falſe ſcales and weights. No officer inferior to a ſuperviſor ſhall weigh hops between five in the evening and four in the morning, on forfeiture of 20*l.* (39 & 40 Geo. III. c. 81.) By the ſame, repealing the 14 Geo. III. c. 68. the owner or grower, before he begins to put any hops into a bag or pocket, ſhall mark on the outſide, in large legible characters, with durable ink or paint, his name and place of abode, on pain of forfeiting 50*l.* nor ſhall hops be bagged into any bag of greater weight than in the proportion of 10*lb.* for every 112*lb.* of the groſs weight of bag and hops, on pain of forfeiting 20*l.* The officer, after weighing, &c., hops for the purpoſe of charging the duty, ſhall mark in like manner on every bag or pocket the groſs weight, together with the year of growth, and the progreſſive number according to the number of bags charged to each owner or grower in each ſuch current year; counterfeiting ſuch marks incurs a penalty of 100*l.*; and wilfully defacing or obliterating them, or cauſing the ſame to be done, ſubjects to a forfeiture of 20*l.* The owners are allowed to uſe caſks inſtead of bags, under the ſame regulations. (6 Geo. cap. 21.) No hops ſhall be removed from the place of weighing, until twelve hours next after bagging, weighing, &c., unleſs the ſame ſhall have been reweighed by the ſuperviſor; and if any additional weight ſhall be found, the ſame ſhall be charged with the duty; and if any owner or grower ſhall convey away any ſuch hops, contrary to the meaning thereof, he ſhall forfeit 50*l.* for every ſuch offence. (39 & 40 Geo. III. c. 81.) If any perſon ſhall mix with hops any drug to alter the colour or ſcent, he ſhall forfeit 5*l.* a hundred weight. If any perſon ſhall unlawfully and maliciouſly cut hop-binds growing on poles, in any plantation, he ſhall be guilty of felony, without benefit of clergy. 6 Geo. II. cap. 37.

Hop-*bag*, in *Agriculture*, the name of the ſack-cloth bag in which the ſtoved and dried hops are ſtuffed in order to their being ſold. There are two ſorts of cloth employed in this intention, according to the nature and quality of the hops; ſuch as are of a bright fine colour and a good ſample, being put into ſuch bagging as is of a fine kind, under the denomination of *pockets*; but thoſe which have a dark colour into a coarſe heavy kind, termed *bags*: the former of theſe ſorts of hops is employed for ales, and all the finer kinds of malt-liquors, but the latter chiefly for the brewing of porter. It is ſuggeſted that the coarſe ſort of bagging-ſtuff is the beſt, where the hops are to be kept for ſome length of time.

The neceſſary lengths of theſe ſorts of bagging are about two ells and a quarter for the *bag*, and nearly the ſame for the *pocket*, each of them having an ell in width. The firſt, or bags, when the hops are of a prime quality, well cured, and trodden into them with tightneſs, will weigh about two and a half hundred weight; but the latter, or pockets, when of Canterbury pocketing, only about one and a half hundred weight.

In caſes where the variations from theſe ſtandards are in any degree conſiderable, the preparation or ſample may be ſuſpected with propriety.

Hop-*baſket*, the name of a kind of large flat baſket employed for carrying the hops in, during the period in which they are picked.

Hop-*bin*, the name of the crib or bin, into which the hops, after being picked from the bind, are thrown. It is moſtly conſtructed merely in a temporary way, by fixing four or more pieces of boards upon as many upright poſts ſet firmly into the ground as a frame, by means of nails. When finiſhed, they ſhould be full ſeven or eight feet in length, three feet in breadth, and the ſame in height, the ſide pieces at the ends projecting as a ſort of handles. Each end has a ſupport, which riſes two feet above the top of the frame; on the tops of which reſts a ſtraight pole, the whole length of the frame, or rather more; the whole ſtructure having ſomewhat the reſemblance of a ſmall market-booth, without a covering; only that, in the place of the flat ſurface for the reception of the wares, there is a canvas bag adapted to the ſize of the frame, hung within, ſo as nearly to reach the ground, in order to receive the hops as they are picked from the ſtems. Such as are formed eight feet in length are uſually termed *bins*, and thoſe of four feet in length *half-bins*. The contrivances of this nature ſhould conſtantly be well proportioned to the number of pickers that are employed, in order to prevent the loſs of labour, which would otherwiſe take place.

Hop-*clover*, the common name of a plant of the clover kind, which grows naturally in moſt meadows and paſture lands of the more dry deſcriptions, commonly flowering towards June, or the following month. It has been adviſed of late as beneficial in laying lands down to ſward, when combined with other ſeeds of the graſs kind; and is aſſerted to afford an excellent fodder, when ſown on the lighter ſorts of ſoils. See Clover.

Hop-*dag*, a name given to a ſort of lever formed from a long piece of ſtrong round timber, having a kind of fixed fulcrum or reſt at the lower part, the end of which is ſet or ſhod with a ſtrong piece of toothed iron, which firmly graſps and holds the bottom end of the hop-pole, when, by the action of the lever, the hop-pole is wrenched up from the ground, and much labour ſaved.

Hop-*harrow*, a name given to a ſort of harrow that is employed after the nidget by different hop cultivators, in order to bring the ſoil into a very fine ſtate of mould. It is conſtructed pretty much in the form and on the principle of the nidget, having only a ſmall wheel fixed in the front of it, in order to turn round at the ends of the rows, with more facility than would otherwiſe be the caſe. It is guided in the intervals or alleys, and the bruiſing of the binds prevented, by having a pair of handles faſtened on behind, and held by a man. The tool complete coſts about two guineas. An implement of this ſort is ſtated in the Middleſex Report to have there been found highly beneficial in the practice of Mr. Maynard; it is ſo conſtructed as to have ſomewhat the form of the ſnow-plough, being an equilatural triangle, the ſides of which are four feet in length, and the front-ones ſhod with old ſcythes; the whole being ſtrongly framed and put together, that it may bear to be loaded when it is made uſe of in the work.

It is ſuggeſted that, by drawing this tool once in a place in the intervals between the rows of plants, it is capable of rendering them "perfectly clean, and as ſmooth as the well rolled walk of a pleaſure ground," beſides, earthing up the rows in the ſame operation, which, in about ten days or a fortnight afterwards, may be readily formed by means of ſpades, into hills for the reception of the plants.

Hop-*hovel*, a term applied to a ſmall building or place of ſhelter, in which the buſineſs of picking the hops from the binds may be executed with convenience, in caſes in which the plantations are at ſome conſiderable diſtances from the houſes of the proprietors. In this way labour and expence may often be ſaved to the hop farmer.

Hop-*horn-beam*, in *Gardening*. See Carpinus.

Hop-*nidget*, a name given to a tool formed in a ſomewhat triangular manner, but of different dimenſions according to the diſtances of the alleys or intervals in which it is to be employed, having croſs bars or beams into which are fixed a number of hoes, proportioned to the breadths of the intervals in which they are to work, in ſuch a manner that the hinder part, which is the wideſt, may paſs along without doing any ſort of miſchief to the binds on the different ſides of it. A pair of handles is fixed to it behind by means of which it is directed in the execution of its work. It is uſually drawn by a ſingle horſe and managed by a boy; and in this ſtate is capable of cleaning two acres in the courſe of the day. In making uſe of it, care ſhould be taken that in completing the labour, the intervals or alleys be all gone over or croſſed in the ſame line of direction; as by this means every part of the ſurface, except the portions occupied by the hills, may be effectually cut over. The ſpaces forming the hills muſt afterwards be cleaned and rendered free from weeds by hand-hoeing. This tool ſhould continue to be made uſe of occaſionally as there may be neceſſity, until the hop plants begin to branch out in ſuch a way as to impede the paſſage of the horſe in the alleys or intervals of the rows. In this mode hop-plantations are capable of being kept in a clean condition and perfect order, at much leſs expence than by means of hand labour, either by the hoe, or digging over in the ſummer ſeaſon. The principal circumſtance that requires to be attended to in the nidget management of hop-grounds is that of preventing the binds from being injured, by the tool coming too much in contact with the poles during the performance of the work.

Hop-*oaſt*, the name of a ſort of oven or kiln in which the hops, after being ſeparated from the binds, are ſtoved or dried by being expoſed to proper degrees of heat under the direction of a perſon who has the excluſive management of the buſineſs. See Oast.

Hop-*peeler*, a term applied to a tool contrived for the purpoſe of forming the holes for ſetting the hop-poles in, in grounds of this kind; and which is a ſort of ſtrong iron crow, with a firm wooden handle placed croſſways at the top, and made thick and tapering to a point at the bottom part, ſo as to readily remove the earth and make way for the inſertion of the lower ends of the hop-poles, into the ſolid ground, in order to their ſtanding firmly for the ſupport of the binds.

Hop-*picker*, a term applied to the perſon who is employed in picking the hops from the binds, as ſoon as they are in a ſtate of maturity for the purpoſe. Numbers of people are engaged in this ſort of work in large hop-grounds.

Hop-*poles*, the name of the poles or ſtrong ſtakes which are forced into the firm ground for the purpoſe of the hop binds climbing up and twiſting round them, in order to their being ſupported and kept from trailing upon the ground. Poles of this kind are daily becoming more ſcarce and expenſive. In the account of the rural economy of the ſouthern counties of the kingdom, it is ſtated, that "the ſpecies of woods in uſe for hop poles are various. Formerly they depended much on the natural growth of the coppice woods of the country. But of late years, it has been the practice to make plantations for the eſpecial purpoſe of hop poles."

They are aſſerted to be held in eſteem by the planters of theſe diſtricts, ſomewhat in this order:

1ſt Cheſnut,
2d Aſh,
3d Sallow,
4th Red-willow,
5th Birch,
6th Maple,
7th Oak,
8th Hornbeam,
9th Beech.

Beſides theſe the alder, or œwler, the brown willow, and ſome other ſimilar ſorts of light woods, make excellent hop poles.

It has been hinted, by an intelligent hop cultivator, that the hop, as well as other climbing plants, may have a predilection or choice of particular woods as ſupporters; and that a rough ſoft bark may be preferred by them, to one which is more ſmooth and poliſhed. That of the maple is particularized, as its bark is peculiarly "ſoft and warm;" it being noticed that when the morning has been cold, the ſenſitive leader of a tender or freſh-poled vine has reclined its head againſt the velvet bark of the maple, while others held their's aloof, from chilly ſmooth barked poles. It is probable, that this may be a general law or ordinance of nature, among climbing plants, and may be eſſential to their preſervation, exhibiting, in a moſt palpable way, "the perception and ſtrength of vegetable inſtinct." Theſe plants, it is likewiſe well known, have their inſtinctive choice or predilection with regard to the thickneſs of the articles of their ſupport; being found to embrace with greater readineſs a pole that is not of too great thickneſs, than one which is of much thickneſs towards the bottom part. The uſual circumference of poles, at the butt-ends, may be rated at from about ſix to nine inches, tapering up to the top, where they are moſtly about the ſize of a ſtrong walking ſtick. The length is commonly about fifteen or twenty feet, but ſometimes more different ſorts of ground require poles of very different lengths. In the rich fertile hop grounds in the vicinity of Maidſtone, in Kent, the poles of grown hops uſually ſtand from about fourteen to ſixteen feet above the ſurface of the hills, and have from eighteen inches to two feet below the ſurface of the ground. But on grounds of leſs ſtrength, the poles are not found to riſe more than ten or twelve feet in height. For this reaſon, a variation of the quality of the ground is beneficial, as the poles, by rotting and decaying at the bottom parts, become ſhorter, and, after a few years, get too ſhort for ſtrong vines in rich ſtrong land. Yet it is not the cuſtom for them to be ſold or removed to leſs productive hop grounds for the ſupport of vines which have an inferior growth and luxuriance.

In theſe diſtricts it was found that the prices of hop poles varied, in 1790, from fourteen to forty ſhillings the hundred, in proportion to the ſize and quality of them; being commonly ſorted under three diviſions; *firſts*, *ſeconds* and *thirds:* but in 1797 they became conſiderably lower, "prime poles being then thirty ſhillings." They have, however, been conſtantly upon the advance ſince that period, and are at preſent become both extremely ſcarce and dear. The cuſtom with the new poles is occaſionally to have the bark ſhaved off, under the notion that it ſaves them from the worm; but ſome hop planters ſuppoſe that there is a warmth in the bark which is agreeable to the young vines; and though in two or three years the bark may drop off naturally, the ſurface of the wood, in the courſe of that time, has acquired a degree of ſoftneſs. Allowing a hard, ſmooth poliſhed pole to be unfriendly to the hop, it would obviouſly be improper to peel the poles.

In ſharpening or pointing the bottom ends of hop poles, it is uſual for the light ſhort ones to be done in the hand without any ſupport being required; but ſuch as are tall and heavy ſtand in need of ſome ſort of contrivance to keep them ſteady and upright. This is generally afforded by the ſimple contrivance of tying three poles of equal lengths together, at two or three feet diſtance from their tops, and then ſetting them up in the form of a ſort of triangle. This receives the top of the pole which is to be ſharpened between the points or horns of the triangle, and affords the neceſſary ſtay to it; there being a block of wood placed ſuitable below to work upon. It is common for this ſort of labour to be performed on new as well as old poles, before they are *ſtacked* up or ſet in piles; though occaſionally only juſt before the time of uſing them. It is uſual, in pointing ſuch poles as have been already in uſe, to ſtrike off the portions which have ſtood in the ground where they appear much decayed, and point the ſound parts above. But where ſuch bottom parts continue firm and ſound, they are re-ſharpened for another crop.

The ſtacking up of the poles is a buſineſs that is beſt performed immediately after the picking of the hops has been finiſhed. It is univerſally the practice, in the diſtrict of Weſt Kent, to ſet up the poles in a kind of conical piles containing from two to five hundred each. This is effected by three ſtout poles of equal lengths, being bound together a few feet from their tops, and their legs ſpread out ſo as to ſtand firmly. This forms the ſupport and ſtay of the pile while it is building, and afterwards; the poles being regularly dropped in on each ſide between the points of the three poles firſt ſet up, ſo as to be equal on every ſide, as on this the ſtability of the ſtack depends. The ſlope and diameter of the baſe of a pile is variable according to the length and number of poles which are ſet up together. A ſtack of three or four hundred of the long poles, met with about Maidſtone, will take up a circle of near twenty feet in diameter. It ſhould, however, be noticed, that the bottoms of the poles do not form one entire ring; but are collected into a ſort of bundles or diſtinct parcels, moſtly from three to ſix or eight in number; each portion being bound tightly together a few feet diſtant from the ground, by means of a ſtrong band formed from the twiſted vines, by which the wind is prevented from ſeparating the poles; and at the ſame time the openings between the ſeveral parcels give paſſage to violent blaſts, and prevent in ſome meaſure the piles from being wholly thrown down; an accident, however, which rarely occurs in ſuch grounds as are tolerably ſcreened. But, in high expoſed ſituations, where quantities of theſe poles are often piled up for ſale amongſt the planters, it is no unuſual thing for the piles to be blown down, to the utter deſtruction of ſheep and other animals ſheltering underneath them.

The continuance or laſting of hop poles depends greatly on the ſort of wood which is in uſe and the time of its growth, as well as in ſome meaſure the quality of the ſoil, and the expoſure in which it has grown. Cheſnut poles of eighteen or twenty years growth, are in general eſteemed the moſt durable of any. It has been confidently aſſerted, that a hop pole of this ſort has been employed in a hop ground for upwards of thirty years; but the uſual duration of poles is from about five to twelve years; or thereabouts. When the poles become no longer uſeful for the ſtrong growing plants, they are moſtly either transferred to thoſe of leſs growths, or laid by for uſe in young plantations, being ultimately converted to the purpoſes of fire wood, or the making of charcoal for being mixed with the coke of coal in drying the produce. They are worth about five or ſix ſhillings the hundred in each of theſe views.

The annual expence of poles, taking the new ones at thirty ſhillings, the number made uſe of at three thouſand per acre, their duration eight years, and the value of the old refuſe ones at five ſhillings the hundred, was formerly about five pounds the acre; but at preſent it is in all probability nearly, if not quite, double that ſum. On account of this great expence of poles, and its chiefly ariſing from the decay of the parts inſerted into the ground, and the miſchief that frequently happens on their being broken off at the ſurface of the ground, in the time the crop is ripening, it would ſeem to be a deſirable object to prevent the deſtruction of that part as much as poſſible. In order to effect this, *charring* the parts has been recommended as a deſirable plan, eſpecially thoſe parts which are expoſed between the air and moiſture cloſe to the ſurface of the ground, as the decay generally commences in theſe places the firſt. See Charring *Poſts*.

Hop-*ſhim*, the name of an implement of the ſhim kind uſed in hop-grounds, and conſtructed with a ſtrong frame, ſomewhat in the way of the common wheel-barrow, having feet or teeth which cut up or drag out all ſuch weeds as may infeſt the land, while they break it down and render it fine at the ſame time. According to the Report of Kent, this is a ſort of tool that may be alſo beneficially employed in clearing ſummer fallows from weeds. When properly conſtructed it coſts about a couple of guineas. It has great power in working-over land when well managed. See Shim.

Hop-*tree*. See Holly.

Hop-*trefoil*, a common name often applied to a plant of the trefoil kind, and ſometimes to that of hop-clover. See Trefoil.

Hop, *Wild*. See *Shrub* Trefoil.

HOPE, in *Ethics*, is the deſire of ſome good, attended with a belief of the poſſibility, at leaſt, of obtaining it, and enlivened with joy, greater or leſs, according to the greater or leſs probability of our poſſeſſing the object of our hope. Alexander, preparing for his Aſian expedition, diſtributed his hereditary dominions among his friends; allotting to ſome villages, to others boroughs, to others cities; and being aſked what he had reſerved for himſelf, replied, *Hope*.

Pindar, as cited by Plato (De Repub. l. 5.) calls hope the nurſe of old age. It was virtue, according to Cicero, that inſpired the hope of immortality, and that ſame immortality animated hope. There is nothing melancholy, ſays he, (De Senect. c. 1.) in death, which leads to immortality. The heathens deified hope. Cicero (De Leg.) ſpeaks of one of the temples of this goddeſs. Livy mentions that which ſtood in the market for herbs, and of another which Publius Victor erected to her in the ſeventh region. M. Fullius, the cenſor, erected another to her near the Tiber. The Greeks alſo worſhipped this divinity under the appellation Ελπις, *Elpis*. Hope is repreſented upon ſome ancient monuments, but oftener upon the medals of the emperors, ſometimes with theſe words, "Spes publica," "Spes populi Romani;" ſometimes with a cornucopia, or with flowers and fruits, or a bee-hive. We find her often with one hand reſting upon the altar, which M. Aurelius Pacorus dedicated to her. As ſhe had her temples and altars, ſhe had alſo, without doubt, her ſacrifices; but antiquity gives us no account of the victims that were offered to her.

HOPE, in *Geography*, a river of Jamaica, which runs into the ſea; five miles S. of Kingſton.—Alſo, a large bay at the N.E. corner of Nootka ſound, between "Point Breakers," N. lat. 49° 15'. E. long. 233° 20', and "Woody Point," N. lat. 50°. E. long. 232°.—Alſo, a bay in the Engliſh channel, on the coaſt of Kent, between Sandwich and Ramſgate.—Alſo, a harbour on the W. coaſt of Quadra and Vancouver's iſland, in the N. Pacific ocean.—Alſo, a ſmall iſland near the coaſt of Rhode iſland, in America.—Alſo, two ſmall iſlands, near the N.E. coaſt of New Holland, ſo called by captain Cook, when his ſhip was reſcued from its imminently perilous ſituation off cape Tribulation. S. lat. 15° 41'. W. long. 214° 36'.—Alſo, a Moravian ſettlement in Wachovia, North Carolina, in Surry county, where the united brethren have a meeting.—Alſo, a townſhip in the county of Durham, Upper Canada, W. of Hamilton, and fronting lake Ontario.

Hope's *Advance Bay*, a bay in Hudſon's ſtrait; 100 miles W. of Chidley.

Hope's *Noſe*, a cape in the Engliſh channel, on the coaſt of Devonſhire. N. lat. 50° 28'. W. long. 3° 27'.

HOPEA, in *Botany*, ſo named by Dr. Garden, and adopted by Linnæus, in honour of their mutual friend the late Dr. John Hope, profeſſor of botany at Edinburgh, who died in 1786. This gentleman richly deſerves commemoration, as being one of the earlieſt lecturers on the vegetable phyſiology, as well as an experienced practical botaniſt. Thoſe who knew his perſonal merits, will readily accede to any thing that may ſerve to embalm ſo worthy a name. The genus originally choſen for this purpoſe has proved unfortunate, being now, juſtly we believe, referred by l'Heritier to *Symplocos*. See Tr. of Linn. Soc. v. 1. 176, and Willd. Sp. Pl. v. 3. 1436. It is ſingular that the Linnæan *Alſtonia*, named by Mutis after Dr. Hope's predeceſſor, ſhould have preciſely the ſame fate, being alſo a *Symplocos*. We are therefore obliged to admit as *Hopea* a little inconſiderable Eaſt Indian plant, which Willdenow and Vahl have ſo denominated, though we are by no means ſatisfied of its being diſtinct from *Exacum*. Dr. Buchanan had deſtined the *Dipteroſpermum* of the younger Gærtner to commemorate his friend and preceptor, and it is much to be wiſhed that ſo fine a genus had been adopted as *Hopea*.—Vahl. Enum. v. 1. 3. Willd. in Nov. Act. Soc. Amic. Hiſt. Nat. Berol. v. 3. 435. *Vahl*.—Claſs and order, *Monandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Gentianæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in four deep, lanceolate, ſpreading, equal ſegments. *Cor.* of one petal, funnel-ſhaped; tube ſhort inflated; limb in four equal, ſpreading, or reflexed ovate ſegments. *Stam.* Filaments two, inſerted into the tube, very ſhort, linear, oppoſite, one of them ſhorteſt and barren; anther ſolitary, globoſe, two-lobed. *Piſt.* Germen ſuperior, roundiſh; ſtyle cylindrical, very ſhort; ſtigma capitate, globoſe. *Peric.* Capſule roundiſh, of two valves and one cell. *Seeds* numerous, minute.

Eſſ. Ch. Calyx in four deep equal ſegments. Corolla of one petal, funnel-ſhaped, four-cleft, equal. One barren ſtamen. Capſule with two valves, one cell, and many ſeeds.

1. H. *dichotoma*. The only ſpecies gathered by the Rev. Dr. Rottler at Tranquebar. We have never ſeen a ſpecimen, but a drawing communicated by Lieut. Col. Hardwicke, as the *Exacum puſillum* of Roxburgh, anſwers ſo well to the deſcription in Vahl, that we have no doubt concerning it. This is a ſmall, ſmooth, pale, annual, fibrous-rooted plant, flowering in December. The *ſtem* is from one to three inches high, branched, forked, leafy, ſlender, ſquare, with membranous angles. *Branches* alternate or oppoſite, ſpreading. *Leaves* oppoſite, ſeſſile, ſmall, acute, entire, three-ribbed; the lower ones ovate, upper ones gradually narrower, and uppermoſt awl-ſhaped. *Flower-ſtalks* very ſhort, ſolitary in the forks of the branches, three together at the extremities. *Flowers* ſmall, yellow, with a pale tube. *Seeds* red.

If the capſule be really of one cell, and the ſtamens conſtantly two, one of them barren, this plant may poſſibly conſtitute a good genus; but in our drawing the capſule appears of two cells, and on the whole we are more diſpoſed to think it an *Exacum*, notwithſtanding the peculiarity of the ſtamens.

HOPEWELL, in *Geography*, a townſhip of America, in Cumberland county, New Brunſwick, on Chepodil river, which runs into a northern arm of the bay of Fundy, and is navigable for four or five miles.—Alſo, the name of three townſhips in Pennſylvania; *viz.* in York, Huntingdon, and Waſhington counties.—Alſo, a townſhip in Hunterdon county, New Jerſey, on Delaware river, 14 miles W. of Princeton, and 11 above Trenton. In 1790 it contained 2320 inhabitants.—Alſo, a townſhip in Cumberland county, New Jerſey.

Hopewell *Head*, a cape in Hudſon's bay. N. lat. 58° 10'. W. long. 78°.

HOPFGARTEN, a town of Germany, in the archbiſhopric of Salzburg; 38 miles S.W of Salzburg.

HOPITAL, L', a town of France, in the department of Mont Blanc, and chief place of a canton, in the diſtrict of Chambéry. The place contains 662, and the canton 8346 inhabitants, on a territory of 157½ kiliometres, in 15 communes.—Alſo, a town of France, in the department of the Rhône and Loire; 17 miles S. of Roanne.—Alſo, a town of France, in the department of the Lot; 24 miles N.E. of Cahors.

HOPKINS, John, in *Biography*, one of the principal verſifiers of the pſalms at the time of the Reformation, with Sternhold. Theſe were the fathers of metrical pſalmody in our country, equally injurious to the divine poetry of the pſalmiſt, and to the compoſition of ſacred muſic. The melodies to which theſe verſions are ſung, were chiefly German. See Psalmody.

Hopkins, Ezekiel, was born at Sandford, in Devonſhire, about the year 1633. In 1649, he became a choriſter of Magdalen college, Oxford, and after he had taken his degree of B.A. in 1653, he was appointed uſher of the adjoining ſchool. In 1669, he went to Ireland as chaplain to lord Roberts, afterwards earl of Truro, who was appointed lord lieutenant. He married his lordſhip's daughter, and was made dean of Raphoe. Upon his return to England, lord Roberts recommended him ſo ſtrongly to his ſucceſſor lord Berkley, that, in 1671, he was conſecrated biſhop of Raphoe, from which ſee he was tranſlated, in 1681, to that of Londonderry, where he continued till the war which broke out between the ſupporters of the revolution, under king William, and the partiſans of king James, headed by the earl of Tyrconnel, when he retired to England. He was now choſen miniſter of Aldermanbury, where he ſhortly after died, at the age of fifty-ſeven. After his death, his poſthumous works were publiſhed in one volume folio. His moſt valuable piece is "An Expoſition of the Lord's Prayer," firſt printed in 4to. in 1692, to which were afterwards added ſermons on Providence, and the advantage of reading and ſtudying the holy ſcriptures. Gen. Biog.

Hopkins, William, a learned divine of the church of England, was born at Monmouth in the year 1706. He received the elements of a learned education at his native town, whence he was ſent to All-Souls, Oxford, in the year 1724. He was admitted to deacon's orders in 1728, and in the following year undertook the curacy of Waldron, in Suſſex. In 1731, he was preſented to the vicarage of Bolney, in the ſame county. In 1753, he publiſhed anonymouſly, "An Appeal to the Common Senſe of all Chriſtian People, more particularly the Members of the Church of England, with regard to an important Point of Faith and Practice, impoſed upon their Conſciences." This piece excited much attention, and created no little alarm among the believers in the doctrine of the Trinity. Many anſwers were written, but at length Dr. Thomas M'Donnell wrote an octavo volume againſt the principles contained in the "Appeal," to which Mr. Hopkins replied. The controverſy was carried on many years, and our author publiſhed other tracts on the ſame ſubject. In 1756, he was elected maſter of the grammar ſchool of Cuckfield, without any other conditions than that of taking the oaths to government. In the year 1766, Mr. Hopkins undertook the curacy of Slaugham, and continued to officiate there many years, and in his own pariſh of Bolney, upon what he judged to be the goſpel plan. He was an active and zealous promoter of a petition to parliament for relief, in the matter of ſubſcription to the liturgy and thirty-nine articles of the church, and put forth ſome able works in defence of the cauſe. The laſt piece which he ſent to the preſs was "Exodus, a corrected Tranſlation, with Notes critical and explanatory." This was in the year 1784; almoſt immediately after this, Mr. Hopkins's health began to decline, and his mental faculties were greatly impaired before his deceaſe, which happened in 1786, when he had attained to his eightieth year. Mr. Hopkins was an Arian in his religious faith, and admitted the lawfulneſs of praying to Jeſus Chriſt, but he could not join in the invocations to him as being himſelf God. Mr. Hopkins was poſſeſſed of great knowledge in the original languages of the ſcriptures, and was a moſt diligent ſtudent in theology.

Hopkins, or *Hopkinſville*, in *Geography*, a townſhip of Caledonia county, in Vermont.

HOPKINTON, a townſhip of Middleſex county, Maſſachuſetts, incorporated in 1715, and containing 1372 inhabitants. The rivers Concord and Providence receive each a branch from this townſhip; and theſe ſtreams furniſh ſeats for ſeven or eight griſt-mills, a number of ſaw-mills, iron-works, &c.—Alſo, a townſhip in Waſhington county, Rhode iſland, on the W. line of the ſtate, on ſeveral branches of Pawcatuck river; containing 227 inhabitants.

HOPLITES, Hoplitæ, formed of ὅπλον, *armour*, in *Antiquity*, were ſuch of the candidates at the Olympic and other ſacred games as ran races in armour.

One of the fineſt pieces of the famous Parrhaſius, was a painting which repreſented two hoplites; the one running, and ſeeming to ſweat large drops; the other laying his arms down, as quite ſpent, and out of breath. Pliny, lib. xxxv. cap. 10. and Paſchal De Coronis, lib. vi. cap. 14.

HOPLITIS Lapis, in *Natural Hiſtory*, a name given by ſome of the writers among the ancients to a ſtone of a ſhining braſs-like appearance, looking like the ſurface of a poliſhed braſs armour worn in thoſe times. It is eaſy to conclude, from this account, that the hoplites was one of our mundics.

HOPLITODROMOS, formed of ὅπλον, *armour*, and δρέμω, *I run*, in the ancient gymnaſtic ſports, a term applied to ſuch perſons as went through thoſe toilſome and robuſt exerciſes, in complete armour; by which the exerciſe became much more violent, and the wearing of armour, in the time of battle, much more eaſy.

HOPLOCHRISMA, a term uſed, by the ancient writers in *Medicine*, for the anointing a ſword, or other weapon, with which a perſon had been wounded, in order to the curing of the wound; ſo early was the idle notion of curing by ſympathetic remedies received into the world. Some late authors have alſo uſed the word in a very different ſenſe, namely, for the anointing the points of darts or ſwords with poiſonous ingredients in order to render the leaſt wound given with them fatal; a practice moſt known, as it is ſaid, among the ſavage inhabitants of America.

HOPLOMACHI, Ὁπλομαχοι, compoſed of ὅπλον, *armour*, and μαχομαι, *I fight*, in *Antiquity*, were a ſpecies of gladiators, who fought in armour; either completely armed from head to foot, or only with a caſque and cuiraſs.

HOPPER, a veſſel wherein ſeed-corn is carried at the time of ſowing.

The word is alſo uſed for that wooden trough in a mill, into which the corn is put to be ground.

HOPPET, in *Mining*, is a ſmall hand-baſket or whiſket uſed for holding and carrying ore, &c. It alſo means a ſquare or oblong diſh or box of wood, narroweſt at the bottom, holding 14 or 16 pints, which is uſed, level full, in the meaſuring of lead ore by the bar-maſters, in the low and high peaks or hundreds of Derbyſhire.

HOPPLE, a term applied to different animals, as the horſe, ſheep, &c. which ſignifies the fettering or reſtraining of them, by tying their two fore legs together with a ſhort ſtrong ligature or band of ſome ſort or other.

HOPTON, Arthur, in *Biography*, an Engliſh mathematician, was ſon of ſir Arthur Hopton, and born in Somerſetſhire. He was educated at Lincoln college, Oxford, and after taking his degree of B.A., removed to the Temple, where he lived in habits of friendſhip with the learned Selden. He died in 1614, a very young man, not having attained to more than his twenty-ſixth year. He wrote a treatiſe on the "Geodetical Staff"; "The Topographical Glaſs, containing the Uſes of that Inſtrument, the Theodolite, Plane Table, and Circumferentor"; "A Concordance of Years, containing a new and a moſt exact Computation of Time, according to the Engliſh Accompt;" "Prognoſtications for the Year 1607 and and 1614."

Hopton, Susanna, an ingenious lady, was deſcended from an ancient family in Staffordſhire, and was born in 1627. In her youth ſhe was drawn over to the church of Rome, but ſubſequent enquiry reſtored her to the Proteſtant communion. She died at Hereford in 1709; as an author, ſhe is known by ſeveral books on practical piety, and by an hexameron or meditations on the ſix days of the Creation, &c.

HOQUETUS, Hochetus, or *Hocetus*, a term uſed in the old Latin tracts, and in the cenſures of muſic by the heads of the church and grave divines, ſeems to imply a fantaſtical diviſion, which by the ſudden leaps and breaks, or diſcontinuity of voice, reſembled a hiccup, in French *hoquet*. "They interſect the melodies with hoquets, ſlide about in diſcant, and ſometimes even crowd and load the chants with vile third and fourth parts, triplis et motetis vulgaribus."

HOR, in *Scripture Geography*, a mountain of Arabia Petræa, on the confines of Idumæa. Here Aaron died and was buried. See Aaron.

HORACE, Quintus Horatius Flaccus, in *Biography*, one of the moſt celebrated of the Roman poets, was born at Venuſium in the year 65, B.C. His father was the ſon of a freed-man, and followed the employment of a tax-gatherer; but notwithſtanding the meanneſs of his origin, he felt the importance of a good education, the advantages of which he reſolved his ſon ſhould enjoy. He accordingly took him to Rome, and cauſed him to be inſtructed in all the branches of knowledge which were taught to young people at that time. At the age of eighteen he was ſent to Athens for the purpoſe of purſuing philoſophy and Greek literature, which was become faſhionable among the Romans. While he was in that city he was noticed by Brutus, who took him into his army and made him tribune: but Horace was more diſtinguiſhed by his wit than illuſtrious for his valour, and at the battle of Philippi he is ſaid to have thrown away his ſhield and fled. He was now reduced to great difficulties, even to a ſtate of indigence, having nothing to depend on but his literary talents. He recommended himſelf to Virgil, who obtained for him the patronage of Mecænas. To this patron of letters he rendered himſelf ſo agreeable that he made him his familiar companion, and took him to Brunduſium, in that journey which he has ſo well deſcribed in verſe. Mecænas procured from Auguſtus the reſtitution of Horace's eſtate, which he had forfeited by the part that he took in the war under Brutus, and introduced him to the emperor, who became greatly attached to him, and would have made him his private ſecretary, but the poet declined this high honour, preferring the independence of a private life to the buſineſs of a court. Having no ambitious views, and deteſting parade and ſplendour, he determined to remain his own maſter. In the latter part of his life he retired to the country, where he indulged himſelf in philoſophical eaſe, which he has admirably deſcribed in his odes. He died eight years before the Chriſtian era, and was buried near his friend and patron Mecænas, whoſe death is ſaid to have haſtened his own. He appears to have had many friends among perſons of rank, whom he addreſſed with eaſy familiarity, and he was ready to do friendly offices in the way of advice and recommendation. No ancient writer has been ſo popular as Horace: the variety of his manner, and of the ſubjects treated of, has rendered him the favourite of the moſt different taſtes. His odes are models of that kind of compoſition in the Latin language. His *Epiſtles* and *Satires* abound in moral maxims expreſſed with vigour; in acute obſervations on human life, and in pleaſant ſtories related with eaſe and vivacity. The *Art of Poetry* diſplays much ſound ſenſe and good taſte, but the precepts contained in it are deſultory and without method. The beſt editions of this author are thoſe of Lipſ. 1752; and of Glaſgow in 1744: but the impreſſions of Horace are ſo numerous as to defy enumeration. The tranſlation by Francis is highly eſteemed.

HORADADA, in *Geography*, a river of South America, which runs into the Caribbæan ſea; 50 miles E. of Cape Aguja.

HORADNIC, a town of Auſtrian Poland, in Galicia; 60 miles N.W. of Zytomiers.

HORÆA, Ὡραια, in *Antiquity*, ſolemn ſacrifices, conſiſting of fruits, &c. offered in ſpring, ſummer, autumn, and winter, that heaven might grant mild and temperate weather. Theſe, according to Meurſius, were offered to the goddeſſes, called Ὡραι, *i.e. Hours*, who were three in number, attended upon the ſun, preſided over the four ſeaſons of the year, and had divine worſhip paid them at Athens. Potter, Archæol. Græc. lib. ii. cap. 20, tom. i. p. 430.

HORAIDAN, in *Geography*, a town of Perſia, in Farſiſtan; 84 miles N.W. of Schiras.

HORAPOLLO, or Horus Apollo, in *Biography*, an Egyptian grammarian, who taught firſt at Alexandria, and afterwards at Conſtantinople in the time of Theodoſius. There remain of his, two books on the Egyptian Hieroglyphics, printed by Aldus in Greek, in 1505. They were afterwards tranſlated into Latin, and ſeveral times reprinted. The beſt edition is that of de Pauw, Gr. and Lat. with notes, Utrecht, 1727, 4to.

HORARY, ſomething relating to *horæ*, *hours*. See Hour.

Horary *Circle of the globe*. See Circle.

Horary *Circles*. See Hour-*circles* and Circle.

Horary *Circles*, or *lines*, in *Dialling*, are the lines or circles which mark the hours on ſun-dials.

HORARY *Motion of the earth*, is the arc it deſcribes in the ſpace of an hour.

This is nearly fifteen degrees; for the earth completes its revolution through 360° in a day, or twenty-four hours, and the twenty-fourth part of 360 is 15; though this is not the exact meaſure of the horary arc, becauſe the earth moves with different velocity, according to its greater or leſſer diſtance from the ſun; but it is near enough for ordinary computations. See EQUATION *of time*.

HORATII, in *Biography*, the name of three brothers who diſtinguiſhed themſelves in the Roman hiſtory, and who fought againſt the three Curiatii of Alba in the year 667 B.C. Two of them were ſlain, but the third ſlew all his antagoniſts. On his return to Rome he met his ſiſter, who had been betrothed to one of the Curatii, and reproaching him for what he had done, he ſlew her alſo. His great ſervices to his country were conſidered as an extenuation of his crime. Univer. Hiſt. See CURIATII.

HORAWER, in *Geography*, a town of Hindooſtan, in Bahar; 42 miles S.W. of Arrah.

HORAZDIOWITZ, a town of Bohemia, in the circle of Prachatiz, ſituated on the river Ottawa; 22 miles N.W. of Prachatiz.

HORB, a town of Germany, in the county of Hohenberg, ſituated on the Neckar, having a conſiderable trade in woollen goods; 28 miles S.W. of Stuttgart.

HORBY, a town of Sweden, in the province of Skone; 24 miles S.W. of Chriſtianſtadt.

HORCA, a river of Sweden, riſing in the mountains bordering on Norway, and running into the Regunda at Lit, in Jamtland.

HORCAJADA, a town of Spain, in the province of Leon; 40 miles E. of Civdad Rodrigo.

HORCAJO, a town of Spain, in New Caſtile; 27 miles S.S.W. of Hueta.

HORCAN, a mountain of Grand Bukharia, S. of Balk.

HORCUS LAPIS, the name of a ſtone mentioned by the writers of the middle ages as uſeful in ſoldering ſilver and other metals. All the deſcription they give of it is, that it was black, and was eaſily reduced to powder. It was called alſo catemia.

HORD, HORDA, a Tartarian term, and literally denoting a *multitude*, in *Geography*, is uſed for a company or tribe of wandering people, which have no ſettled abode or habitation, but ſtroll about, dwelling in chariots, or under tents, to be ready to ſhift as ſoon as herbage, fruits, and the preſent province is eaten bare.

HORD is more properly the name which the Tartars, who inhabit beyond the Wolga, in the kingdoms of Aſtracan and Bulgaria, give to their villages.

A hord conſiſts of fifty or ſixty tents ranged in a circle, leaving an open place in the middle. The inhabitants of each hord uſually form a military company or troop; the eldeſt whereof is commonly the captain, and depends on the general or prince of the whole nation.

HORDEATEM, a liquid medicine, made of barley, boiled till it burſt.

Sometimes other ingredients are added, as the cold ſeeds, almonds, and the like.

HORDEOLUM, or STYE, ſignifies, in *Surgery*, a ſmall tumour ſituated upon the edge of the eye-lid, and ſeldom exceeding a barley corn in ſize, from which laſt circumſtance the former appellation has been derived. According to Scarpa, ſties originate particularly, often towards the inner canthus. A ſwelling of this ſort is very circumſcribed, and preſents itſelf either in an inflamed, or a ſuppurating ſtate, or elſe as a mere indurated tumour, unaccompanied by inflammation.

An inflamed ſtye is commonly very red and painful, and bears a cloſe reſemblance to a little boil, or an inflamed encyſted tumour. Richter ſuſpects, that a ſtye is ſometimes one of the glands of Meibomius in a ſtate of inflammation. The diſeaſe is in general quite of a local nature, although the circumſtance of ſome perſons being particularly often troubled with the complaint has given riſe to ſuſpicions of there being occaſionally a conſtitutional or internal cauſe. Both Richter and Scarpa concur in imputing the frequency of ſties in particular ſubjects to a foul diſordered ſtate of the alimentary canal, induced by improper food, the abuſe of ſpirits, &c. We will not pretend to decide concerning the truth of this ſtatement, nor about the connection, which the firſt of theſe writers deſcribes, as occaſionally exiſting between the menſes, the cure of the tinea capitis in children, &c. and the origin of ſties.

The cure of an inflamed ſtye requires the employment of external emollient applications, or ſuch as promote ſuppuration. The tumour always ſuppurates, and the ſooner it is made to do ſo, the more quickly is the patient freed from all inconvenience. Attempts to diſperſe the ſwelling are, for the moſt part, unavailing, or if the inflammation is reſolved, the ſtye is ſtill left in an indurated ſtate. When the tumour has already ſuppurated, it is alſo adviſable to perſiſt in the uſe of emollient remedies, and promote the diſcharge until all the hardneſs is removed. An exceedingly troubleſome induration is apt to remain when the ſuppuration has been checked too ſoon, eſpecially if the ſtye has been of large ſize. After the ſuppurative ſtage, a weak ſolution of acetite of lead will commonly ſerve for the diſperſion of the remaining redneſs and ſwelling.

The indurated ſtye is uſually nothing more than the remains of one, that has paſſed through the inflammatory ſtage, the ſuppuration having either been checked too ſoon, or prevented altogether by means put in practice for the reſolution of the inflammation. The tumour becomes a cauſe of ſerious annoyance, partly becauſe it often falls into a painful inflamed ſtate, and partly becauſe it obſtructs the motions of the eye and eye-lids. It is even alleged, that the indurated ſtye may aſſume a malignant character, whence the ſwelling has been ſometimes called ſcirrhous. Richter ſtates, that in this ſtage emollients and other applications do no good, and he adviſes the ſurgeon to wait till the tumour ſpontaneouſly inflames, when ſuppuration is to be excited by ſome ſtimulating dreſſing, and kept up until the hardneſs ſubſides. Perhaps it is preferable (and we prefer the plan) to dip the point of a camel hair pencil in ſulphuric acid, and touch the ſtye with it a few times, until the cure is effected.

Scarpa has made ſome excellent obſervations on this diſeaſe. Among other things, we learn from him, that the inflammation of the ſtye, like that of boils, has a tendency to deſtroy a part of the cellular membrane, which is the reaſon why the tumour can hardly ever be completely reſolved. He ſtates, that reſolution can only be accompliſhed, when the inflammation is confined to the ſkin, a caſe where cold applications, eſpecially ice, may prove ſucceſsful. But when any of the cellular membrane is deſtroyed, Scarpa recommends the bread and milk poultice, which is to be changed very often. When a white point makes its appearance on the apex of the tumour, this author diſapproves of being in a hurry to let out the ſmall quantity of ſerum which lies between the ſkin and ſloughy cellular membrane. He prefers waiting till the ſkin has become as thin as poſſible, and breaks of itſelf, ſo as to give vent not only to the ſerous fluid, but alſo to the dead cellular ſubſtance, which conſtitutes the chief part of the diſeaſe. When the contents are ſlow in making their eſcape, Scarpa adviſes preſſing them out.

Should a portion of ſloughy matter remain in the ſwelling a long while undetached, this eminent ſurgeon recommends touching the inſide of the ſtye with ſulphuric acid a few times, by means of a camel-hair pencil.

HORDEUM, in *Botany*, an ancient Latin name, of whoſe meaning or etymology we find no account or conjecture worth tranſcribing. Barley.—Linn. Gen. 39. Schreb. 54. Willd. Sp. Pl. v. 1. 472. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 155. Juſſ. 32. Tourn. t. 295. Lamarck. Illuſtr. t. 499. Gærtn. t. 81.—Claſs and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Common Receptacle* elongated into a ſpike, jointed, brittle, compreſſed. *Cal.* Glumes lateral, three together, each of two narrow, pointed valves, containing one ſeſſile flower. *Cor.* of two valves; the lower one ſwelling, angular, ovate, pointed, longer than the calyx, ending in a long ſtraight awn; the inner valve lanceolate, flat, ſmalleſt. *Stam.* Filaments three, capillary, ſhorter than the corolla; anthers oblong. *Piſt.* Germen turbinate, ſomewhat ovate; ſtyles two, villoſe, reflexed; ſtigmas feathery. *Peric.* none, except the permanent corolla, falling off with and containing the ſeed. *Seed* oblong, ſwelling, angular, pointed at each end, above marked with a longitudinal furrow.

Obſ. In ſome ſpecies all the three flowers are perfect in all their parts, and fertile; in others the lateral ones are male, the central one only being hermaphrodite and fertile.

Eſſ. Ch. Common receptacle toothed and excavated. Calyx lateral, ternate, two-valved, ſingle-flowered.

The ſpecies of *Hordeum*, ten in Willdenow, may be divided into ſuch as come under the popular denomination of corn, and ſuch as are generally reckoned graſſes. The former are four; the latter ſix, and theſe laſt are of little or no value, but rather detrimental to the farmer.

H. *vulgare.* Linn. Sp. Pl. 125. Ehrh. Pl. Off. 421. Lob. Ic. 28. (H. polyſtichum vernum; Ger. em. 70.)—Flowers all perfect, awned; two of the rows more erect than the reſt.—This is our common cultivated Barley, ſaid to have been found wild in Sicily and Ruſſia. It is annual. The *flowers* and *ſeeds* are diſpoſed indiſtinctly in ſeveral rows, with very long, compreſſed, rough awns. There is a ſuppoſed variety, termed *Hordeum cœleſte*, in which the huſk, or corolla, does not ſtick to the ſeed; and another with black ſeeds, ſaid by Willdenow to be biennial.

H. *hexaſtichum.* Linn. Sp. Pl. 125, has ſix rows of ſeeds; *H. diſtichum*, ibid. but two. The latter is figured in Ger. em. 70. f. 1. It is much to be doubted whether theſe are more than varieties.

H. *Zeocriton.* Linn. Sp. Pl. 125. Schreb. Gram. t. 17. Ehrh. Herb. Exſicc. 13; has two rows of more crowded, ſpreading, and longer ſeeds, which give it a peculiar aſpect.

Of the graſſy ſpecies are

H. *murinum*, ſo called from *mus*, *muris*, a mouſe, and not from *murus*, a wall, though it is uſually named Wall Barley in Engliſh, is very common by way-ſides. See its figure in Curt. Lond. faſc. 5. t. 9. Mart. Ruſt. t. 43. Engl. Bot. t. 1971.

H. *pratenſe.* Mart. Ruſt. t. 108. Sm. Rel. Rudb. 12. f. 1. Engl. Bot. t. 409, is known from the laſt by its perennial root, taller upright ſtem, and by having all the calyx-glumes narrow and briſtle-ſhaped.

H. *maritimum.* Mart. Ruſt. t. 44. Knapp. t. 106. Engl. Bot. t. 1205. (H. marinum; Hudſ. 57.)—A ſea-ſide graſs, very curiouſly diſtinguiſhed by Hudſon from *H. murinum* by the internal glumes of the lateral flowers being dilated and half ovate. It is alſo a more glaucous and ſmoother plant, with more compact ſpikes. Curtis confounded it with *murinum*, and yet mentions it as known by the name of Squirrel-tail graſs in the Iſle of Thanet, where it is found very pernicious, by ſticking into the gums of horſes, and rendering them ſo ſore as to prevent the animal's feeding.—Theſe three are the only Britiſh ſpecies of *Hordeum*; the ſecond of them, *pratenſe*, is the *nodoſum* of Linnæus, but he quotes for it a ſynonym of Dillenius in Ray's Synopſis, t. 20. f. 2, which belongs to *Alopecurus bulboſus*.

H. *bulboſum.* Linn. Sp. Pl. 125. Sm. Prodr. Fl. Græc. Sibth. v. 1. 73. Fl. Græc. t. 98, a native of the Levant, has been by ſome confounded with the Linnæan *nodoſum*, but is a larger and very diſtinct ſpecies. This is *H. ſtrictum*, Desfont. Atlant. v. 1. 113. t. 37; and is alſo well figured in Barrel. Ic. t. 112. f. 2.

For the culture and produce, &c. of barley, ſee Barley. For the regulation of the price, ſee Corn.

HORDICALIA, or Hordicidia, in *Antiquity*, a religious feaſt held among the Romans, wherein they ſacrificed cattle big with young.

The word hordicidia is formed of *horda*; which Feſtus explains by *prægnans*, *pregnant*; and *cædo*, *I ſacrifice.* Ovid, in his Faſti, lib. iv. ver. 631. deſcribes *horda* or *forda*, to be *bos prægnans*; of φορος, *gravida*.

This feaſt fell on the fifteenth of April; on which day they ſacrificed thirty cows, big with calf, to the goddeſs Tellus, or Terra, Earth: ſome of them were ſacrificed in the temple of Jupiter. The calves taken out of their bellies were burnt to aſhes firſt, by the pontifices; afterwards by the eldeſt of the veſtal virgins.

Alexander ab Alexandro, Genial. Dier. writes *hordalis dies*; and from him, ſome of the moderns call the feaſt *hordalia*; but Varro writes it *hordicalia*, and Feſtus, *hordicidia*.

HORDY, in *Geography*, a town of Hindooſtan, in Dowlatabad; 28 miles N. of Darore.

HOREB, in *Scripture Geography*, a mountain of Arabia Petræa, ſo near to mount Sinai that Horeb and Sinai ſeem to be two eminences of the ſame mountain. Sinai lies eaſt, and Horeb weſt; ſo that when the ſun riſes, the latter is covered with the ſhadow of Sinai. On Horeb there are ſprings and fruit-trees, but only rain-water on Sinai. At Horeb God appeared to Moſes in the burning-buſh. (Exod. iii. 1, 2, 3.) At the foot of this mountain Moſes ſtruck the rock, and drew water from it. (Exod. xvii. 6.) Elijah retired hither to avoid the perſecution of Jezebel. (1 Kings, xix. x.) It is frequently ſaid that God gave the law at Horeb, though in other places Sinai is named; becauſe Horeb and Sinai formed, as it were, one and the ſame mountain.

HOREHOUND, in *Botany*. See Marrubium.

Horehound, *Common white*, *Marrubium vulgare*, in the *Materia Medica*, is a plant which grows near the ſides of roads and rubbiſh, and flowers in June. The leaves have a moderately ſtrong ſmell of the aromatic kind, but not agreeable; which is improved by drying, and by keeping for ſome months is in a great part diſſipated; their taſte is very bitter, penetrating, diffuſive, and durable in the mouth. The dry herb gives out its virtue both to watery and ſpirituous menſtrua. The remaining extract, after inſpiſſating the watery infuſion, proves a ſtrong bitter, without flavour; and that of the ſpirituous infuſion is leſs in quantity, but of more penetrating bitterneſs. This plant is the πρασιον of the ancients, who have extolled it much for its efficacy in removing obſtructions of the lungs and other viſcera. It has been chiefly employed in humoural aſthmas, obſtinate coughs, and pulmonary conſumptions; inſtances alſo occur of its beneficial uſe in ſcirrhous affections of the liver, jaundice, cachexies, and menſtrual ſuppreſſions. However, though horehound poſſeſſes ſome ſhare of medicinal power, as may be inferred from its ſenſible qualities, its virtues do not appear to be clearly aſcertained, and it is now rarely preſcribed by phyſicians. A dram of the dry leaves in powder, or two or three ounces of the expreſſed juice, or an infuſion of half an handful of the freſh leaves, have been directed for a doſe. The laſt mode is uſually practiſed by the common people, who ſtill recur to it as a favourite remedy in coughs and aſthmas. Taken in conſiderable quantities, it is ſaid to looſen the body. Although, ſays Cullen, it has had the reputation of a pectoral, its virtues, in many trials, have not been obſerved, and in ſeveral caſes it has been judged hurtful. Lewis Mat. Med. Woodv. Med. Bot.

Horehound, *Baſe*, in *Botany*. See Stachys.

Horehound, *Baſtard*. See Sideritis.

Horehound, *Black*, or *Stinking*. See Ballote.

Horehound, *Stinking marſh baſtard*. See Glechoma.

Horehound, *Water*. See Lycopus.

HOREM, in *Scripture Geography*, a city of Naphtali. Joſh. xix. 38.

HORESTI, in *Ancient Geography*, a people of Scotland, mentioned by Tacitus, in Agricola's time, the inhabitants of Angus, but probably incorporated with, or ſubdued by, the Vacomagi, before Ptolemy wrote his geography.

HORGEN, in *Geography*, a town of Switzerland, in the canton of Zurich; 10 miles S.S.E. of Zurich.

HORIA, in *Entomology*, a Fabrician genus of coleopterous inſects, poſſeſſing the following character. The antennæ are moniliform; feelers four, thicker towards the tip; lip linear, and rounded at the end.

The body of the horia is long and cylindrical; the head large and inclined, ſcutel ſmall and triangular; wing-caſes coriaceous and flexile; wings membranaceous, and all the feet armed with four claws. The horiæ are allied to the cantharis, mylabris, and meloe genera, and alſo to the new genera cucujus and lymexylon. The genus was firſt eſtabliſhed in the Fabrician Mantiſſa Inſectorum for the reception of the Linnæan cantharis demeſtoides, that inſect being eſteemed diſtinct from the cantharides. His horia demeſtoides, for that is the name under which it appears in the work above mentioned, was afterwards conſigned to the lymexylons (ſee Ent. Syſt.), and the ſame generic name given to another family; that denominated horia by later writers. The genus horia, thus eſtabliſhed, contains only two ſpecies, one of which (teſtacea) Fabricius had himſelf deſcribed in his Mantiſſa, under the title of cucujus flavipes, and the other is the cucujus maculatus of profeſſor Swederus, an account of which is inſerted by that author in the Tranſactions of the Royal Society of Stockholm.

Horia is a genus adopted by Olivier, who deſcribes the ſpecies maculata. Latreille, however, ſeems to think the two Fabrician ſpecies are not generically the ſame, the head and thorax in one being much larger in proportion to the reſt of the body in the ſpecies maculata than teſtacea. Upon this opinion, ſuggeſted by Latreille, it is remarked by Olivier that we are not at preſent ſufficiently acquainted with the ſtructure of the mouth, to ſpeak with certainty, and he himſelf forbears from offering any opinion; and we further obſerve that in the lateſt publication of Latreille, he admits the firſt at leaſt of the Fabrician ſpecies under the generic name of horia. The transformations of the inſects of this family are entirely unknown.

Species.

Maculata. Yellowiſh; wing-caſes with ſeven black ſpots. Fabr. *Horia maculata*, Olivier. *Cucujus maculatus*, Swederus.

Length about an inch and a half. The ſpecies inhabits South America.

Testacea. Rufous; antennæ and legs black. Fabr. Native of Tranquebar. The poſterior thighs of the male inſect thick.

HORJA, in *Geography*, a town of Sweden, in the province of Schonen, 22 miles N. of Chriſtianſtadt.—Alſo, a town of Sweden, in Weſt Gothland; 20 miles N.N.W. of Jonkioping.

HORITES, in *Scripture Geography*, an ancient people, who dwelt in the mountains of Seir, beyond Jordan, Gen. xiv. 6. They were powerful, and had princes of their own, before Eſau conquered their country. Afterwards they and the Edomites ſeem to have formed one people. They dwelt in Arabia Petræa and Arabia Deſerta, S.E. of Judæa. Deut. ii. 1. xxiii. Judg. v. 4. The Hebrew חורים, Chorim, tranſlated Horites in Geneſis, is uſed appellatively in other paſſages of ſcripture, to denote *heroes*, or great and powerful men; and probably the Greeks derived from this term their *heroes*, as they derived *anax*, *a king*, from the ſons of Anak. See 1 Kings, xxi. 8. 11. Neh. ii. 16. iv. 14. v. 7. vi. 17. vii. 5. xiii. 17. Eccl. x. 17. Iſ. xxxiv. 21.

HORIZON, or Horison, in *Aſtronomy*, a great circle of the ſphere, dividing the world into two parts, or hemiſpheres; the one upper, and viſible; the other lower, and hid.

The word is ὁρίζων, which literally ſignifies *bounding*, or *terminating the ſight*; being formed of ὁρίζω, *termino*, *definio*, *I bound*, *I limit*; whence it is alſo called *finitor*, *finiſher*.

The horizon is either *rational* or *ſenſible*.

Horizon, *Rational*, *True*, or *Aſtronomical*, which is alſo called ſimply and abſolutely the horizon, is a great circle, whoſe plane paſſes through the centre of the earth, and whoſe poles are the zenith and nadir. It divides the ſphere into two equal parts or hemiſpheres.

Such is the circle H R (*Plate* XVI. *Aſtronomy*, *fig.* 141.) whoſe poles are the zenith and nadir; whence it follows, that the ſeveral points of the horizon are a quadrant diſtant from the zenith and nadir.

The meridian and vertical circles cut the rational horizon at right angles, and into equal parts.

Horizon, *Senſible*, *Viſible*, or *Apparent*, is a leſſer circle of the ſphere, as *h r*, which divides the viſible part of the ſphere from the inviſible, and whoſe plane touches the ſpherical ſurface of the earth.

Its poles, too, are the zenith and nadir; and conſequently, the *ſenſible* horizon is parallel to the *rational*; and it is cut at right angles, and into two equal parts, by the verticals.

The *ſenſible* horizon is divided into *eaſtern* and *weſtern*.

Horizon, *the Eaſtern*, or *Ortive*, is that part of the horizon wherein the heavenly bodies riſe.

Horizon, *the Weſtern*, or *Occidual*, is that wherein the ſtars ſet.

Horizon, in *Geography*, is a circle paſſing over the earth, and dividing the viſible part of the earth and heavens from that which is inviſible.

The altitude or elevation of any point of the ſphere, is an arc of a vertical circle, intercepted between it and the ſenſible horizon.

This is peculiarly denominated *ſenſible* or *apparent* horizon, to diſtinguiſh it from the *rational*, or true, which paſſes through the centre of the earth; as already obſerved.

Theſe two horizons, though diſtant from one another by the ſemidiameter of the earth, will appear to coincide, when continued to the ſphere of the fixed ſtars; becauſe the earth compared with this ſphere is but a point.

By *ſenſible* horizon is alſo frequently meant a circle, which determines the ſegment of the ſurface of the earth, over which the eye can reach; called alſo the *phyſical* horizon. In this ſenſe we ſay, a ſpacious horizon; a narrow, ſcanty horizon.

It is evident, that the higher the eye is, the farther is the viſible horizon extended. Thus, let H *h* r R (*Plate* I. *Geography*, *fig.* 2.) repreſent a part of the ſpherical ſurface of the earth; if the eye be at A, draw A *h* and A *r* tangents to the globe of the earth; and let one of theſe lines A *h*, the point A continuing immoveable, be carried round, and in its revolution always touch the ſurface of the earth; the point *h* will touch the viſible horizon, part of which is repreſented by the curve *h o r*. But if the eye be placed higher, as at B, the tangents B H and B R will reach farther, and the viſible horizon will be larger, *viz.* H O R. The viſible horizon is moſt accurately obſerved upon the ſea, and is, therefore, ſometimes called the *horizon of the ſea.* In obſerving this horizon, the viſual rays A *h* and A *r* will, on account of the ſpherical ſurface of the ſea, always point a little below the true ſenſible horizon S S, and conſequently below the rational horizon T T, which is parallel to it.

To find the depreſſion of the horizon of the ſea, below the true horizon, which varies with the height of the eye, and in a ſmall degree with the variation of the refractive power of the atmoſphere, ſee DEPRESSION.

The ſemidiameter of the earth, and the height of the eye being given, the extent of the viſible horizon is thus found. Let A D E (*fig.* 3.) be an arc of a great circle upon the earth, C the centre of the earth, B the eye of the obſerver, B D the height of the eye, B A and B E lines drawn from the eye, touching the ſurface of the earth at A and E, and terminating the viſible horizon: in order to find A D, draw C A, and in the triangle B A C, right-angled at A, we have C B to C A as the whole ſine or radius is to the ſine of the angle A B C, whoſe complement is the angle C, meaſured by the arc A D. *E. gr.* let D B, the height of the eye, be five feet, D C or C A, the ſemi-diameter of the earth, be 20949655 feet, and C B will be 20949660 feet: then will the logarithm of C B be to that of C A, or 7.3201769 to 7.3201768 as 10.0000000 to 9 9999999 the ſine of A B C = 89° 58′; therefore the angle C is = 2′ or 12188 feet = 2.308 miles, or two miles 532 yards, nearly. B A, or the right-lined diſtance of the fartheſt point of ſight from the eye, may eaſily be found, as the angles and other ſides are known: thus, radius or ſine of the angle A is to C B as the ſine C is to B A: or, ſince B A = $\overline{CB^2 - CA^2}|^{\frac{1}{2}} = \overline{CB + CA \times CB - CA}|^{\frac{1}{2}}$: if the logarithm of the ſum of the two given ſides be added to that of their difference, the half of theſe two logarithms will be equal to the logarithm of B A, nearly, *i. e.* $\frac{7.6222069 + 0.6989700}{2} = 4.1605884$, the logarithm of 14474 feet = B A, nearly. See DISTANCE.

The depreſſion of the horizon of the ſea, at a given height of the eye, may be thus found by calculation: for if the eye be at B, the ſenſible horizon is F G, the depreſſion is the angle F B A, which being the complement of A B C, is equal to A C D. See DEPRESSION.

The diſtance on a perfect globe, if the viſual rays came to the eye in a ſtraight line, would be as it has been now ſtated; but by means of the refraction of the atmoſphere, diſtant objects on the horizon appear higher than they really are, and may be ſeen at a greater diſtance, eſpecially on the ſea. Thus, without refraction, the moſt diſtant part of the ſea viſible to the eye at B would be A; but refraction elevates the parts of the ſea, which are farther from the eye than A, ſo that the tangent or viſual ray ſhall fall upon a more diſtant point, as H, and conſequently the extent of the viſible horizon is enlarged by refraction: for it is D H inſtead of D A; and refraction makes the angle of depreſſion leſs than it would be, *viz.* H B F, inſtead of A B F.

Father Laval, profeſſor of hydrography at Marſeilles, found, that the horizon of his obſervatory toward the ſea was never more than 15 minutes, nor leſs than 13½; that is, the arc of the circumference of the earth, intercepted between the obſervatory and the horizon, fluctuated between thoſe two quantities; whence M. Caſſini deduces, that the extent of the horizon is ſeven French leagues, of three miles each; and that the obſervatory is 175 feet high.

The height of the horizon, at the ſame place, and the ſame elevation above it, is very ſubject to vary, by means of differences in the atmoſphere, which occaſion others in the refractions.

When the ſea was full, or the north-weſt or ſouth-weſt wind blew, and the air hazy about the horizon, F. Laval always found his horizon depreſſed, or lower, *i. e.* the refraction which ſhould raiſe it in that caſe was leſs than ordinary. And yet, on the common principles, the air being now much charged with vapours, the very contrary was rather to be expected. This makes M. Caſſini ſuſpect that there is ſome other refractive matter in the atmoſphere, beſide the air itſelf.

The ſame author obſerves, that at a height ten times greater than that of F. Laval's obſervatory, he found the arc terminated by the horizon toward the ſea, 42′, without any ſenſible variation; whence he concludes, that the variations are the greater, as the height is the leſs; which may ſeem contrary to what he had aſſerted in another place, *viz.* that the variations in the apparent altitudes of bodies are greater, as theſe objects are more remote, becauſe they are ſeen through the larger quantity of air, which is liable to be varied. But the contradiction may be ſolved.

HORIZON *of the Globe.* See GLOBE.

HORIZONTAL, ſomething that relates to the horizon, or that is taken in the horizon, or on a level with the horizon.

HORIZONTAL *Dial*, is that drawn on a plane parallel to the horizon; having its gnomon, or ſtyle, elevated according to the altitude of the pole of the place it is deſigned for.

Horizontal dials are of all others the moſt ſimple and eaſy. The manner of deſcribing them, ſee under the article DIAL.

HORIZONTAL *Diſtance.* See DISTANCE.

HORIZONTAL *Line*, in *Perſpective*, is a right line drawn through the principal point, parallel to the horizon; or it is the interſection of the horizontal and perſpective planes.

Such is the line P L (*Plate* I. *Perſpective*, *fig.* 3.) paſſing through the principal point F.

HORIZONTAL *Line*, or baſe of a hill, in *Surveying*, a line drawn on the horizontal plane of the hill, or that on which it ſtands.

HORIZONTAL *Moon.* See *Apparent* MAGNITUDE.

HORIZONTAL *Parallax.* See PARALLAX.

HORIZONTAL *Plane,* is that which is parallel to the horizon of the place, or not inclined to it.

The buſineſs of levelling is, to find whether two points be in the horizontal plane; or how much the deviation is. See LEVELLING.

HORIZONTAL *Plane,* in *Perſpective.* See PLANE.

HORIRONTAL *Projection.* See PROJECTION and MAP.

HORIZONTAL *Range,* or *level range,* of a piece of ordnance, is the line it deſcribes, when directed parallel to the horizon, or horizontal line.

Dr. Halley gives two very ready theorems: the one, to find the greateſt horizontal range at 45 degrees elevation, in any ſhot made upon any inclined plane, with any elevation of the piece whatſoever; and the other, to find elevations proper to ſtrike a given object with any force, greater than what is ſufficient to reach it with the middle elevation.

1. A ſhot being made on an inclined plane; having the horizontal diſtance of the object it ſtrikes, with the elevation of the piece, and the angle at the gun between the object and the perpendicular; to find the greateſt horizontal range of that piece laden with the ſame charge; that is, half the latus rectum of all the parabolæ made with the ſame impetus. Take half the diſtance of the object from the nadir, and the difference of the given elevation from that half; ſubtract the verſed ſine of that difference from the verſed ſine of the diſtance of the object from the zenith; the difference of thoſe verſed ſines will be to the ſine of the diſtance of the object from the zenith, as the horizontal diſtance of the object ſtruck, to the greateſt range at 45 degrees.

2. Having the greateſt horizontal range of a gun, the horizontal diſtance and angle of inclination of an object to the perpendicular: to find the two elevations neceſſary to ſtrike that object. Halve the diſtance of the object from the nadir; this half is equal to the half ſum of the two elevations ſought; then ſay, as the greateſt horizontal range is to the horizontal diſtance of the object, ſo is the ſine of the angle of inclination, or diſtance of the object from the perpendicular to a fourth proportional; which fourth being ſubtracted from the verſed ſines of the diſtance of the object from the zenith, leaves the verſed ſine of half the difference of the elevations ſought; which elevations are therefore had, by adding and ſubtracting that half of the difference to and from the aforeſaid ſum. See PROJECTILE and GUNNERY.

HORIZONTAL *Refraction.* See REFRACTION.

HORIZONTAL *Roots.* See FIBROSE *roots.*

HORIZONTAL *Shelters,* among *Gardeners,* are defences, diſpoſed parallel to the horizon, for tender plants, bloſſoms, and fruits, in the ſpring, to defend them againſt blaſts, and pinching nights.

The uſual ſhelters that have obtained are baſs mats, and other warm coverings, which are rolled up in the day-time, and let down in the night. It was the reverend Mr. Lawrence who firſt propoſed horizontal ſhelters, chiefly on this principle; that moſt of our froſts and blaſts fall perpendicularly, *i. e.* the condenſed vapours, falling from the upper region, do at night form themſelves, toward the ſurface of the earth, into drops of dew, ſubject to be frozen by the coldneſs of the air.

Horizontal ſhelters are to be made by laying rows of tiles, at certain diſtances one above another, in the ſtructure of the wall, ſo as to project or hang over the plane of the wall, to carry off the dew, wet, &c. It is an inconvenience, objected to this method, that it is difficult to lead a tree rightly among the tiles, or to keep its figure duly filled up.

But the principal objection againſt theſe tiles is this; that they prevent vegetables from receiving the advantage of dews, rains, &c. in conſequence of which they become weak and languid, and at laſt entirely decay. The only ſort of horizontal ſhelters, which Mr. Miller has ever obſerved to be uſeful for fruit-trees, are made with two leaves of ſlit-deal, joined over each other, and painted. This kind of ſhelter, being fixed upon the top of the wall with pullies, to draw up and down at pleaſure, forms a ſort of pent-houſe, which being let down in great rains or cold nights, whilſt the trees are in flower, or the fruit is ſetting, proves ſerviceable; but it muſt be removed ſoon after the fruit is ſet, ſo that the trees may enjoy all the advantages of rain, dew, &c. in the ſummer, which are abſolutely neceſſary for producing healthy trees, or good fruit.

HORIZONTAL *Speculum.* One of the great inconveniencies mariners have to ſtruggle with, is the frequent want of a horizon; for though the atmoſphere may, at the height of 10 or 12 degrees and upwards, be clear enough to give a view of the ſun and other objects, yet all below that height is often ſo hazy, as to hinder a diſtinct ſight of the horizon, and conſequently to prevent obſervations from having the requiſite correctneſs. This inconveniency is removed by a horizontal ſpeculum, invented by Mr. Serſon, who was loſt in the Victory man of war, in which ſhip he was ſent out to make trial of his machine.

The principle on which this machine was conſtructed, was derived from the conſideration of a top while ſpinning: for this author obſerving that the top had a conſiderable degree of ſteadineſs in, and force to acquire, an upright motion, whether the body which ſuſtained it was in motion or at reſt: he therefore concluded, that if a circular machine, whoſe upper face was a flat poliſhed ſpeculum, was to have a ſwift circular motion communicated to it, that ſpeculum, by acquiring a horizontal ſituation, would ſhew all objects which it reflected, as much below the horizon, as they really are above it. Conſequently, if the image of the ſun, as ſeen reflected from the ſpeculum, were made to coincide with the ſun's image ſeen in a Hadley's quadrant, the angle given by the quadrant would in all caſes be double the real altitude. Mr. Serſon alſo found, that to confine the ſpeculum to one place, it was neceſſary to let the point ſpin in a cup; for the horizontality of the ſpeculum would not be altered, whatever poſition might be given to the cup; provided it touched only at the point on which it ſpun. This curious and uſeful inſtrument, as it is now improved by Mr. Smeaton, conſiſts in a well poliſhed metal ſpeculum, of about three inches and a half in diameter, incloſed within a circular rim of braſs; ſo fitted that the centre of gravity of the whole ſhall fall near the point whereon it ſpins. This is the end of a ſteel axis running through the centre of the ſpeculum, above which it finiſhes in a ſquare, for the conveniency of fitting a roller on it, by which it is ſet in motion by means of a piece of tape wound round the roller. The cup in which it ſpins is made of agate, flint, or other hard ſubſtance; and a pyramidal cover may be made to the whole, compoſed of glaſs panes: by this means an obſervation may be made with it as well covered as open, and it will thereby be prevented from tarniſhing by the moiſt air and ſpray of the ſea.

If the box be placed ſteadily, and as level as may be, after the tape is untwirled, the ſpeculum will be fit for obſervation in leſs than two minutes, and will generally continue ſo for twelve or fifteen. When it is to be uſed for a meridian obſervation, it may be convenient to know what time to ſet it up; and this may be had near enough by taking the ſun's bearing from the meridian with an azimuth compaſs, allowing for the variation; and if it has about five degrees to run before it culminates, it is then time to ſpin the ſpeculum. The obſerver is to place himſelf as near the box as he conveniently can, and look down on the ſun's image in the ſpeculum, and bring the ſun's image ſeen in the quadrant to agree with it, ſo that their centres coincide; the quadrant will then give the double altitude, without any allowance for the height of the ſhip, or the ſun's ſemi-diameter.

When the ſun is about 45° high, the obſerver muſt look through that ſight of the quadrant, which is uſed for a back obſervation: but he muſt look down on the horizontal image, or that in the ſpeculum, as if it was the back horizon; and then making the ſolar images to agree, the quadrant, according as it is numbered, will give the double altitude, or double zenith diſtance.

Theſe ſpeculums are as uſeful by night as by day; for as the images of the ſmalleſt ſtars may be ſeen in the ſpeculum, conſequently any object that can be ſeen reflected from the glaſſes of the quadrant, may be obſerved by the ſpeculum; and theſe are all the ſtars of the firſt magnitude, the planets Venus, Mars, Jupiter, Saturn, and the moon. So that by having the declinations of theſe bodies in an ephemeris, they may be uſed in obſervations as well as the ſun.

As the great diſtreſſes to which ſhips are ſometimes driven in ſeveral parts of the world, for want of a horizon to obſerve by, are by this ingenious contrivance quite removed, it is hoped the uſe of this inſtrument may become general. See HADLEY'S QUADRANT.

HORIZONTAL *Diſſepiments*, in *Natural Hiſtory*, are terms applied to the thin plates which croſs the tubes or ſtirplets of ſome corals at right angles, and connect them together, of which the tubipora muſica (figured in Ellis, tab. 27.) is an inſtance.

HORIZONTAL *Face*, in *Cryſtallography*, is uſed by Haüy in deſcribing ſecondary forms of cryſtals, the axes of which are ſuppoſed vertical, and then the faces perpendicular to theſe will be called horizontal faces, thoſe parallel to the axes being called vertical faces.

HORIZONTAL *Strata*, in *Geology*. It ſeems beſt to agree with the phenomena of the ſtrata of the earth, as well as with the opinions of the greater number and moſt able of the writers on the ſubject, to conſider the ſtrata as having been originally concentric with the earth, and entire, and, of courſe, horizontal in every part. (See CONCENTRICITY *of Strata*.) Conſiderable tracts of ſtrata are found yet in nearly a horizontal poſition, the red marle, for inſtance, on the ſouth and ſouth-weſt of Derbyſhire. (See Mr. Farey's Report to the Board of Agriculture, vol. i. p. 147.) Dr. Charles Anderſon, in his "Appendix to the Tranſlation of Werner's New Theory of Veins," p. 256, remarks, that the wideſt mineral veins occur in horizontal ſtrata, which ſeem confirmed in Derbyſhire, by the very wide veins of ſpar, void of metallic ores, which obliquely croſs Dovedale on the confines of Staffordſhire, in the fourth lime-ſtone rock, which lies horizontal, or very near it, in theſe parts.

HORLA, in *Geography*, a town of Norway, in the dioceſe of Drontheim; 48 miles W.S.W. of Romſdal.

HORLOFA, a town of Sweden, in the province of Skone; 11 miles E. of Lund.

HORMAH, or CHORMA, from חרם, ſignifying the ſame with *Anathema*, in *Scripture Geography*, a town of Paleſtine, belonging to the tribe of Simeon. It was called *Zephath* before the Hebrews called it Hormah, the occaſion of which appellation was, that the king of Arad, a Canaanite, S. of the land of promiſe, attacked the Hebrews, put them to flight, and deſpoiled them of a rich booty; upon which the Iſraelites engaged themſelves by vow to deſtroy every thing belonging to the king of Arad; a purpoſe which probably was not executed till after Joſhua entered the land of promiſe. See Joſh. xv. 30.

HORMEZION, or HORMESION, in *Natural Hiſtory*, the name of a gem deſcribed by Pliny, and ſeeming to have been a ſpecies of hyacinth. He ſays it was very bright, and of a yellowiſh-red, or flame colour, with a whitiſh caſt at the edges.

HORMILLOS, LOS, in *Geography*, a ſmall iſland in the Pacific ocean, near the coaſt of Peru. S. lat. 16° 45′.

HORMINODES, in *Natural Hiſtory*, the name of a gem deſcribed by Pliny, and others of the ancient writers. The ſtone itſelf, they tell us, was either black or white, but had in it a green ſpeck ſurrounded by a circle of a bright yellow. It ſeems to have been no other than one of the oculus belis of our jewellers.

HORMINUM, in *Botany*. See MELISSA and SALVIA.

HORMISDAS, or HORMOUZ, king of Perſia, in *Biography*, ſucceeded to the throne A.D. 579, after the death of his father, the great Choſroes. He had, during the life of his parent, obtained ſome military reputation, and while directed by the influence of prudent counſellors, he governed his dominions wiſely, but when left to himſelf he exhibited in his character and conduct a number of vices, and diſplayed the utmoſt folly and tyranny. Not fewer than 13,000 victims of all ranks are ſaid to have fallen, by his order or connivance, under the ſword of the executioner. His cruelty produced hatred, and hatred terminated in rebellion. In this ſtate of things, the khan of the Turks invaded the eaſtern provinces with a vaſt army, while the Romans renewed hoſtilities on the oppoſite ſide. The Perſian empire would have been ſubverted had it not been for the valour and talents of Bahran, or Varanes, who gave the Turks a ſignal defeat. The ſucceſsful general, in one inſtance, was himſelf defeated by the lieutenant of the emperor Maurice, and Hormiſdas had the folly and injuſtice mortally to affront him by the preſent of a diſtaff and a ſuit of women's apparel. He was bent on revenge, appeared before his troops in this garb, and found no difficulty in rouſing them to rebellion; the revolt became general, and, in the confuſion, Bindoes, a prince of the blood, who had been impriſoned by Hormiſdas, was liberated by his brother. He came to the royal palace at Cteſiphon, where the monarch was ſitting in all the pomp of royalty, and began to upbraid him for his tyranny and miſconduct. Hormiſdas ordered his attendants to ſeize him; but, overawed by the preſence of Bindoes, they were inattentive to the royal command, and ſtood patiently by and ſaw the king dragged from his throne into priſon, where he was firſt deprived of his ſight, and then of his life. Whether the king was aſſaſſinated, or died by leſs violent means, is not eaſy to aſcertain. He died in the year 599, after a reign of twenty-one years.

HORMISDAS, pope, ſon of a perſon named Julius, and a native of Fruſino, in Campania, was elected to the pontificate upon the death of pope Symmachus, in the year 514. One of the moſt prominent circumſtances that occurred during his elevation to the popedom was the death of Anaſtaſius, who was ſucceeded by Juſtin. The new emperor, though perfectly illiterate, was moſt zealouſly attached to the doctrine of the two natures. His promotion, therefore, gave the higheſt ſatiſfaction to the orthodox throughout the empire. In Conſtantinople the populace diſtinguiſhed themſelves for their zeal in the Catholic cauſe, by compelling the patriarch to receive the council of Chalcedon, and to anathematize publicly all thoſe who had rejected the decrees of the ſynod. He alſo promiſed to have what he had done confirmed by a council. A council was accordingly aſſembled, in great haſte, to gratify the impatient and riotous multitude.

The acts of this body in behalf of the Catholic faith were approved and confirmed by the emperor, who iſſued out an edict, commanding all biſhops within his dominions to conform to them, on pain of forfeiting their ſees. This decree was ſoon followed by the execution of ſuch of the Eutychians as were moſt obnoxious to the orthodox party. By theſe means of conviction, the biſhops of the Eaſt were ſpeedily brought to unite in the profeſſion of the Catholic faith, and the emperor undertook, in the next place, to unite them with their brethren in the Weſt. This ſubject occupied the pope till his death, in the year 523, after a pontificate of nine years. Many of his letters are extant. Bower.

HORMONT, in *Geography*, a town of Perſia, in the province of Lariſtan; 33 miles E.N.E. of Lar.

HORMUS, in *Ancient Muſic*, was a dance of a gay kind for girls and boys, in which the boys took the lead, putting themſelves in manly and military attitudes, the girls following in gentle and modeſt ſteps, harmonizing the two virtues of force and temperance.

The Grecian girls of good families aſſembled in troops, ornamented with noſegays, garlands, and chaplets of flowers; they afterwards went to the temples, ſinging hymns at the ſolemn feſtivals, or at the nuptials of ſome one of their companions.

The Lacedæmonian dance conſiſted of three parts, repreſenting the three ages of human life. All ſinging at the ſame time.

Age - We *have* been valiant.
Youth - We *are* ſo at preſent.
Infancy - We *ſhall* be ſo in our turn.

HORN, CORNU, a hard, callous ſubſtance, growing on the head of divers cattle, and ſerving them as weapons of offence and defence.

HORNS, in *Comparative Anatomy*. The parts which receive the name of horns are diſſimilar in form and ſtructure. They admit of being divided into four kinds at leaſt: the 1ſt are found on the *rhinoceros;* the 2d are thoſe of the *ox*, *antelope*, *goat*, and *ſheep;* the 3d belong to the *camelopard*, and the 4th to the *deer* kind.

The horns of the *rhinoceros* are thoſe moſt properly ſo called, being entirely compoſed of a horny ſubſtance. They are ſituated not upon the os frontis, but the naſal bones. They are of a pyramidal ſhape, and have no attachment to the ſkull but at the ſurface of their baſis. They appear to be made up of a number of fibres reſembling ſtrong hairs conſolidated together, and rendered ſmooth upon the ſurface, except around the baſe, where the external fibres, being broken off, preſent the appearance of a bruſh.

A number of pores, or foramina, are to be ſeen upon the baſis of the horn, into which fine vaſcular proceſſes are probably received; for, from the ſtructure of the horn of the *rhinoceros*, there is every reaſon to ſuppoſe it is formed upon pulps, in the manner of hair. (See HAIR.) Theſe foramina are the orifices of fine canals, or grooves, which paſs longitudinally throughout the horn. Cuvier ſtates, that in the *rhinoceros unicornis* there is a thick mucus interpoſed between the horn and the bone on which it is ſituated, and that in the *rhinoceros bicornis* the horns are connected with the ſkin only, and, therefore, they are in ſome degree moveable. The horns of the *rhinoceros* are not deciduous, but continue to increaſe from the root, or baſe, in proportion as they wear.

Horns of the 2d ſort are the moſt common; they belong to many of the ruminating quadrupeds, and ſome birds have ſimilar proceſſes upon their heads. They conſiſt of three parts, an oſſeous ſubſtance, a vaſcular inveſtment, and the external ſheath. The bone is the part which is firſt formed: it may be diſcovered at a very early period as a knob, or round protuberance, moveable upon the os frontis, and covered with the common integuments: as it elongates, the ſkin covering it becomes callous, and appears to wear off when the oſſeous proceſs is found to be clothed in a real caſe of horn. It then becomes fixed to the os frontis by anchyloſis. The original perioſteum of the knobs becomes thicker and ſofter, and its veſſels increaſe in ſize and number, preparatory both to the growth of the oſſeous, and the external parts of the horn between which it is interpoſed, and to both of which it ſerves as the organ of nutrition. The internal or oſſeous portion of the horn, even when fully formed, is irregular in its texture, reſembling more an oſſeous depoſit from inflammation than natural bone.

The external caſe of the horns in the *goat* and *ſheep* is ſomewhat different from that of the *ox* and *antelope:* in the latter the horny fibres appear long and continuous, and form cloſe compact layers, incaſed the one within the other; but in the *goat* and *ſheep* they are interrupted by many tranſverſe grooves, are ſhorter, and have the appearance of imbricated layers of horn.

The growth of the horny caſes is from the roots, in the manner of hairs, but it does not appear to go on continually, or without interruption; for the increaſe in each year is marked by a circular groove near the root of the horn, by which means the age of the animal can be often determined.

Horns of the 3d ſort are the ſhort ſtraight proceſſes upon the head of the *camelopard*; theſe conſiſt of bone, which is of a porous ſpongy texture; they are united to the os frontis by anchyloſis at their baſe, and the other extremities produce a regular convex knob: the ſtem or pedicle of theſe horns is merely covered by the common integuments; but the bulb on the ends ſuſtains a number of ſtrong ſhort hairs, which no doubt grow in a ſimilar manner, and are every way analogous to the fibres compoſing the horns of the *rhinoceros*.

Horns of the 4th kind are peculiar to the *deer genus*, (*cervus*): theſe are compoſed entirely of bone, and have, therefore, been deſcribed, along with the other bones, by Cuvier and other anatomiſts; we ſhall, however, find from their hiſtory, as well as ſituation, that they diſtinctly belong to that claſs of bones which enter into the compoſition of horns in general.

The horns of *deer* are ſhed and reproduced annually, their growth therefore is exceedingly rapid. Their firſt appearance is in the form of two ſmall cartilaginous knobs or buttons under the ſkin. Theſe proceed to develope their different branches or diviſions in ſucceſſion, ſtill clothed with what has been called their *velvet* coat. This integument conſiſts of the ſkin covered with a delicate ſoft hair, and the perioſteum cloſely united together. The velvet covering is extremely vaſcular; many of its veſſels acquire an extraordinary magnitude. We have ſeen them in the *ſtag* during the growth of the horn as large as the quills of a gooſe, and Cuvier ſtates them to equal the ſize of the little finger. When the horns are completely formed, the velvet coat loſes its vaſcularity, becomes inſenſible and dry, and is rubbed off by the deer, leaving the horns, in the hunters' phraſe, *burniſhed*.

The horns of *deer* acquire from friction a degree of poliſh upon the ſurface towards the top, but nearer the root, they ſtill retain the impreſſions of the large veſſels that were employed in their ſecretion. The bone of which they are compoſed is denſe and hard upon the external part, and more light and porous in the interior, although it is without cavity or medullary cells.

The original cartilaginous buttons or rudiments of the horns are ſuſtained upon eminences of the os frontis, with which they form the ſame ſort of union that exiſts with reſpect to the epiphyſis of bones, being at firſt looſe and afterwards firm. The line of their union is indicated by a circular notched protuberance upon the baſe of the horn, which is called the *burr*.

When the horns are about to be caſt, there appears, upon ſawing them in a longitudinal direction, a reddiſh mark of ſeparation between them, and the eminences of the frontal bone on which they are ſuſtained. This mark becomes more apparent, and at laſt the coheſion between the horns and the ſkull is ſo much deſtroyed, that the leaſt ſhock makes them fall after the horn is ſhed. The eminence of the os frontis preſents the appearance of a bone ſawed or broken acroſs. Its proper ſubſtance is actually expoſed, but it very ſoon becomes covered by the integuments.

The bones which conſtitute the horns of the *deer* appear to be entirely analogous to the oſſeous parts of the horns of the other ruminant quadrupeds, and only differ from them in the circumſtance of being deciduous. The horns of the *rhinoceros*, and thoſe of the *deer*, ſhould be conſidered as the two extremes in the hiſtory of theſe organs. The one wants the oſſeous baſis, the other the corneous covering. The horns of the *camelopard* and *ox*, &c. exhibit the examples of intermediate ſtructure.

The formation of the horns has been long known to be much influenced by the condition of the organs of generation. They are ſometimes peculiar to the male animal, and in the *deer* kind acquire their full bulk and complete form juſt before the ſeaſon of *rutting*, after which they are ſhed. Doctor Richard Ruſſel, in his "Economy of Nature in Diſeaſes of the Glands," relates ſome curious effects on the growth of *deer's* horns from caſtration. He caſtrated a very young *deer*, the conſequence was, the horns did not grow. He then took another *deer*, ſome months older, and caſtrated it. A little velvet bud aroſe on one ſide of the head inſtead of a horn, and an irregular velvet horn about ſix inches long grew on the other: both were cartilaginous, and neither had ſtability enough to ſtand upright. He next had a deer ſomewhat older than the laſt caſtrated, but not cut *clean*, as they term it. The event was this; he had two moſt irregular horns, that never caſt their velvet, and the left teſticle and ſpermatic cord being leaſt ſpoiled, the left horn was one-third longer than the right. Nature, not being able to carry on the growth in the regular way, threw out from the ſides of the horns ſome bony knots, from which hung ſoft penſile glands, (as he termed them,) that were covered with velvet, and reſembled bunches of grapes. Laſtly, he caſtrated two old *bucks* at the end of February, and their horns dropt off the 21ſt of March following, ſo that this event was anticipated five weeks at leaſt. Their horns were however renewed the next year, and were longer than thoſe of the other bucks of the ſame age; but the branches were leſs in length and ſize, and neither the velvet covering or the horns themſelves were ever caſt afterwards. See Economy of Nature in Acute and Chronical Diſeaſes of the Glands, by Doctor Richard Ruſſel, p. 21.

The effect of caſtration is alſo ſtrikingly to be ſeen in the different kind of horns in the *bull* and *bullock*. In the latter, the growth of the horn ſeems to be unlimited, but this depends upon the increaſe of the oſſeous part, for the corneous ſheaths are ſo thin and imperfectly formed, that they are only fit for the coarſer articles of manufacture. It is probable, that if caſtration could be performed early enough in theſe animals, it would prevent the growth of horns entirely, as in other caſes.

For the explanation of the ſtructure and mode of growth of horns, ſee the plate on *Comparative Anatomy*, including the repreſentations of *hair*, *horns*, *ſpines*, &c. *Fig.* 9. is a view of the horn of the *rhinoceros unicornis*: *a*, the body of the horn; *b*, the briſtled appearance around the root; *c*, the ſurface by which it is connected with the head covered with minute hairs. *Fig.* 10. is the button or rudiment of the *ſtag's* horn, after a fortnight or three weeks growth. *Fig.* 11. is the horn ſome weeks farther advanced with ſeveral of the branches forming. The horn is ſtill ſoft and cartilaginous, and covered by its velvet coat. *Fig.* 12. is a diſſected view of a portion of the horn in an early ſtate, to ſhew the nature of the velvet coat: *a*, the ſkin clothed with thick cloſe hair; *b*, the perioſteum thickened and vaſcular, and not cloſely adhering to the bone; *c*, *c*, ſome of the large branches of the blood-veſſels that nouriſh the horn unremoved. *Fig.* 13. is the *deer's* horn fully grown; the remains of the velvet coat are ſeen hanging in ſhreds, which the animal rubs off againſt the trees in the courſe of a day or two. *Fig.* 14. exhibits the ſocket upon the eminence of the os frontis, left by the ſeparation or caſting of the horn. *Fig.* 15. ſhews the effect produced upon the horns from imperfect caſtration in a young deer, as deſcribed and delineated by Dr. Ruſſel.

The horns of a deer are by huntſmen called his *head*. See Head.

In the Hiſtory of the French Academy of Sciences, we have an account of a bullock's horn dug out of the ground in ploughing, which had ſhot forth fibrous roots, and appeared to have grown, or vegetated after the manner of a plant.

Horns make a conſiderable article in the arts and manufactures. Bullocks' horns, ſoftened by the fire, ſerve to make lanthorns, combs, knives, ink-horns, tobacco-boxes, &c.

Horns, when properly reduced by mills or other means, are alſo found to be excellent as a manure for ſome ſorts of land, where they can be procured in ſufficient quantity for the purpoſe. They are uſed occaſionally in Hertfordſhire, and ſome of the other counties in the vicinity of the metropolis, on the tillage as well as the graſs lands, with conſiderable ſucceſs. See Horn *Shavings*.

Horns, in *Chemiſtry*: theſe have been analyzed, and found to contain a very ſmall quantity of earthy matter. Mr. Hatchett burnt 500 grains of ox horn, and the reſiduum was only 1½ grain, and not half of this was phoſphate of lime. Horns chiefly conſiſt of a membranous ſubſtance, which poſſeſſes the properties of coagulated albumen, and they probably contain a little gelatine. The horns of the hart and buck are exceptions, as they poſſeſs the properties of bone, and are compoſed of the ſame conſtituents. See Bone.

Horns, in *Rural Economy*, the well known ornaments which ſpring out from the heads of different ſorts of cattle, ſheep, and ſome other ſorts of live ſtock. It is by the horns that the breeds of many of theſe ſorts of animals are known and aſcertained. As the nature of ſuch excreſcencies muſt obviouſly be productive of much offal and waſte about the parts in which they are ſituated, it muſt of courſe be a great object of the breeder to get quit of them as much as poſſible, by the encouragement of the polled kinds, and the proper croſſing of them with the other ſorts where neceſſary. See Breed and Breeding.

Horn, in *Geography*, a town of Sweden, in Eaſt Gothland; 32 miles S. of Linkioping.

Horn, or *Hooren*, a town of Auſtria, famous for its beer made of oats, which ſupplies all the principal towns of Auſtria; 40 miles N.W. of Vienna. N. lat. 48° 37'. E. long. 15° 32'.

Horn, a town of Weſtphalia, in the county of Lippe, near which is a plain, called "Vinfeld, or the Field of Victory," ſuppoſed to be the place where Varus periſhed. N. lat. 51° 50′. E. long. 8° 52′.

Horn, an iſland on the coaſt of Weſt Florida, between Ship and Maſſacre iſlands; nearly 17 miles long, and about half a mile wide.

Horn's *Iſland*, a ſmall iſland near the coaſt of South Carolina. N. lat. 33° 7′. W. long. 79° 17′.

Horn, *Cape*, a cape on the ſouth coaſt of Terra del Fuego, or the moſt ſouthern extremity on a group of iſlands of unequal extent, lying before Naſſau bay, known by the name of Hermite iſlands, and ſituated in S. lat. 55° 58′, and W. long. 67° 46′. This cape is known at a diſtance by a high round hill over it. On the N.W. ſide are two peaked rocks like ſugar-loaves; they lie N.W. by N. and S.E. by S. by the compaſs, of each other. Some other ſtraggling low rocks lie W. of the Cape, and one S. of it; but they are all near the ſhore. From Chriſtmas Sound to Cape Horn, the courſe is E.S.E. ¼ E. diſtant 31 leagues. Between this cape and another called "Falſe or Miſtaken Cape," by Captain Cook, there ſeemed to be a paſſage directly into Naſſau-bay; ſome ſmall iſles were ſeen in the paſſage; and the coaſt, on the W. ſide, had the appearance of forming good bays or harbours. Captain Cook obſerves, though the doubling of Cape Horn is ſo much dreaded, ſo that, in the general opinion, it is more eligible to paſs through the ſtrait of Magellan, we were not once brought under our cloſe reefed topſails, after we left the ſtrait of Le Maire. He doubled the cape in 33 days, whereas it would have taken much longer time to have ſailed through the ſtrait of Magellan, with greater fatigue to the ſailors, and greater damage to the anchors, cables, ſails, and rigging of the ſhip. He thinks, that different circumſtances may at one time render it eligible to paſs through the ſtrait of Le Maire, and to keep to the eaſtward of Staten-Land at another. He alſo recommends, if neither wood nor water be wanted, to make no port and not to come near the land at all; for by keeping out at ſea, you avoid the currents, which, in his opinion, loſe their force at 30 or 36 miles from the land, and at a greater diſtance there are none.

Horn, *Cape*, (*Falſe*), a rocky point, which is the ſouthern point of the eaſternmoſt of Hermite iſles, three leagues E.N.E. from Cape Horn. Off this cape lie rocks that are white with the dung of fowls; and vaſt numbers were ſeen about them.

Horn, in the *Manege*; to give a ſtroke with the horn, is to bleed a horſe in the roof of the mouth, with the horn of a ſtag or roebuck, the tip or end of which is ſo ſharp and pointed, as to produce the ſame effect as a lancet. They ſtrike with the horn in the middle of the fourth notch or ridge of the upper jaw.

Horn is alſo a ſort of muſical inſtrument, of the wind kind; chiefly uſed in hunting, to animate and bring together the dogs and the hunters.

The horn may have all the extent of the trumpet.

The term for ſounding anciently was, wind a horn; all horns being in thoſe times compaſſed; but ſince ſtraight horns are come in faſhion, they ſay, blow a horn; and ſometimes, plainly ſound a horn.

There are various leſſons on a horn; as the recheat, double recheat, royal recheat, running or farewel recheat, &c. See Recheat.

Wind inſtruments of this name and form are as numerous and various as the animals that nature has armed with this weapon. The principal inſtrument, however, under that denomination, is the French horn, *cor de chaſſe*, hunting horn, or *corno da caccia*, which is not only uſeful in the field, but of capital utility in full pieces, ſacred and ſecular, in every orcheſtra.

The horn is a long tube, narrow at the top, and encreaſing in diameter to the end, where its mouth is very wide. It is curled up in a ring or rings, for the convenience of carriage and performance.

It has no holes or keys with which to form different tones; the whole ſcale is produced by different modifications of the breath at the mouth-piece, by the lips and tongue.

It has the ſame ſeries of notes as the trumpet, only an octave lower. All the muſic that is compoſed for it, is written in the key of C, and its pitch is altered now to any other key by crooks. At the beginning of a movement, the key is indicated by one of the ſeven letters of the gammut; as D horn, E ♭, F, or G horn, &c. Its natural ſcale is a regular ſeries of eight notes with the addition of an occaſional ſharp 4th, and the harmonics of the key below.

Attempts at *chromatic* horns have been made early in the laſt century, in Germany; the Meſſings were the firſt who pretended to perform in all keys in England, about the year 1740. Spandau, from Holland, was the firſt that was able to make the artificial notes agreeable, about 1772, and ſoon after, Ponto did wonders on this inſtrument. We have now (1803) four excellent performers on the *horn*, the Leanders and Petrides. Theſe laſt have the art of echoing paſſages in ſuch a manner as to ſeem at a great diſtance without quitting their place in the orcheſtra. It muſt, however, be diſcovered, by every diſcriminating hearer, that the factitious half notes, that are made by the hand in the mouth of the inſtrument, are ſounds of a different quality from the natural tones of the inſtrument. We have often thought that Ponto, with all his dexterity, produced ſome of theſe new notes with ſimilar difficulty, to a perſon ridden by the *night mare*, who tries to cry out, but cannot.

The Hebrews made uſe of horns, formed of rams' horns, to proclaim the jubilee; whence the name *jubilee;* which ſee.

The French horns uſed in concerts are uſually tuned an octave lower than the trumpets, to which they are cloſely allied in their principles. The whole length of tube yielding the fundamental note is often about ten feet, but it is the octave of this that performers in general are able to reach, in which the column of air in the tube vibrates in two equal parts: by blowing a little harder, the performer has it in his power to cauſe the column of air in the tube to divide itſelf into three equal parts, and whoſe vibrations conſequently have the ratio of $\frac{1}{3}$ to the fundamental, or VIII + V; a little harder blowing will occaſion three nodes or quieſcent points in the tube, and the ratio of the ſound will be $\frac{1}{4}$, or 2 VIII: harder ſtill produces $\frac{1}{5}$, or 2 VIII + III: the next note is $\frac{1}{6}$, or 2 VIII + V, a repetition of $\frac{1}{3}$ an octave higher: then $\frac{1}{7}$, which is a falſe or unnatural note, leſs than the minor 7th ($\frac{5}{9}$) by $24.9472\,\Sigma + 2\,m$, the note being 2 VIII + this falſe 7th above the fundamental tone of the inſtrument. By blowing ſtill harder each $\frac{1}{8}$th part of the tube's length yields its ſound, which has the ratio $\frac{1}{8}$, or 3 VIII: the next is $\frac{1}{9}$, and gives 3 VIII + II, or the true major tone: then $\frac{1}{10}$, or 3 VIII + III, a repetition of $\frac{1}{5}$th: then comes $\frac{1}{11}$, which is $27.25171\,\Sigma + 2\,m$ ſharper than a true minor fourth, being 3 VIII + this falſe 4th: the next note is $\frac{1}{12}$, or 3 VIII + V, another repetition of $\frac{1}{3}$: then $\frac{1}{13}$, which alſo is a falſe note, $22.58107\,\Sigma + 2\,m$ lower than a true major ſixth, or 3 VIII + this falſe VIth: then $\frac{1}{14}$, which is a repetition of the falſe 7th, or $\frac{1}{7}$, but an octave higher: then $\frac{1}{15}$, or 3 VIII + VII or true major ſeventh, $\frac{8}{15}$: then $\frac{1}{16}$, or 4 VIII: then $\frac{1}{17}$, which is a falſe minor ſecond, 3.46819 leſs than the major ſemitone, $\frac{15}{16}$, or 4 VIII + this falſe 2d: then $\frac{1}{18}$, or 4 VIII + II, a repetition of $\frac{1}{9}$ above: then $\frac{1}{19}$ which is a falſe minor third, leſs by 9.27098 Σ + *m* than the true minor third, $\frac{5}{6}$, or 4 VIII + this falſe 3d: then $\frac{1}{20}$, or 4 VIII + III a repetition of $\frac{1}{5}$, two octaves higher: then $\frac{1}{21}$, or 3 VIII + V + the falſe 7th ariſing from $\frac{1}{7}$, or another falſe minor fourth (differing 41.1989 Σ + 3 *m*, from $\frac{1}{11}$ above), which is 13.9472 Σ *m* flatter than the true 4th. Next, by increaſing the ſtrength of the blaſt, will ariſe $\frac{1}{22}$, which is a repetition of the falſe former fourth $\frac{1}{11}$ as above, an octave higher: then $\frac{1}{23}$, which is a falſe minor fifth, 9.460262 + *m* ſharper than the ſemi-diapente or flat fifth, $\frac{45}{64}$, or 4 VIII + this falſe 5th, which is 19.46026 Σ + 2 *m* ſharper than the major fourth or tritone, $\frac{32}{45}$: then $\frac{1}{24}$, or 4 VIII + V, a repetition of $\frac{1}{3}$ three octaves higher: then $\frac{1}{25}$, or 4 VIII + 2 III, the double (or ſquare) of $\frac{1}{5}$, and is 21 Σ + 2 *m* flatter than the true minor ſixth, or 4 VIII + this falſe 6th: then $\frac{1}{26}$, which is the repetition of the falſe major ſixth $\frac{1}{13}$, above: then $\frac{1}{27}$, or 3 VIII + 3 V the triple of $\frac{1}{3}$, is another falſe major ſixth (differing 23.58107 Σ + 3 *m* from $\frac{1}{27}$ above), or 4 VIII + a comma-redundant major ſixth, inſtead of the true VI: then $\frac{1}{28}$, which is a repetition of the falſe minor ſeventh or $\frac{1}{7}$ as above, but two octaves higher: then $\frac{1}{29}$, which is another falſe minor ſeventh (differing 31.0707 Σ + 3 *m* from $\frac{1}{7}$, above) and being 6.12449 Σ + *m* ſharper than the minor ſeventh, $\frac{5}{9}$, or 4 VIII + this falſe 7th: then $\frac{1}{30}$, or 4 VIII + VII, a repetition of $\frac{1}{15}$, an octave higher: and laſtly, $\frac{1}{31}$ is a falſe eighth leſs than the octave by 28.11748 Σ + 2 *m*, or 4 VIII + this imperfect VIII.

And thus we have all the natural horn or trumpet notes within the compaſs of five octaves, of which it may be obſerved, that the IIId, Vth, and VIIIth are the only *concords* found among theſe horn notes, which explains the reaſon of theſe being the only *Acute* HARMONICS (ſee that article) which accompany a note: the IId and 6th compoſed by doubling theſe harmonics, the XIIth and the XVIIth; the VIth by tripling the XIIth; and the VIIth by combining the XIIth and XVIIth together, are the only other notes of the horn or trumpet which belong to the diatonic ſcale, this dieſis-deficient minor ſixth, and the comma-redundant major ſix, being however inapplicable to practice, and all the remaining ten notes, enumerated above, are anomalous, and have the effect of highly tempered notes or wolves in the practice of diatonic muſic, which is alone uſed at this day. Compoſers for the horn contrive to introduce as few of theſe falſe notes into their pieces as poſſible, and modern horn players alſo, by introducing their hand, or a block of wood, into the broad end of the horn, contrive, by habit, to correct many of the falſe intervals when playing in concert; but this is often done at the expence of clearneſs and fulneſs of tone.

The late Mr. Charles Claggett, by combining two horns or trumpets of different pitches together, ſo that the ſame mouth-piece, by means of a ſlide, acted on by the finger, could inſtantly be made to ſound either tube, which he called his *chromatic* French-horns and trumpets, pretended, that by this means all the falſe notes were corrected: which of courſe ſuppoſed, that they were all alike tempered or defective, and that theſe lay all the ſame way, but which is far from being the caſe, as will appear from the recapitulation of the temperaments in the margin, where, however, the flat fifth is omitted, being ſharpened + 9.460 Σ, and conſequently it would be further injured by a new tube, ſharper than the firſt, either 15.836 Σ (which is the mean among the above *flat* temperaments), or by any other difference of pitch in the two tubes, which might be adopted. We ſhall reſume the curious theory of this inſtrument in the article TRUMPET.

Horns are *tuned*, or brought to the proper pitch for playing in concert with other inſtruments, by means of ſhort pieces of tube of different lengths called crooks, which are put on or taken off below the mouth-piece, ſo as to lengthen or ſhorten the entire length of the tube, according as the pitch wants lowering or raiſing.

HORN, in *Architecture*, is ſometimes uſed for volute.

HORN is ſometimes alſo uſed for the hoof of a horſe, &c.

HORNS, in *Botany*. See MEDICAGO.

HORNS *and Hedge-hog*. See MEDICAGO.

HORNS *of the Altar*. See ALTAR.

HORN, *Ammon's*. See CORNU *Ammonis*.

HORN-*beech Tree*, in *Gardening*. See CARPINUS.

HORN-*bill*, in *Ornithology*, the genus buceros of Latin authors, calao of the French. This genus is diſtinguiſhed by having the bill convex, curved, and ſharp at the edge, large, ſerrated outwardly, and furniſhed with a horny protuberance or excreſcence on the upper mandible near the baſe; the noſtrils behind the baſe of the bill; tongue ſhort, and ſharp at the point; legs ſcaly; toes, three forward and one backward, the middle one connected to the outer as far as the third joint, and to the inner as far as the firſt.

Theſe birds ſubſiſt, for the moſt part, on fruits of various kinds, generally inhabit woods, and with few exceptions are natives of the old continent.

Species.

BICORNIS. Front bony, flat, and bicornuted at the fore part. Linn. Amoen. Acad. *Hydrocorax Philippenſis*, Briſſ. *Rhinoceros avis prima varietas*, Will. *Calao*, Petiver. *Philippine horn-bill.*

Native of the Philippine iſlands; ſize of a common hen; the plumage above black, beneath white; quill-feathers with a white ſpot; tail rather long and black; tail-feathers ten in number, of which the exterior four on each ſide are white and thoſe in the middle black; legs greeniſh. A ſuppoſed variety is deſcribed in the 23d volume of the Philoſophical Tranſactions under the name of cayao vel calao, the bill of which is red, the belly black; and the back and rump brown-aſh; the legs ſcaly and reddiſh, and the claws black.

This ſpecies does not frequent watery places, but inhabits the higher lands, and is moſt common in mountainous ſituations. It feeds on fruits, among which it prefers the fig, almond, and piſtachia; theſe it ſwallows whole, and after digeſting the pulp caſts up the ſtones entire. Its voice is ſaid to reſemble the bellowing of a calf. The Indians worſhip this ſpecies as a deity.

ABYSSINICUS. Black; bony protuberance ſemicircular on the fore part; orbits, chin, and part of the throat naked, and violet brown; greater quill-feathers white. Gmel. *Grand calao d'Abyſſinia*, Buff. *Abyſſinian horn-bill.*

Reſembles a raven in ſhape, but is larger and more robuſt; it inhabits Abyſſinia, and ſubſiſts chiefly on the large green beetles which infeſt the plantations of grain. The fleſh has a fœtid odour. According to Bruce it lodges in thick trees, and is known by the name of "teir el naciba," or bird of deſtiny, on the frontiers of Sennaar. In the eaſtern parts it is called *abba gumba*, and in the weſt *erkooms*. The bill is black, edged with white, and about the baſe of the upper mandible each ſide is a tuft of briſtly feathers.

AFRICANUS. Black; protuberance on the bill like a horn, ſtraight and pointed. Gmel. &c. *Hydrocorax Africanus*, Briſſ. *Rhinoceros avis ſecunda varietas*, Will. *Brac ou calao d'Afrique*, Buff. *Trompette de Brac ou oiſeau trompette*, Labat. *African horn-bill.*

Deſcribed on the authority of Labat, who tells us it is the ſize of a turkey, with the plumage wholly black; the bill and head meaſured together were equal to eighteen inches; the figure of the bill not unlike that of the Philippine horn-bill, but having the appendage on the top of the upper mandible almoſt ſtraight at the point; the colour partly red, and partly yellow, and the edges and baſe of both mandibles black. This deſcription is adopted from father Labat by Buffon, nor does it appear to be better known ſince that time, as Sonnini, in the lateſt edition of Buffon, adds nothing to the deſcription that was previouſly given by that author. There is or was formerly a ſpecimen of this bird in the Leyden muſeum.

MALABARICUS. Black, beneath white; protuberance rounded above, acute towards the front, and reaching behind the eyes. Gmel. *Calao de Malabar*, Buff. *Pied horn-bill.*

The length two feet ſix inches, or three feet; both mandibles curved downwards, and ſharp at the tip; protuberance four inches and a half long, the greater part black, the middle, both of the protuberance and the bill, dirty yellowiſh-white; vent, quill, and outer tail-feathers tipt with white; legs ſtrong and black; claws long, hooked, and rather blunt. This ſpecies is known to devour rats, mice, and ſmall birds, raw fleſh, and vegetables; its motions are not diſſimilar to thoſe of the magpie, leaping forwards or ſideways with both legs at once; its note is various, being ſometimes hoarſe, or like the clucking of a turkey, and ſometimes weaker.

Sonnerat deſcribes a variety of this bird under the name of *Calao de la côte de Coromandel*, from its being found on the coaſt of Coromandel; the bill of this kind is curved, the protuberance egg-ſhaped; quill-feathers and tail, except the two middle feathers, which have their baſes black, are white. Dr. Latham is inclined to believe le calao des Philippines of Pl. Enl. is alſo a variety of this bird.

ALBIROSTRIS. Bill white.

This kind, which is recently deſcribed by Sonnini under the title of *le calao a bec blanc*, is nearly allied to the former ſpecies, B. malabaricus.

HYDROCORAX. Protuberance flattened forwards; the belly tawny. Gmel. *Hydrocorax*, Briſſ. *Corvi marini genus*, Cluſ. *Corvus indicus*, Bont. *Corbeau Indien*, Salerne. *Calao des Moluques*, Buff. *Indian horn-bill.*

A native of the Molucca iſles; its length two feet four inches; the protuberance cinereous, and behind whitiſh; crown blackiſh; cheeks and chin black; hind head and neck pale cheſnut; back, ſhoulders, and rump, with the wing and tail-coverts, brown; breaſt and belly blackiſh, the latter yellowiſh on the hind part; tail aſh or dirty white; legs grey brown; claws black. Feeds on the wild nutmeg, which renders its fleſh pleaſantly aromatic. This bird is frequently tamed to deſtroy rats and mice.

RHINOCEROS. Protuberance recurvate and pointed. Gmel. *Hydrocorax indicus*, Briſſ. *Rhinoceros*, Bontius. *Horned Indian raven, or rhinoceros bird*, Will. *Calao rhinoceros*, Buff. *Bec de l'oiſeau rhinoceros*, (*the bill*,) Buff.

Length three feet. This ſpecies inhabits India, preys on rats, mice, and carrion, and often follows the hunters for the entrails of their game. The bill is ten inches long, the protuberance eight inches. Inhabits India.

COLLARIS. Protuberance of the bill flat, grooved, and yellow; body and wings black; ſpace of the neck bright red; tail white. *Le calao de Waygiou*, Sonnini.

A ſpecies found in Waygiou, one of the Molucca iſles; its length is two feet and a half; and the bill ſeven inches and a half long.

VIOLACEUS. Protuberance large, and much elevated above the upper mandible, flat at the ſides, and marked with two longitudinal furrows; plumage above black, gloſſed with green, beneath white. *Le calao violet*, Levaillant.

Found in the iſle of Ceylon, and on the coaſts of Coromandel.

CORONATUS. Protuberance ſub-coronated, the bill large and yellow, or reddiſh; body above blackiſh, gloſſed with blue; abdomen and thighs yellowiſh white; tail rounded, white, and in the middle, black. *Le calao a caſque en croiſſant*, Sonnini.

Size of the rhinoceros horn-bill. This ſpecies is common in the Molucca iſles, where it inhabits great woods, is very ſavage, and feeds on carcaſes. The legs are blackiſh brown.

GALEATUS. Bill ſtraightiſh; protuberance nearly ſquare, the poſterior part rounded, the anterior flat. Gmel. *Calao a caſque rond*, Buff. *Helmet horn-bill.*

Nothing more is known of this curious ſpecies than the bill and head, the ſtructure of which ſufficiently diſtinguiſhes it, and announces it to be of a larger ſize, and poſſeſſed of greater ſtrength than the generality of other birds in the ſame tribe. Specimens of the bill are not unfrequent in muſeums, and theſe vary in length from ſix to eight inches; the colour is uſually red, and the feathers, ſometimes attached at the baſe, are black.

PANAYENSIS. Greeniſh-black, beneath reddiſh-brown; protuberance ſharp above, and flat at the ſides. Gmel. *Calao à bec cizelé de l'iſle de Panay*, Sonnerat. *Panayan horn-bill.*

Size of a raven; the bill very long, arched, brown, with tranſverſe lateral wrinkles, and longitudinal orange furrows; orbits naked and brown; irides whitiſh. The head and neck of the female is white, with a large triangular greeniſh-black ſpot; legs lead colour. Inhabits the iſle of Panay.

MANILLENSIS. Above blackiſh-brown, beneath dirty-white; bill not ſerrated; protuberance ſmall. Gmel. *Calao de Manille*, Buff. *Manilla horn-bill.*

Native of Manilla; length twenty inches. The bill rather curved and acute at the tip; head and neck white, waved with brown; temples with a black ſpot; tail with a fulvous band acroſs.

NASUTUS. Front ſmooth; tail-feathers white at the baſe and tip. Gmel. *Crotophaga*, Forſkal. *Hydrocorax ſenegalenſis melanorhynchos*, Briſſ. *Calao à bec noir du Senegal*, Buff. *Black-billed horn-bill.*

Inhabits Africa, near the river Senegal; its ſize is about that of the common wood-pecker; it feeds on fruits, and, when young, is eaſily tamed. When young the bill of this bird is black, the colour changing gradually to red as the bird grows older; the body above is ſordid greyiſh, and white beneath; claws black. The bird called by Buffon *le tock* is conſidered as a variety of this bird; its ſize is nearly the ſame, except that its length is half an inch leſs; the body varied with grey and black, beneath and collar whitiſh; head and throat lineated with black; two middle tail-feathers grey, the reſt blackiſh, with the tip white.

ALBUS. Snowy-white; bills and legs black. Gmel. *White toucan*, Hawkeſworth It. *White horn-bill*, Lath.

A ſpecies deſcribed from a ſpecimen caught between the iſland of Tinian and Pulotimoen. Size of a ſmall gooſe; the bill narrow, and bent down ; neck a foot long, and as ſmall as that of the crane.

LOBATUS. Protuberance on the bill divided tranſverſely into ſeveral lobes ; plumage black gloſſed with blue ; on the ſhoulders a red brown ſpot ; tail whitiſh. *Le calao a caſque feſtonné*, Levaillant.

Inhabits Batavia ; length thirty inches, the bill five inches long and two thick, and the margin not denticulated ; colour yellowiſh-white, with the baſe brown ; eyes ſurrounded by a naked wrinkled ſkin which covers the baſe of the mandible, and deſcends upon the throat ; the feathers on the back of the head are long ; great quill-feathers deep black. The female is rather ſmaller than the male, and has no ſpace of red brown about the ſhoulders.

OBSCURUS. Protuberance rounded above, and divided into ſeven or eight lobes ; body black ; tail-feathers white. *Buceros plicatus*, Latham. *Indian raven*, Will. *Wreathed horn-bill.*

Native of New Guinea ; the bill bent, and five or ſix inches in length. A ſuppoſed variety of this bird, found in Ceylon, has the protuberance on the bill divided into no more than five lobes.

GINGINIANUS. Bill bent, compreſſed laterally ; protuberance pointed ; body above green, beneath white ; two middle tail-feathers dirty, rufous grey, with a band of black at the end ; the reſt black rufous near the end, and white at the tip. *Buceros ginginianus*, Lath. *Le calao de Gingi*, Sonnerat. *Gingi horn-bill.*

Length two feet ; the bill from the baſe to the middle with the protuberance black, the reſt white, the edges ſerrated ; cheeks with an oval black bar under the orbits ; legs black. Inhabits the coaſt of Coromandel.

ORIENTALIS. Bill convex, above carinated, at the baſe protuberant ; orbits naked, wrinkled, and cinereous ; body blackiſh. Lath. *New Holland horn-bill.*

Inhabits New Holland ; ſize nearly as large as the jay ; the noſtrils open near the baſe of the bill.

GRISEUS. Protuberance ſloping before, abrupt behind ; body grey. Lath. *Grey horn-bill.*

Native of New Holland ; the crown black ; bill yellow, with a black ſpot at the baſe ; at the corner of each eye a tuft of briſtles, and behind a naked blue ſpot ; wing-caſes variegated with black ; quill-feathers white at the tip.

VIRIDIS. Protuberance abrupt ; body black ; wings greeniſh. Lath. *Green-winged hornbill.*

The bill in this ſpecies is yellowiſh, at the baſe of the under mandible is a whitiſh blue ſpot ; the outer tail-feathers, with the baſe of the quill-feathers, and the belly, white ; legs blueiſh. Country unknown.

CEYLONENSIS. Bill denticulated, and without protuberance, black and white ; head above, creſt, hind part of the neck, back, and coverts of the tail brown, blended with blueiſh grey. *Le calao gingala*, Levaillant.

Inhabits the iſle of Ceylon.

JAVANICUS. Bill not denticulated and without protuberance, brown with the baſe yellow ; front, head above, and long feathers of the creſt red brown ; body above and beneath black ; neck and tail white. *Le calao javan*, Levaillant.

Length thirty inches ; bill four inches and a half long ; ſkin under the eyes, and chin down to the throat, deeply wrinkled ; plumage finely gloſſed with greeniſh ; legs browniſh, and the claws yellowiſh white. This ſpecies inhabits Batavia, where it is called *jaar vogel.*

Levaillant, to whoſe coſtly work on American and Indian ornithology, we are indebted for an account of the two preceding birds, has placed them in the calao or horn-bill tribe, and in this reſpect we follow his example, though not entirely ſatisfied with ſuch an arrangement. The abſence of a protuberance on the bill in both kinds ſeem clearly to remove them from the calao tribe, notwithſtanding they accord with that genus in ſome other particulars ; in the denticulation of the bill and ſtructure of the claws *le calao gingala* agrees with the horn-bill, but le calao javan is ſtill leſs nearly allied, the bill in this kind being neither denticulated nor ſerrated at the margin, and it has only the claws of the true horn-bill to juſtify its reference to that genus. The laſt mentioned kind, from the form of the bill, appears in ſome degree connected with the corvus tribe.

HORN-*blend*, is a black or green indurated bole or clay, conſiſting of ſcaly particles, which are diſtinguiſhable from thoſe of mica, by being leſs ſhining, thicker, and rectangular. It is generally found among iron ores, and ſometimes intermixed with mica, forming a compact ſtone.

HORN-*coal*, in *Mining*, is applied to ſuch coal as dips almoſt equally on the *face* and the *end*, or in which the ſlines or lengthway joints of the coal croſs the water level diagonally, ſuch coal being often worked with ſaliant and re-entering angles, like the horn-works of a fortification, whence probably the name was derived ; ſuch are often called half-workings of coal.

HORN-*coot*, a name given by fowlers to the great horn-owl. (See STRIX *Bubo.*) A ſportſman who has got one of theſe birds, has a conſtant lure to draw together almoſt what numbers of others he pleaſes. The method of taking other birds by it is thus : the ſportſman fixes upon ſome ſingle tree which ſtands in the middle of an open field, and cutting the boughs of this into a regularity, he ſpreads nets all about it, and then places his owl within them, with a ſtring faſtened to its leg, by means of which the bird may be put in motion by the ſportſman as he ſtands at the diſtance under covert. There are to be two perches placed near one another, ſo that the owl can eaſily go from the one to the other. It is the nature of this bird to fly only by night, and therefore whenever it is ſeen by day-light, all the other birds quarrel with it, and abuſe it ; even the hawks will make at it wherever it comes in their way. The ſportſman depends upon this ; and as ſoon as he ſees any bird approach, or as ſoon as the owl, who ſees farther than he can, gives him the ſignal that ſome bird is in ſight, he pulls the ſtring, on which the owl, being diſturbed, flies from one perch to the other. This draws the ſtrange bird to her ; and flying violently at her, it is entangled in the net placed with that intent, and the ſportſman muſt immediately run up and take it out, and replace the net for the next.

HORN-*fiſh*, an Engliſh name for the fiſh which we alſo call the gar-fiſh. It is properly a ſpecies of pike or eſox. See ESOX *Belone.*

HORN-*fiſh*, in *Ichthyology*. See CORNUTUS *piſcis* and BIACULEATUS.

HORN, *harts*, *cornu cervi.* The ſcrapings or raſpings of the horn of this animal are medicinal, and uſed in decoctions, ptiſans, &c.

Hartſhorn is too expenſive an animal bone to be employed for the common preparations of ammonia, for which purpoſe the bones, that are the refuſe of the ſtreets, are uſed ; and if, after diſtillation, they be further burnt in an open fire, the reſidue in each inſtance will be the ſame, and chiefly phoſphate of lime. Hartſhorn, however, affords that particular modification of bone to which the preference is given for the purpoſes of pharmacy, and the conſumption is not ſo great, as to render the direction either too expenſive or difficult to be complied with. The phoſphate of lime left amounts to 57.5 of the bones employed; they appear alſo to contain a ſmall quantity of carbonate of lime and phoſphate of magneſia, and the remainder is animal matter, which paſſes away in various compound gaſſes under the circumſtances in which it is in this preparation directed to be placed.

Hartſhorn *jelly* is nutritive and ſtrengthening, and is ſometimes given in diarrhœas; but a decoction of burnt hartſhorn in water is more frequently uſed for this purpoſe, and is called hartſhorn *drink*. See JELLY.

The coal of hartſhorn, by being calcined with a long continued and ſtrong fire, is changed into a very white earth, called hartſhorn calcined to whiteneſs, or *cornu uſtum*. This earth is emplowed in medicine as an abſorbent, and adminiſtered in dyſenteries and labour-pains, which are ſuppoſed to be cauſed by acrid and ill-digeſted matters. This earth levigated is the baſis of Sydenham's white decoction, which is commonly preſcribed in theſe diſeaſes.

The white decoction or mixture of burnt hartſhorn is prepared by boiling down two ounces of hartſhorn burnt and prepared, and one ounce of Acacia gum, in three pints of water to two, conſtantly ſtirring, and afterwards ſtraining it. As burnt hartſhorn conſiſts entirely of phoſphate of lime, which is inſoluble in the preparation above directed: it is only brought into the ſtate of a very fine powder, and is kept mechanically ſuſpended in a mucilaginous liquor, on which account the gum is an uſeful addition, to the original formula in Bates's Pharmacopœia, which contains none. This is retained in the laſt pharmacopœia as one of thoſe eſtabliſhed forms which are in uſe with many practitioners. The *pulvis opiatus*, or powder of burnt hartſhorn with opium, is a compoſition of hard opium powdered, a drachm, hartſhorn burnt and prepared, an ounce, and cochineal powdered, a drachm, well mixed. This preparation affords a convenient mode of exhibiting ſmall quantities of opium, ten grains containing one of the opium. As the article by which it was divided is of no other conſequence, a ſmall quantity of cochineal is added to give it a colour, and thus to prevent it from being accidentally confounded with any of the numerous white powders kept in the ſhops. The former name of *pulvis opiatus* was particularly exceptionable, as ſometimes in the abbreviation of preſcriptions it was found to be miſtaken for *pulvis opii*. The ſalt of hartſhorn is a great ſudorific, and given in fevers with ſucceſs; and hartſhorn alſo yields, by diſtillation, a very penetrative volatile ſpirit.

HORN-*hipped*. A horſe is ſaid to be ſo, when the tops of the two haunch-bones appear too high.

HORN-*owl*. See STRIX *bubo*.

HORN *of Plenty*. See CORNUCOPIA.

HORN *with horn*, or HORN *under horn* (*cornutum cum cornuto*), is when there is common *per cauſe de vicinage*, intercommoning of horned beaſts. See COMMON and INTERCOMMONING.

HORNS *of Inſects*. See FEELERS and ENTOMOLOGY.

HORN *Shavings*, a term applied to the ſmall thin pieces of waſte horny matters which are formed in the preparation of different articles from this ſubſtance, in extenſive manufactories. Every ſort of refuſe material of this deſcription has been found beneficial upon land, when employed in the way of a manure, either as a top-dreſſing, or when turned into the ſoil. In the county of Hereford they make uſe of two deſcriptions of theſe ſorts of matters, the *ſmall* ſort, or turner's ſhavings, and the *large*, or refuſe pieces of horn, which are cut off by the ſaw or any other tool. The farmers purchaſe the firſt of theſe ſorts in London, at from about thirteen or fourteen ſhillings the quarter, or ten-buſhel ſack ſtuffed quite full, moſtly weighing about two hundred and a half. They are generally employed exactly in the ſame way and proportions per acre as the clippings of farriers, only they do not ſtand in need of being pricked into the ſoil when uſed upon the ſurface of the tillage lands. And it is the uſual practice with the large ſort to have them ploughed into the ſoil, about three months before the time of ſowing either wheat or barley. Shavings of theſe kinds are found, from actual trials, to anſwer well in moſt ſoils and ſeaſons, with the exception of ſuch as are very dry and parching, when they are ſaid not to work, by the farmers. The ſmall ſhavings ſhould be preferred, as being the moſt uſeful and advantageous when employed in the way of a dreſſing for land. See MANURE.

HORN, *Staining of*. See BONES, DYEING, IVORY, TORTOISE-*ſhell*, and WOOD.

HORNS, *Foſſil*, in *Natural Hiſtory*. The horns of animals, accompanied by their ſkulls and bones, or otherwiſe, are frequently found in the earth, but always in looſe and alluvial earth, or in caverns and fiſſures, near the ſurface, as was remarked by Dr. Woodward, and has been confirmed by ſubſequent obſervers. The foſſil horns which have been deſcribed are ſaid to be thoſe of

A Calf, deſcribed to be conic, crooked, with a pith and ray, not unlike a young budded horn. Dr. Grew's Rarities, p. 274.

Deer.—Horns reſembling thoſe of deer are ſaid to be frequently met with in the peat-pits in Ireland. Phil. Tranſ. Abr. by Lowth, vol. ii. p. 434.

Some of theſe are very large, and have very broad palms above the brow antlers, which are palmated alſo. (Gent. Mag. vol. lxxv. p. 1133.) Parts of a large deer's horn were found in a pit at Hutton Hill, in Somerſetſhire. (Jones's Phyſ. Diſq. p. 425.) In digging the Weſt India Docks, in the Iſle of Dogs, and alſo in the peat-pits near Newbury, in Berkſhire, deer's horns are met with. Parkinſon's Org. Remains, p. 95 and 98.

Horns of the fallow-deer are ſaid to have been found by M. Cuvier, in looſe ſtrata, in France. Phil. Mag. vol. xxxv. p. 387.

The horns of the mooſe-deer, very large, were dug up in 1781, at Beline, N. E. of Carrick, in Kilkenny, in Ireland, which are preſerved in Beſborough hall, near that place. (Tigh's Survey of Kilkenny, p. 98.) Others are mentioned by Mr. Jameſon, Shetland Iſles, p. 158. Horns of this kind of deer are alſo mentioned to be found in America. Jones's Phyſ. Diſq. p. 420.

The horns of a rein-deer were preſerved at Cheſter, which were dug up there. Benj. Martin's Nat. Hiſt. vol. ii. p. 245.

Elks.—Among the remains of ruminating animals in looſe ſtrata, M. Cuvier found the horns of a ſpecies of elk, now extinct. In Hardwick hall, near Alt Hacknal, in Derbyſhire, horns of a prodigious ſize are preſerved, which, it is ſaid, were found many years ago in peat, in the northern parts of Derbyſhire, and to be thoſe of an elk.

Goats.—The horns of goats are among thoſe enumerated by M. Cuvier, as found in the recent alluvial ſoils near Paris. Phil. Mag. vol. xxxv. p. 387.

Oxen.—The horns of different ſpecies of theſe, are ſtated by M. Cuvier to be found in the looſe recent ſoils of ſome vallies in France.

Stags.—The head and horns of a ſtag were dug up at Wattington park, in Oxfordſhire, mentioned by Dr. Plott, Staffordſhire, p. 161. In the peat of Plumſtead level, by the Thames. (Phil. Tranſ. vol. l. p. 109.) They have alſo occurred to M. Cuvier in the alluvia and putrid marſhes of France. Phil. Mag. vol. xxxv. p. 387.

In the accumulations of tufa from the petrifying ſprings at Matlock Bath, and formerly at Alport, near Yolgrave, in Derbyſhire, very large ſtags' horns have been found at different periods.

Urus.—The horns of this large animal have been found in the peat-pits of Ireland (Jameſon's Shetland Iſles, p. 158.); and according to M. Cuvier they have been found in the valley of the Somme, alſo in Suabia, Pruſſia, Italy, and England. Phil. Mag. vol. xxxv. p. 387.

The horns of very large unknown animals were found at St. Martins, near Commercy (Nicholſon's Journ. 8vo. xxiii. p. 159.); and others with the teeth and ſkull at Oelte, near Ninava, in Ruſſia, (Phil. Mag. vol. xxxv. p. 318.) At Hopton hall, in Derbyſhire, the pith of a horn $5\frac{1}{2}$ inches diameter above the bone of the ſkull, and 16 inches long, is preſerved, which was found near Padley hall, 15 feet beneath the ſurface, in the deep-cutting at the W. end of the Butterly tunnel for the Cromford canal.

We have ſelected the above, in order to ſhew, that the horns found in a foſſil ſtate in the earth are of various kinds; and from the details which are preſerved reſpecting them, there ſeems no reaſon to think that horned animals exiſted, while the ſtrata were depoſiting, the moſt ancient of theſe horns being found in the alluvial flats or marſhes in the vallies, and no inconſiderable portion of them in peat, which proves their recent origin.

Sometimes extraneous foſſils have been called horns, which have no pretenſions to that character, an inſtance of which occurs in Derbyſhire, where the quarrymen and colliers find a conical and ſlightly bent foſſil, which they ſay is the bony core of a horn, or harn as they pronounce it; theſe are found, with ſome variations in the ſhape, in grit ſtone at Overton quarry, at Wickerſley quarry in Yorkſhire, in Wingeſworth, Cheſterfield, Alfreton, &c. In bind at Bretby, &c. Mr. William Martin, in his Petrificata Derbienſia, plate 8, ſhews them to be of vegetable origin, and denominates them Graminis ſulcatus. Some have ſuppoſed theſe horn-like foſſils to be a kind of cupped coralloid.

HORNS *of the uterus*, two proceſſes ariſing from the ſides of the fund. See UTERUS.

HORN-*work*, in *Fortification*, a ſort of out-work, advancing toward the field, to cover and defend a curtin, baſtion, or other place, ſuſpected to be weaker than the reſt: as alſo to poſſeſs a height, &c.

It conſiſts of a front and two branches; the front is made into two demi-baſtions and a curtin; its ſides, or flanks, are uſually parallel; though ſometimes they approach or contract towards the place, forming what they call a *queue d'yronde*, or ſwallow's tail.

When the flanks are too long, they ſometimes make epaulements to flank them. The parts of the horn-work next the country are to be defended by a parapet.

For the conſtruction of horn-works, produce the capital of the ravelin beyond the ſaliant angle A (*Plate* VI. *Fortification*, *fig.* 1.) to the diſtance A B, of about eighty toiſes; draw D B E at right angles to A B, in which take B D, B E, each equal to fifty-five toiſes; and on the outward ſide D E, trace the front of a polygon in the ſame manner as that of the body of the place, making the perpendicular B F eighteen toiſes, and the faces thirty. The branches D *a*, E *b*, of the horn-work, when produced, terminate on the faces of the baſtions, within five toiſes of the ſhoulders. The ditch of the horn-work is twelve toiſes, and its counterſcarp parallel to the branches, and in the front terminates at the ſhoulders. The capital of the ravelin before the front of the horn-work is thirty-five toiſes, and the faces terminate on the ſhoulders, or rather two or three toiſes beyond them; and the ditch before the ravelin is eight toiſes. There are ſometimes made retrenchments within the horn-work, ſuch as S, S; which are conſtructed by erecting perpendiculars to the faces of the ravelins, within twenty-five toiſes of their extremities. This retrenchment, like all others, has a parapet turfed only with a beam of eight feet before it, and likewiſe a ditch from three to five toiſes broad. When a horn-work is made before the baſtion, the diſtance of the front from the ſaliant angle of the baſtion is a hundred toiſes; and the branches terminate on the faces of the adjacent ravelins within five toiſes from their extremities; the reſt of the conſtruction is as before.

Two horn-works joined together make a crown-work, which is conſtructed by deſcribing from the ſaliant angle A (*fig.* 2.) of the ravelin, as a centre, an arc of a circle, with a radius of about 120 toiſes, cutting the capital of the ravelin produced at C; from the point C ſet off the chords C B, C F, each equal to a hundred and ten toiſes, and on each of theſe conſtruct the front of a polygon of the ſame dimenſions, as in the horn-work, that is, the perpendicular ſhould be eighteen toiſes, the faces thirty, and the branches terminate on the faces of the baſtions, within twenty-five toiſes of the ſhoulders. The ditch is twelve toiſes; the capital of the ravelin thirty-five, and its ditch eight. When the crown-work is made before the baſtion, the arc is deſcribed from the ſaliant angle of the baſtion with a radius of a hundred and twenty toiſes, and the branches terminate on the faces of the adjacent ravelins, within twenty-five toiſes of their extremities, &c. as before. Muller's Elem. of Fortif. p. 39, &c. See *Military* CONSTRUCTION.

HORN-*wrack*, in *Zoology*, the trivial Engliſh name of the genus Fluſtra, a tribe of Vermes in the Zoophyta order. See FLUSTRA.

HORNAGIUM, HORNAGE, in our ancient *Law Books*, ſeems to import the ſame with *horngeld*.

HORNBEAM, in *Botany*, &c. See CARPINUS.

HORNBEAM, in *Rural Economy*, a name commonly given to a tree of the deciduous ſort, which is occaſionally grown as timber, being made uſe of in turnery, as well as for the cogs of mills and other ſimilar purpoſes.

There are two ſpecies of this tree, the *common hornbeam*, and the *hop hornbeam*, but which afford the following varieties; as the *eaſtern hornbeam*, the *flowering hornbeam*, the *Virginia flowering hop hornbeam*, and the *American hornbeam*. The common hornbeam is a native of Europe and America, while the hop hornbeam is met with in Italy and Virginia. The common ſort grows to the largeſt ſize, and is probably the beſt kind for the purpoſes of timber.

All the ſorts of theſe trees are capable of being increaſed, either by ſeeds or from layers. The layer method ſucceeds at almoſt any ſeaſon of the year. The ſeeds may be ſown in the ſeed part of the nurſery any time in the autumn, after they have been a little dried upon a mat, or otherwiſe, for the purpoſe. This is beſt done in narrow beds to the depth of about two inches, which ſhould be kept perfectly clean and free from weeds. They muſt continue in theſe beds until the ſecond ſpring, when they come up, and require to be kept free from every ſort of annoyance, being watered in very hot ſeaſons. About the third ſpring the young plants may be ſet out in the nurſery ground, where they may continue until they are wanted for being planted as ſtandard trees.

In the layer method, a few good plants ſhould be provided for the purpoſe of ſtools; which in the Eaſtern ſort may be planted at a yard diſtant, but with the others a yard and a half, or even two yards apart. As ſoon as theſe plants have made a proper number of ſhoots, they ſhould be layered or laid down into the ground in the autumnal months, and in the courſe of about a twelvemonth they will generally become well rooted; at which time, or in the winter or early ſpring, they may be taken off, and planted out in the nurſery manner, taking care to bruſh up or mould the ſtool well, for the future produce of young ſhoots for additional ſupplies of layers. The plants in the nurſery ſhould be allowed about a foot or a foot and a half, the rows being at the diſtance of two feet. They may continue in this ſituation until they are wanted for being finally planted out, being carefully weeded, and the mould well ſtirred about them in the rows, by winter digging, &c. The Virginia hornbeam frequently throws out two leading ſhoots, which afterwards contend for the maſtery. Where this is the caſe, that which appears the beſt ſhould be preſerved, the other being removed by means of the knife. If this be neglected the trees will be liable to become forked in moſt caſes, and of courſe leſs valuable to the planter.

The common hornbeam affords excellent ſtakes and edders, beſides fuel wood and charcoal. The timber produced by it may be ranked with thoſe of the beech and ſycamore; but its principal ſuperiority conſiſts in its excellence for the purpoſes of *ſcreen fences* for ſheltering gardens, nurſery grounds, and different ſorts of young plantations, from the ſeverity of bad ſeaſons, &c. It bears cutting in, pruning, and clipping, extremely well, and, from its retaining its leaves during the winter ſeaſon, becomes particularly cloſe and impenetrable to the winds and ſtorms, keeping up a very ſteady temperature of the atmoſphere about the plants which it ſhelters. On this account alſo, it is found beneficial to be planted in mixture, or in occaſional rows, with many tender ſorts of trees in high expoſed aſpects, in the manner of the birch, to which it is preferable, as affording greater warmth in the winter. This ſort of tree ſhould perhaps be more attended to as a nurſe for young expoſed plantations of trees, than has hitherto been the caſe, in conſequence of its qualities in this way being but imperfectly known.

The eaſtern ſort is particularly valuable where low hedges of deciduous trees are wanted, from its inferior growth, and the ſmallneſs of its leaves and cloſeneſs of the branches.

HORNBEAM *Pollengers*, a denomination given by ſome to trees of this ſpecies, which have been lopped, and are of about twenty years growth. See TREE.

HORNBEAM *Wood, Petrified*, in *Natural Hiſtory*. In a breach of the embankments or tide walls of the Thames, which happened near Purfleet, as deſcribed in the Philoſophical Tranſactions, N° 325, the Rev. W. Derham diſtinguiſhed hornbeam among the other woods and vegetable products found a great way below the ſurface of the marſhes; belonging, however, to the claſs of recent or peat foſſils, and not to thoſe of the ſtrata.

HORNBERG, in *Geography*, a town of Wurtemberg, in the Schwartzwalde; 38 miles S.W. of Stuttgard.—Alſo, a town of Germany, belonging to the Teutonic knights, near the Neckar; 18 miles E. of Heidelberg.

HORNBURG, a town of Weſtphalia, in the principality of Halberſtadt, on the Ilſe; 10 miles N.E. of Goſlar.

HORNBY, is a ſmall market town and chapelry in the pariſh of Melling, hundred of Lonſdale, Lancaſhire, England. It is ſeated on the eaſtern banks of the river Loyne or Lune, over which is a ſtone bridge of three arches. A religious hoſpital, or priory, was eſtabliſhed here at an early period; and at the diſſolution was granted to the Monteagle family, who alſo poſſeſſed an old baronial manſion called Hornby caſtle, which ſtands on an eminence about half a mile from the town. According to Camden, this "noble caſtle was founded by N. de Mont Begon, and owned by the Harringtons and Stanleys, barons of Monteagle, deſcended from Thomas Stanley, firſt earl of Derby." It has a large ſquare tower, and a lofty round one; has lately undergone a complete repair; and is now the property and reſidence of John Marſden, eſq. Hornby church, which is ſubordinate to that of Melling, is a neat edifice, and diſtinguiſhed by an octagonal tower. Hornby is diſtant from London 248 miles, and contained, according to the late return, 87 houſes, and 414 inhabitants. The cotton manufactures conſtitute the chief buſineſs of the place. A fair or market is held every alternate Tueſday for cattle; here is alſo an annual fair of two days. Beauties of England and Wales, vol. ix.

HORNCASTLE, a market town and pariſh in a ſoke of that name, in Lindſey diviſion of the county of Lincoln, England, is ſituated upon an angular piece of land formed by a ſmall rivulet named Waring, and the river Bain. The latter is navigable from the Witham to this place. The town derives its name from *horn* or *hyrn*, in Saxon ſignifying an angle or corner, and a caſtle or fortification. Traces of the caſtle are yet viſible; the whole formerly occupied an area of nearly twenty acres. The foundations ſhew that it was in the form of a parallelogram, and incloſed a great part of the preſent town. Numbers of Roman coins have been found here; and there lately exiſted, near the river, one of thoſe intricate circles called Julian's bower. Theſe circumſtances, and its ſituation on a lingula or tongue of land, induced Stukely to conſider it a Roman ſtation, and to place here the Bannovallum of the geographer Ravennas. The town was incorporated in the time of queen Elizabeth, with the privilege of holding a weekly market on Saturdays, and an annual fair; two other fairs have been ſince eſtabliſhed. A conſiderable trade in leather is carried on here; the place being principally occupied by tanners. Horncaſtle is 139 miles N. from London, and in the year 1801 contained 403 houſes, and 2015 inhabitants. Here are a good grammar, and a charity ſchool. Beauties of England and Wales, vol. ix.

HORNCASTLE *Navigation*, was made, in purſuance of acts of parliament obtained in 1792 and 1800, from the old Witham river near Tatterſhall, to the bridge in the town of Horncaſtle, a diſtance of about 11 miles, in the county of Lincoln. See CANAL.

HORNE, in *Biography*. See HOORNE.

HORNE, GEORGE, a prelate in the church of England, was born at Otham, near Maidſtone, in Kent, in the year 1730. His father, who was rector of Otham, undertook the early claſſical education of his ſon, for which he was perfectly qualified. When he was thirteen years of age, he was ſent to the Maidſtone grammar ſchool, then under the care of a maſter eminent for his knowledge in ancient literature. A Maidſtone ſcholarſhip in the univerſity of Oxford becoming vacant, he was, when he was about fifteen years of age, ſent to the Univerſity college, where he applied himſelf with ſo much diligence and aſſiduity to his ſtudies, that he was greatly diſtinguiſhed among his contemporaries, as well for his attainments in polite literature, as for that ſpecies of knowledge which is ſubſervient to the illuſtration of the ſcriptures. In the year 1749 he took his degree of B.A.; and in the following year, upon a vacancy taking place in a Kentiſh fellowſhip at Magdalen college, he was elected to fill it. Mr. Horne at this time had been deeply tinctured with the myſteries of Hutchinſonianiſm, which led him to do his utmoſt to bring diſcredit on the ſyſtem of the immortal ſir Iſaac Newton. What he publiſhed on this occaſion, without his name, he was ſincerely aſhamed of afterwards, and never ſuffered it to be reprinted. In 1752 he took his degree of M.A., and in the ſame year engaged in a controverſy on the ſubject of the Cherubim, in the Gentleman's Magazine. His object was to prove that the Cherubims were a repreſentation of the Trinity. In 1753 he entered into orders, and ſoon obtained a high reputation as a preacher, on account of the excellence of his compoſitions and the gracefulneſs of his elocution. In 1764 Mr. Horne was admitted to the degree of doctor in divinity, and in 1768 he was elected preſident of Magdalen college, and in 1771 he was appointed chaplain in ordinary to his majeſty, in which capacity he officiated for ten years. In the following year, when a number of the clergy were about to apply to parliament for relief in the matter of ſubſcription to the liturgy and the thirty-nine articles of the church of England, Dr. Horne did all in his power to defeat their object. He was next appointed vice-chancellor of the Univerſity, in which ſtation he continued till the month of October 1780, and no one ever preſided in that poſt with a more conſcientious attention to its duties, or a greater ſhare of popularity. The vice-chancellorſhip introduced him to the acquaintance of lord North, by whoſe intereſt he was promoted to the deanery of Canterbury, in which ſituation he acquired the reſpect and eſteem of all, and frequently gratified the public by preaching in the cathedral. In 1790 Dr. Horne was advanced to the epiſcopal ſee, by being nominated to the biſhopric of Norwich, ſoon after which he reſigned his preſidentſhip of Magdalen college. At this period, his health, which had ever been delicate, was in a precarious ſtate, and after he had taken poſſeſſion of his ſee, his friends ſaw, with extreme ſorrow and regret, that he declined very rapidly. From two viſits to Bath he received ſenſible benefit, and in the autumn of 1791 he ſet out on a third viſit to the ſame place. During his journey he was attacked with a paralytic ſtroke, from the effects of which he never recovered, though he was enabled to reach to the end of his journey. After lingering for ſome weeks, during which he retained the full poſſeſſion of his faculties, and diſplayed exemplary patience, compoſure, and cheerfulneſs; he died at Bath on the 17th of January 1792, in the ſixty-ſecond year of his age, animated by thoſe hopes which ſpring from the conſciouſneſs of a well ſpent life, and the promiſes of the goſpel. The works of this excellent divine were numerous, and many of them valuable. His principal piece was a "Commentary on the Book of Pſalms, &c." which made its appearance in 1776, in two volumes 4to. It was his favourite performance, and had coſt him the beſt part of twenty years in the compoſition. Dr. Horne was diſtinguiſhed by a conſiderable ſhare of various learning, which he conſecrated, according to his judgment, to the cauſe of truth, and the beſt intereſts of mankind. His virtue was ſincere and ardent, and his life exemplarily virtuous.

HORNECK, Anthony, a learned divine, was born in the lower Palatinate in 1641, and educated at Heidelberg under Spanheim. At the age of 19 he came to England, and entered himſelf of Queen's college, Oxford, of which he was afterwards the chaplain. He was now incorporated M. A. from the univerſity of Wittemberg, and not long afterwards obtained the vicarage of Allhallows in Oxford. He retained this living only about two years, and in 1665 removed into the family of the duke of Albemarle, in the capacity of tutor to his ſon lord Torrington. The duke preſented him with the rectory of Doulton in Devon, to which was afterwards added a prebend in the cathedral of Exeter. In 1671 he became preacher at the Savoy, and in 1693 prebendary of Weſtminſter. He was alſo honoured with the appointment of chaplain to king William and queen Mary. He died in 1696 of a ſevere attack of the ſtone in the fifty-ſixth year of his age. He was a man of very extenſive learning, and particularly converſant in the Oriental languages, eccleſiaſtical hiſtory, controverſial theology, and caſuiſtry. Few men, it is ſaid, were ſo frequently conſulted in caſes of conſcience as Dr. Horneck. He was author of ſeveral pious and learned works, which are as judicious as they are learned, and which are ſtill known and admired. Gen. Biog.

HORNED, a term employed, in ſome diſtricts, to ſignify the goring or wounding with the horns of cattle.

Horned *Cattle*, a term often made uſe of by farmers to ſignify neat-cattle, or animals of the low kind.

Horned *Poppy*. See Poppy.

HORNET, Crabro, in *Entomology*, a ſpecies of *Veſpa*; which ſee.

Hornet-*fly*, a very large two-winged fly, which has the ſhape and colours of the hornet, and is, at firſt ſight, ſcarce to be diſtinguiſhed from it. The principal colour of the body of this fly is yellow; but it has two long and large black lines placed tranſverſely on it, and has a black corcelet, and a yellow head.

Theſe lay, at a proper ſeaſon, a large number of oblong white eggs, which hatch into large and long worms, whoſe chief food is the worms and nymphs of the humble bees. The worm of this fly is continually found in the neſts of theſe bees, where it never meddles either with the wax or honey, but preys only on the young offspring of the creature.

HORNGELD ſignifies a tax, within the foreſt, to be paid for the feeding of horned beaſts. See Geld.

"Quietum eſſe omni collectione in foreſta de beſtiis cornutis, &c. Et ſint quieti de omnibus geldis, et danegeldis, et wodgeldis, et ſenegeldis, et horngeldis, &c."

To be free of horngeld, is a privilege granted by the king to ſuch as he thinks good.

HORNHEAD, in *Geography*, a promontory on the north-weſtern coaſt of Ireland, at the extremity of a ſmall peninſula, called by the ſame name, in the county of Donegal, province of Ulſter. It is ſuppoſed to have been mentioned by Ptolemy under the name of Boreum promontorium, and it is ſtill ſometimes called North Cape. Hornhead is the weſtern point of Sheephaven, a harbour little frequented, and was probably called from two ſharp ſummits like horns at the top of the cliff, which are a good object for the mariner. The peninſula of Hornhead has been pointed out by Dr. Hamilton (Tranſactions of the Iriſh Academy) as exhibiting the effects of drifting ſands in a ſtriking manner. In 1787 it contained veſtiges of encloſures ſo ſmall and ſo numerous, as to mark the former reſidence of a number of families in a ſpot which then exhibited nothing but

> " ——— A deſert, ſalt and bare
> The haunt of ſeals, and orcs, and ſeamews' clang."

Near Hornhead is a curious and frightful phenomenon called M'Swine's gun. By decompoſition of part of the rock, the waves have perforated a cave many yards in diameter, which extends about ſixty feet into a rock, making part of the mainland, and nearly horizontal with the level of the ſea at high and low water-marks. When the wind blows due north and the tide is half in, this gun of M'Swine's is ſeen to ſpout ſea-water far higher than the eye can reach, with an exploſion that may be heard at a diſtance of above twenty miles. Hornhead is near Dunfanaghy. N. lat. 55° 13'. W. long. 7° 51'.

HORNING, in *Scots Law*, a writ iſſuing from the ſignet, in his majeſty's name, at the inſtance of a creditor againſt his debtor, commanding him to pay or perform within a certain time, under pain of being declared a rebel, and by a caption put in priſon.

HORNIUS, George, in *Biography*, was born in the Palatinate about the cloſe of the 17th century. He was in high eſtimation as a writer of hiſtory; and his chief works are "Hiſtoria Eccleſiaſtica ad ann. 1666:" "De originibus Americanis:" "Geographia vetus et nova:" "Hiſtoria Philoſophica." He viſited England, and attached himſelf to the Preſbyterian party; and on his return he occupied the chair of hiſtory in the univerſities of Harderwyck and Leyden. He died in 1750.

HORNOS, in *Geography*, a town of Sweden, in Weſt Bothnia; 15 miles S. W. of Umea.

HORNOY, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Amiens; 15 miles W.S.W. of Amiens. The place contains 1190, and the canton 10,661 inhabitants, on a territory of 152¼ kiliometres, in 24 communes.

HORNPIPE, in *Muſic*, the name of an inſtrument, and of a tune. The hornpipe air, ſo frequently danced by our ſailors and active ſtage dancers, is perhaps the only national tune, or melody, which we can call our own. It is of high antiquity, and can be traced to the ancient Britons, perhaps before the invaſion of Julius Cæſar, or the Saxons. The inſtrument, in our old authors, is called the *Pip-corn*, or pipe of Cornwall. And when the Britons were driven by the Saxons, ſome into Wales, ſome into Armorica, or Britanny, and ſome into Cornwall, we may ſuppoſe the inſtrument and tune to have been preſerved in the laſt mentioned province, and to have retained its name. The inſtrument called a hornpipe, though unknown in England, was a few years ago ſo common in Wales, according to the late honourable Danes Barrington, that even the ſhepherd's boys uſed to play on it. It conſiſts, ſays Mr. B., of a wooden pipe with holes, at proportional diſtances, and a horn at each end, the one to receive the wind from the mouth of the player, and the other to produce the ſounds, as modulated by the performer. Mr. Barrington communicated to the Antiquarian Society a delineation and deſcription of this ruſtic inſtrument (Archæologia, vol. iii. p. 33.), and conjectured that it originally gave the name to the tune called a hornpipe.

Chaucer, in his Romant of the Roſe, fol. 135, mentions this inſtrument.

Controue he would, and foule faile
With Hornpipes of Cornewaile.

Mr. Jones, in one of his tracts, ſays that the pibgorn, or hornpipe, is peculiar to the iſle of Angleſea; but the word, in old Engliſh and French authors, implies a tune as well as an inſtrument.

The Lancaſhire hornpipes, Cheſhire rounds, and ſome of our very old country dances, are, perhaps, genuine Engliſh melodies; but melody, till after the invention of the opera at Florence in 1600, was little cultivated in any part of Europe. We had very good church muſic in our cathedrals, from the time of Tallis and Bird, to the arrival of Handel, in 1710; but being ſet to Engliſh words, it never reached the continent.

HORNSEY, or Hornsea, in *Geography*, a market town and pariſh in the diviſion of Holderneſs, and Eaſt Riding of the county of York, England, is ſeated near a mire, or lake, on the coaſt. Of this town our topographers have not recorded any hiſtorical particulars. Gough, in his addition to Camden's Britannia, merely ſtates that Hornſey "has a high ſpire, formerly a ſea mark, but now much ruined through the inability of the inhabitants to repair it. An inſcription in the town ſays that it was once ten miles from the ſea; though at preſent only one. Not many years ago a ſmall ſtreet, called Hornſey-bek, adjoined to the ſea, was waſhed away, except two or three houſes; and about Skipſie, a few miles north of Hornſey, they have a tradition of a town called Hide being devoured by the ſea. Amber is found in large maſſes on this coaſt." There are a ſmall weekly market on Mondays, and two annual fairs. In 1800 the town conſiſted of 133 houſes, and 533 inhabitants.

Hornsey, a pariſh in the hundred of Oſſulſton, and county of Middleſex, England. The village is five miles north of Holborn-bars, London, and is pleaſantly ſeated in a valley, through which the New river is conducted in its artificial channel. The pariſh conſiſts of about 2200 acres of land, of which 50 only are arable, about 120 wood, 150 waſte, or common, and the remainder meadow and paſture. Beſides the village of Hornſey, the following hamlets are within the pariſh: Crouch-end, Muſwell-hill, Stroud-green, and a conſiderable part of Highgate.

The manor of Hornſey has belonged, from time immemorial, to the biſhops of London, who had formerly a palace here. This is ſuppoſed to have ſtood on a ſpot called Lodge-hill, where are ſtill to be ſeen the remains of a moat. In this pariſh, between Highgate and Hornſey, the New river was formerly carried over a valley by a wooden aqueduct, 178 yards in length. A more laſting channel, of clay, &c. was made for it in 1776. Many of the houſes here are the reſidences of London merchants. From the boldneſs of the hills around, and finely wooded character of the country, Hornſey may be juſtly conſidered a very delightful and eligible place of reſidence. In the year 1801, the pariſh was eſtimated to contain 458 houſes, and 2716 inhabitants. Lyſons's Environs of London, 4to. vol. iii.

HORNSTANDET, a peninſula on the coaſt of Sweden, in the gulf of Bothnia, about 30 miles in circumference. N. lat. 61° 39'. E. long. 17° 16'.

HORNSTEDTIA, in *Botany*, is a genus named by Retzius in honour of Dr. Clas Frederick Hornſtedt, lecturer on natural hiſtory and medicine at Lincopin in Sweden, and Fellow of the Academy of Sciences at Stockholm. Retz. Obſ. faſc. 6. 18. Willd. Sp. Pl. v. 1. 9.—Claſs and order, *Monandria Monogynia*. Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juſſ.

Gen. Ch. *Infloreſcence* a conical ſpike, gaping at the top, nearly radical. *Calyx* two-cleft. Tube of the *corolla* long, thread-ſhaped; limb double; the exterior coat three-cleft; nectary tubular. *Capſule* of three cells, oblong. *Retzius.*

Obſ. The two ſpecies of this genus deſcribed by Retzius, and which we are about to mention, are ſuppoſed by Dr. Smith to belong to different genera. He imagines that *H. Scyphus* is an *Amomum*, and *H. Leonurus*, a *Kempferia*, but as this is merely a ſuggeſtion, we retain the genus till we learn further particulars concerning it from Dr. Roxburgh.

1. *H. Scyphus*, Retz. Willd. n. 1. (Amomum ſcyphiferum; Retz. Obſ. faſc. 3. 63.)—"Leaves downy underneath."—A native of groves at the foot of the mountains near Malacca.—*Roots* ſpreading horizontally. *Stems* about eight feet high, very tough. *Leaves* ſeſſile, ſmooth above. *Flowers* in cluſters, monopetalous, of a fine ſcarlet colour. *Seeds* numerous, club-ſhaped, oblong. The plant has ſcarcely any ſmell.

2. *H. Leonurus*. Retz. Willd. n. 2. (Amomum Leonurus; Retz. Obſ. faſc. 3. 69.)—"Leaves ſmooth, fringed."—Found in the thickeſt receſſes of groves in Malacca.—*Root* ſimple, having a hot aromatic taſte. *Stems* ſimple, ſolitary, nodding towards the top. *Leaves* alternate, fringed, with golden-coloured briſtles, ſmooth on both ſides, ſmelling like cloves. *Calyx* ſhorter than the tube of the flower. *Germen* inferior, nearly globoſe, ſmall, covered with dark ferruginous hairs. *Seeds* numerous.

Neither of theſe ſpecies appear to have been known to Rumphius, Rheede, Plunkenet, nor any other author who has applied himſelf to the deſcription of Oriental plants.

HORNSTEIN, in *Natural Hiſtory*, is a name given in Germany to the ſiliceous ſtone, called in England chertz, or chert.

HORNY Excrescences, in *Surgery*. It appears, from ſome inſtances on record, that excreſcences of a horny nature have been met with on the human ſubject, which, although they have much excited the attention of naturaliſts, muſt be conſidered entirely as *Luſus Naturæ*.

A remarkable caſe of this deſcription is that of a female who had two complete horns growing on her head, one of which, with the portrait of the woman, is preſerved in the Britiſh Muſeum, and the other at Oxford.

A far more recent inſtance, however, has been obligingly communicated to us by Dr. William Roots of Kingſton on Thames, who, in February 1811, amputated an excreſcence of this ſort, exactly reſembling a *ram's horn*, from the head of a man, between fifty and ſixty years of age, a drawing of which in its growing ſtate, as well as the horn itſelf, he has preſented to the collection of Mr. Aſtley Cooper.

The account given by Dr. Roots of this extraordinary caſe is, that John Kennedy, a gardener at Thames Ditton in Surrey, in the year 1796 had a tumour growing on the ſuperior part of the occiput, which was taken off with the knife by the doctor's father in about three years from its commencement. Soon after its removal, a horny ſubſtance began to make its appearance on the ſame place, which continued growing for four years, till it accidentally fell off in a moſt unexpected manner, being at that time not more than three inches in length; and it ſhould be obſerved, that the ſurface of the part it grew from, on its dropping off, was perfectly ſmooth, without any the ſlighteſt hemorrhage, and reſembling the ſuperficies of the ſtag's head, when his horns have recently dropped. In a ſhort time after a new horny ſprout ſhot forth, which, as it grew, took on the exact form and crooked figure of a *ram's horn*, and having increaſed during ſeven years, without any diſpoſition to fall off, to the great inconvenience of the poor man, he conſented at length to its removal; in the performance of which, from the parts underneath being very vaſcular, a conſiderable hemorrhage enſued.

Now it appears probable from this, ſays the doctor, that the horn, had it been ſuffered to remain longer on the head, would have attained a much larger ſize, nature having in a playful mood moſt abundantly ſupplied it with veſſels for that purpoſe. Its having likewiſe been ſhed in the former inſtance *without bleeding*, induces Dr. Roots to conclude, that as the ſources of its nutriment continued open, it had not arrived at that ſtate of perfection, when the gradual cloſing of the veſſels would occaſion a ſpontaneous removal, without any hemorrhage taking place, as is always obſerved to be the caſe with animals who drop their horns at regular and ſtated periods. Some years ſince we ſaw ſir James Earle remove a complete horn, about three inches long, from the ſcrotum of a patient in St. Bartholomew's hoſpital. We have always believed, that all horny excreſcences, which are occaſionally formed on the ſkin of the human ſubject, are originally encyſted tumours, the cyſt of which very curiouſly aſſumes the power of ſecreting horn, inſtead of fat, a pappy ſubſtance, or a fluid like honey, as commonly happens in the reſpective caſes of ſteatoma, atheroma, and meliceris. We think that the particulars of the caſe, communicated to us by Dr. Roots, tend to corroborate this opinion, ſince, before any horn made its appearance, there was a tumour, and, after the firſt horn dropped off, a ſurface, which was quite ſmooth, which did not bleed at all, and which, in fact, muſt have been a part of the cyſt, preſented itſelf to notice. In the caſe of the horn, which was cut off in St. Bartholomew's hoſpital, the truth of the preceding ſentiment, concerning the formation of horny excreſcences on the human race, was almoſt demonſtrated. There was at firſt a tumour, which burſt, and from the inſide of which the horny matter was gradually protruded.

HORNYGOLD's Keys, in *Geography*, iſlets and rocks on the Spaniſh main, near the Moſquito ſhore. N. lat. 15° 40'. W. long. 82° 18'.

HOROCHAW, a town of Poland, in Volhynia; 32 miles S.W. of Lucko.

HORODEK, a town of Ruſſian Lithuania, in the palatinate of Wilna; 68 miles S.E. of Wilna.—Alſo, a town in the palatinate of Brzeſc; 38 miles S.E. of Brzeſc.

HORODICTIC Quadrant. See Quadrant.

HORODISCZE, in *Geography*, a town of Auſtrian Poland, in Galicia; 60 miles E. of Lemberg.—Alſo, a town of Lithuania, in the palatinate of Minſk; eight miles S.E. of Minſk.

HORODLA, a town of Auſtrian Poland, in the palatinate of Belcz, on the Bug; 32 miles N. of Belcz.

HOROGRAPHY, compounded of ὥρα, *hour*, and γράφω, *I write*, the art of making or conſtructing dials; called alſo, *horologiography*, *gnomonica*, *ſciatherica*, *photoſciatherica*, &c. See Dialling.

HOROLOGIOGRAPHY, the art of making or conſtructing dials. See Dialling.

HOROLOGIUM, Ὡρολογιον, compoſed of ὥρα, *hora*, *time*, *hour*, and λογος, *ſpeech*, *diſcourſe*, a common name, among ancient writers, for any inſtrument or machine for meaſuring the hours. See Chronometer.

Such are our clocks, watches, ſun-dials, &c. See Clock, Watch, Dial, and Clepsydra.

Modern inventions, and gradual improvements, have given birth to ſome new terms that come properly under this head, and annexed new meanings to others totally different to what they had originally. All chronometers that announced the hour by ſtriking on a bell were called clocks; thus, we read of pocket-clocks, though nothing could ſeem more abſurd than to ſuppoſe that a clock, according to the modern idea, ſhould be carried in the pocket. In like manner, all clocks that did not ſtrike the hour were called watches, or timepieces; and the different parts of a ſtriking clock were diſtinguiſhed by the watch-part, and the clock-part; the former, meaning that part which meaſures the time, and the latter, the part which proclaims the hours. In the report of ſir

Iſaac Newton to the houſe of commons, anno 1713, relative to the longitude act, he ſtates the difficulties of aſcertaining the longitude by means of a watch; yet it is obvious, from ſeveral circumſtances, that his remarks were directly to be underſtood of a time-piece regulated by a pendulum; for his objections are founded on the known properties of the pendulum, ſome of which differ eſſentially from the properties of the balance and ſpring. It is alſo to be remembered, that all the attempts of Huygens for finding the longitude were by means of pendulum clocks, that did not ſtrike the hour, and conſequently, according to the language of the times, were called watches. At this time ſuch machines for meaſuring time as are fixed in their place, are called clocks if they ſtrike the hour; if they do not ſtrike the hour, they are called time-pieces; and when conſtructed with more care, for a more accurate meaſure of time, they are called regulators. Some artiſts of late have affected to call ſuch watches as were conſtructed for aſtronomical and nautical obſervations, by the name of *time-pieces*, probably to intimate that they poſſeſs the advantages of thoſe conſtructed with a pendulum.

Mr. John Harriſon firſt gave the name of time-keeper to his watch, for the performance of which he received from parliament the ſum of twenty thouſand pounds. See Chronometer.

Horologium, *Horologion*, is alſo a name the Greeks give to their liturgy, or breviary; becauſe it contains the daily hours, or the ſeveral offices to be rehearſed each day.

The Greeks call it ωρολογιον, which anſwers to what in Latin and Engliſh we call *diurnum*, or *diurnal*.

The ωρολογιον is the breviary of the Greeks.

HOROMETRY, the art of meaſuring or dividing the hours, and keeping an account of time.

HOROPTER, in *Optics*, is a right line drawn through the point where the two optic axes meet, parallel to that which joins the centres of the two eyes, or the two pupils.

Such is the line A B (*Plate* VI. *Optics*, *fig.* 3.) drawn through the point of concourſe C, of the optic axes of the eyes D and E, parallel to H I, which joins the centres of the eyes H and I.

It is called horopter; as being found, by experience, to be the limit of diſtinct viſion.

The horopter has ſeveral properties in optics, which are deſcribed at large in Aguillonius, Opt. lib. ii. Diſſ. 10.

Horopter, *Plane of the*. See Plane *of the Horopter*.

HOROSCOPE, in *Aſtrology*, the degree or point of the heavens riſing above the eaſtern point of the horizon, at any given time when a prediction is to be made of a future event; as, the fortune of a perſon then born, the ſucceſs of a deſign then laid, the weather, &c.

The word is compoſed of ὡρα, *hora*, *hour*, and the verb σκεπτομαι, *ſpecto*, *conſidero*, *I conſider*. The Latins call it *cardo orientalis*; ſometimes *aſcendens*. See Ascendant.

They were formerly ſo infatuated with horoſcopes, that Albertus Magnus, Cardan, and others, are ſaid to have had the temerity to draw that of Jeſus Chriſt.

Horoscope is alſo uſed for a ſcheme, or figure, of the twelve houſes; *i. e.* the twelve ſigns of the zodiac, wherein is marked the diſpoſition of the heavens for any given time.

Thus we ſay, to draw a horoſcope, conſtruct a horoſcope, &c. We call it, more peculiarly, *calculating* a nativity, when the life and fortune of a perſon are the ſubject of the prediction; for they draw horoſcopes of cities, great enterprizes, &c. See House.

Horoscope, *Lunar*, is the point which the moon iſſues out of, when the ſun is in the aſcending point of the eaſt. This is alſo called the *part of fortune*.

Horoscope is alſo a mathematical inſtrument, in manner of a planiſphere; but now diſuſed.

It was invented by J. Paduanus, who compoſed a ſpecial treatiſe thereon.

HORPS, Le, in *Geography*, a town of France, in the department of Mayenne, and chief place of a canton, in the diſtrict of Mayenne; eight miles N. W. of Vilaine. The place contains 1618, and the canton 8793 inhabitants, on a territory of 182½ kiliometres, in 10 communes.

HORREA, in *Roman Antiquity*, were public magazines of corn and ſalt meat, out of which the ſoldiers were furniſhed on their march in the military roads of the empire.

Horrea was alſo the name which they gave to their *granaries*; which ſee.

HORREBOW, Peter, in *Biography*, a celebrated Daniſh aſtronomer, and profeſſor of that ſcience at Copenhagen, was born at Lægſted, in Jutland. He ſtudied at Aalburg under very unfavourable circumſtances, being obliged, at the ſame period, to ſubmit to various kinds of labour. In 1714, he was appointed profeſſor of mathematics at Copenhagen, and in 1725 he was elected a member of the Daniſh Academy of Sciences. He died in 1764, at the great age of 85. He was author of many works connected with his favourite purſuits, among which were "Copernicus Triumphans, ſive de Parallaxi Orbis Annui;" "The Elements of Aſtronomy;" "The Elements of Mathematics;" &c. &c.

HORROR, Horrour, ſtrictly ſignifies ſuch an exceſs of fear as makes a perſon tremble. It is a compound of admiration and fear, not without an occaſional mixture of pleaſure, from which, when predominant, it is denominated a pleaſing horror.

Horror, in *Medicine*, nearly ſynonimous with *rigor*, is uſed to denote that tranſient *ſhivering*, accompanied by a ſenſation of cold, which is among the firſt ſymptoms of febrile diſeaſes in general. Hippocrates conſiders it as expreſſive of a leſſer degree of ſhivering than the term *rigor*; but a few perſons, he ſays, employ the word to denote a greater degree of chillineſs than rigour. (See his Treatiſe de Flatibus.) Celſus conſiders the *horror* as a general ſhaking, ſuch as often occurs in the outſet of a paroxyſm of ague. "Frigus voco, ubi extremæ partes membrorum inalgeſcunt; *horrorem* ubi totum corpus intremit." (De Medicina, lib. iii. cap. 3.) Sennertus again tells us, that horror implies an agitation of ſkin only; while rigor ſignifies a ſhaking of the whole body; and this appears to be the ſenſe in which the two words are moſt commonly underſtood. Sennerti Opera, vol. i. p. 387.

Horror *of a Vacuum*, was an imaginary principle among the ancient philoſophers, to which they aſcribed the aſcent of water in pumps, and other ſimilar phenomena, which are now known to be occaſioned by the weight of the air. See Air.

HORROX, Jeremiah, in *Biography*, was born at Toxteth, near Liverpool, about the year 1619. He received his academical education at Emanuel college, Cambridge, after which he began to apply himſelf very diligently to the ſtudy of aſtronomy, but as at this period his circumſtances were very moderate, and as he could have no acceſs neither to books nor inſtruments, he was unable to make any conſiderable progreſs in the purſuit. About the year 1636 he became acquainted with Mr. Crabtree, whoſe genius led him to the ſame kind of ſtudies, and with whom Mr. Horrox correſponded, and they both communicated their diſcoveries to Mr. Foſter, profeſſor of Greſham college. Mr. Horrox, by the countenance and aſſiſtance of his friend, purſued his ſtudies with renewed vigour, and having procured inſtruments and the neceſſary books for the purpoſe, applied with great diligence to the making of obſervations. Scarcely, however, had he entered the career of diſcoveries, before he was ſuddenly cut off by death in the year 1640-1, when he was only 22 years of age. Of the loſs which the world ſuſtained by this melancholy event, ſome notion may be formed from the writings which he left behind him. He had juſt completed his "Venus in Sole viſa," which was publiſhed at Dantzic in 1662, by Hevelius, together with his own "Mercurius in Sole viſus," and illuſtrated with that aſtronomer's notes. The remaining papers of our young aſtronomer were digeſted and publiſhed by Dr. Wallis in 1673, under the title of "Opera Poſthuma," &c. Two things are deſerving notice, and will perpetuate the memory of this very extraordinary young man. He was the firſt who ever predicted or even ſaw with a ſcientific eye the paſſage of Venus over the ſun's diſk, and though he was not aware of the great uſe that was to be made of it, in diſcovering the parallax and diſtance of the ſun and planets, yet he made from it many uſeful obſervations and improvements on the theory of Venus. The other circumſtance was his new theory of lunar motion, which Newton himſelf made the ground-work of his aſtronomy relating to the moon; ever ſpeaking of Mr. Horrox as a genius of the firſt rank.

HORS *de ſon fee*, q. d. *out of his fee*, in *Law*, is an exception to avoid an action brought for rent, or other ſervice, iſſuing out of certain lands, by him that pretends to be the lord. For if the defendant can prove the land to be without the compaſs of his fee, the action fails.

HORSE, in *Zoology*. See EQUUS.

The horſe makes the ſubject of a very extenſive art called horſemanſhip, conſiſting of divers ſubordinate arts or branches.

From the ſame beaſt alſo ariſe the profeſſions of chivalry, knighthood, &c.

Authors are divided as to the time when men firſt began to mount horſes. The ſcholiaſt of Euripides, and Euſtathius on the ſecond book of the Iliad, ſpeak as if the ancients had been unacquainted with the uſe of ſaddle horſes, and had only uſed them to draw chariots, &c. They add, that courſes on horſe-back were not introduced at the olympic games before the fifteenth Olympiad. But this can ſcarcely be; becauſe the centaurs, to whom the invention is attributed, lived long before that time. Beſides, Homer, though he mentions only chariots in his account of the ſiege of Troy, ſpeaks of riding ſo familiarly in ſome parts of his Iliad and Odyſſey, that it muſt have been practiſed among the Greeks before he compoſed either of theſe poems. In the fifteenth book of the Iliad he repreſents the ſtrength and activity of Ajax, when he fought in defence of the Grecian ſhips that were attacked by the Trojans, and leaped from one ſhip to another, by the readineſs and addreſs with which a ſkilful horſeman would vault from the back of one horſe to that of another; and his ability to defend many ſhips at once by that of the accompliſhed rider, who is capable of managing and controuling ſeveral horſes at the ſame time. This compariſon proves, not only that riding was commonly known at the time when Homer wrote, but that it muſt have been ſtudied and cultivated with great care and attention. In the fifth book of the Odyſſey, the poet compares Ulyſſes, ſhipwrecked and ſitting aſtride a plank which was floating on the waves, to a man beſtriding a horſe, and keeping his ſeat in ſpite of the motions which the animal could make. Herodotus, in Thalia, ſpeaks of hunting on horſeback, as an exerciſe practiſed in the time of Darius; in Melpomene, likewiſe, he ſays, the Amazons hunted on horſe-back, with their huſbands, the Sarmatians. Xenophon ſays, that Cyrus hunted on horſe-back, when he had a mind to exerciſe himſelf and his horſes.

It appears, likewiſe, from Pauſanias, that there were horſe-courſes even in the time of Hercules, the inſtitutor of the Olympic games.

It alſo appears, from the moſt ancient hiſtory extant, *viz.* the hiſtory of the Bible, that the horſe was made ſubſervient to the will of man in the earlieſt times, and therefore the uſe of this animal is probably almoſt coeval with mankind. See Gen. ch. xlvii. 17. Job, xxxix. 18, 19. Gen. l. 9. Exodus, xiv. 9.

From the two laſt cited paſſages, in which chariots and horſemen are named together, it appears probable, that the uſe of chariots and the art of riding were introduced about the ſame time, the latter being a little prior to the former; and Egypt ſeems to have been the country to which mankind are indebted for the equeſtrian art, though the preciſe period of time in which it was firſt practiſed cannot ſo eaſily be aſcertained. It is certain, however, that when Jacob came into Egypt, he found the inhabitants perfectly acquainted with the horſe, and uſing it in its two-fold capacity of carrying and drawing. From hence it was conveyed to the Ethiopians, Arabs, Indians, Perſians, Parthians, Armenians, Scythians, &c.

The Ethiopians, as we learn from Herodotus, poſſeſſed a breed of horſes, and were acquainted with the art of riding; accordingly he deſcribes them as a nation of cavalry that attended Xerxes in his expedition againſt Greece. We have no information with reſpect to the equeſtrian hiſtory of the ancient Arabs; although in later times they have become ſo famous for riding, that they may be ſtiled a nation of horſemen. The inhabitants of India were accuſtomed to uſe horſes from the earlieſt times; and Herodotus aſſerts, that the troops of this country, which attended Xerxes in his famous march againſt Greece, fought on horſe-back, as well as employed chariots in war.

The Perſian horſes have been always famous for beauty, vigour, fire, and other eminent qualities, and ſo celebrated for ſpeed, that their very name in the language of the country ſignifies what may be rendered by the word "windfoot," a term emphatically expreſſive of their ſwiftneſs. The ancient Perſians were ſo fond of them, and thought the act of managing them ſo becoming and neceſſary a duty, that they taught their children to ride at the age of five years, as Herodotus relates. Vegetius deſcribes the horſes of this country as moſt valuable for the ſaddle, being ſafe, gentle, and very agreeable to the rider, conſtituting a very conſiderable part of the revenue of their owners, and very profitable to thoſe who could ſupport a fine breed. Their paces were ſingularly graceful, as well as ſoft and eaſy, ſo as to relieve rather than fatigue the rider. They were quick and nimble, but ſubject to tire on a long march or journey; inclined to obſtinacy and rebellion, unleſs curbed and ſubdued by diſcipline and exerciſe; but notwithſtanding their heat and anger, not difficult to be pacified; always maintaining a graceful carriage, arching their neck, and bending it to ſuch a degree as almoſt to make their chins lean upon their breaſts; while their pace was ſomething between a gallop and amble, anſwering to what the French call "aubin," and we a "rack."

The Parthians were very eminent for the ſkill with which they managed their horſes, and their manner of fighting upon them; and they are deſcribed as having ſuch dexterity and ſuppleneſs of body, and ſuch a command over their horſes, that they could turn themſelves round upon their backs with ſo much eaſe and readineſs as to be able to draw their bows with the ſureſt aim, and wound their enemies even whilſt they were flying from them; this manner of fighting being peculiar to them. The name of "Parthus" is derived from a Chaldean word which ſignifies "horſeman." Their horſes are ſaid to have been very active and eaſy in their paces, which they formed by attention and practice. (See PACE.) The Parthian horſes were very hardy, and inured to incredible fatigue, as well as to travel a long time without food or water. Thus Propertius deſcribes them (lib. iv. eleg. 3.).

> "Quot ſine aqua Parthus millia currat equus."
>
> "How many miles can run the Parthian horſe,
> Nor quench his thirſt in the fatiguing courſe?"

Armenia boaſted of its breed of horſes, hardly inferior to the Perſian race. Vegetius ſpoke of the inhabitants of this country as being very careful in trimming and adjuſting the manes of their horſes. (See MANE.) Niſæa, a diſtrict of Armenia, boaſted of its breed of very large and beautiful horſes. The chariot of Xerxes, in his famous expedition, was drawn by horſes of that country, which were choſen for the taſk, becauſe they were the nobleſt that could be procured. Media was alſo a region eminent for its horſes, and from its ſituation and properties, produced them of equal value with the neighbouring countries. The Scythians were proverbially famous, as in the terms "Scytha equum," for their attention to horſes. They preferred mares to horſes, conceiving them to be more capable of ſervice, and accordingly uſed them more than horſes in war. The Sarmatians, both Aſiatic and European, were diſtinguiſhed horſemen, and had large breeds of horſes. They uſed horſes not only for riding, but offered them in ſacrifice to their gods; they alſo eat their fleſh, and drank their blood. Lucan (l. iii.) and Virgil (Georg. iii.) record this cuſtom. The horſes of Cappadocia have been much celebrated both by hiſtorians and poets, both for their ſwiftneſs and the ſtatelineſs of their action. The inhabitants of Numidia, Mauritania, Naſamonia, Maſſilia, and other adjacent tracts of the ſame region, are highly commended for having had horſes of great ſwiftneſs and vigour; and more particularly for their peculiar manner of riding them, without a bridle or ſaddle, uſing a wand only, or ſwitch to guide and command them. This breed of horſes ſeems to have been the ſame with that of Lybia, or, as that tract is now called, Barbary, famous for its excellent horſes, which were extolled for their ſpeed, wind, and patience of fatigue. Xenophon, Oppian, and Ælian concur in commending them. The method abovementioned, of guiding and governing horſes by a wand or ſwitch, is ſtill practiſed in Barbary by the lower ſort of people. The horſes of Libya are proverbially ſwift.

The colonies which came from Phœnicia and Egypt, in which equitation flouriſhed, brought this art with them, and eſtabliſhed it in Greece long before the ſiege of Troy, and with the art tranſplanted thither the horſe, which was not originally a native of Greece. The Theſſalian horſes were the moſt famous of ancient Greece, and valued and admired not only by the inhabitants of that country, but by the moſt judicious and experienced of other nations. Mycenæ, Epirus, Lacedæmon, Argolis, Arcadia, Magneſia, Dalmatia, Ionia, the iſland Scyros, the Attic territories, and Elis in particular, were all diſtinguiſhed by their breeds of horſes. From Greece the art of horſemanſhip was tranſmitted to the Romans, who cultivated it with ſuch diligence and zeal, that they were ſoon able to excel their maſters. The Etrurian or Tuſcan breed is praiſed by Oppian; and the Sardinian, Corſican, and Venetian horſes are much commended. Agragas in Sicily, and Calpe and Tarteſſus in Spain, are alſo celebrated for their horſes. Aſturia, Gallicia, and Andaluſia, then called Bœtica, were known to produce the fineſt of their kind. The horſes of Gaul were alſo held in conſiderable eſteem by the Romans; and they were not unacquainted with thoſe of the Germans, which are mentioned by Cæſar and Tacitus, but by the latter not much to their credit. Like the Armenians, the Romans always turned the mane on the right ſide. Varro and Virgil direct it to be ſo placed.

It was the cuſtom, among the ancients, to impreſs ſome mark on their horſes: the moſt common were, Σ, *ſigma*, a K, *kappa*, and a bullock's head. Hence thoſe marked with Σ's were called Σαμφοραι; thoſe with a K, Καππατιαι; and thoſe with a bull's head, Βουκεφαλοι, *Bucephali*. It is, however, more probable that the famous horſe Bucephalus owes his appellation to the reſemblance which his head bore to that of a bull, and not to the impreſſion of one which was burnt into his fleſh, and was a mark in no wiſe peculiar to him, but common to all horſes, ſo that he could not have been particularly diſtinguiſhed by it. And Aulus Gellius, lib. v. cap. 2. expreſsly tells us that this was the fact; and that the head exactly reſembled, in ſhape and figure, the head of a bull. This mark was ſtamped on the horſe's buttocks and his harneſs, as appears from the ſcholiaſt in Ariſtophanes's Clouds, Heſychius, &c.

The Romans, as well as the Greeks, diſtinguiſhed their horſes by certain marks, which were burnt into the fleſh: theſe were the initial letters of the owners' names, figures of animals and other devices, by which the horſes were known and appropriated, frauds prevented, and the breeds and pedigrees, of which they were very careful, preſerved and diſtinguiſhed. It was alſo uſual for them to give names to their horſes, expreſſive of their country, qualities, or colour. The Sybarites, a voluptuous people of Calabria, are ſaid to have taught the horſes in their troops to move or dance in exact time to the ſounds of muſical inſtruments.

In modern times, Arabia is moſt diſtinguiſhed for the excellence of its horſes, and the addreſs of its inhabitants in riding them.

The Arabians breed their horſes for ſale, and there is a conſiderable revenue ariſing from thoſe that are ſent out of the country, the tax being about ten pounds ſterling for each horſe. Theſe people are ſcrupulouſly exact in preſerving the pedigree of their horſes for ſeveral ages; ſo that they know their parentage, alliances, and genealogy, diſtinguiſhing each breed by different appellations, and dividing the whole kind into three claſſes. The firſt claſs is called *noble*, being the moſt pure and ancient, without any mixture, on the ſide of the ſires or dams. The ſecond claſs is compoſed of horſes, whoſe race, though ancient, has been mixed with plebeian blood, either on the male or female ſide, which nevertheleſs is deemed noble, but miſallied. The laſt claſs comprehends the common horſes, which are ſold at a low price; but the two former ſorts are extremely dear, the loweſt-priced mares of the firſt claſs being worth five hundred French crowns, and ſome fetching even four, five, or ſix thouſand livres.

When a ſtallion covers a mare among the Arabs, both being of equal quality, witneſſes are called to be preſent on the occaſion, who ſign a certificate in the preſence of a magiſtrate, in which the names of the horſe and mare are mentioned, with their pedigrees. When the mare drops her foal, witneſſes are called again, and another certificate is drawn up and ſigned; and theſe vouchers are given with the animal, like the deeds of an eſtate, when it is ſold.

The Arabian horſes are generally of a middling ſize, neat and clean in their ſhape and limbs, and of a thin and ſlender figure. Their keepers curry and feed them morning and evening, and only let them drink two or three times in the day. About March, when the graſs is ſtrong and plentiful, they ſoil them, and devote this ſeaſon likewiſe to procreation; obſerving the cuſtom, which we have probably derived from them, of throwing cold water upon the mare as ſoon as the ſtallion deſcends from her back. When the ſpring is paſt, the horſes are taken from the paſtures, and kept for the reſt of the year without graſs or hay, ſolely upon barley, with a certain portion of ſtraw. When the colts are about eighteen months old, they ſheer the hair of their tails, in order to make it grow thicker and ſtronger. They begin to ride their colts at the age of two years, or two and a half at moſt.

The beſt breeds of this country are ſaid to be ſprung from the wild horſes of the Deſert, of which, many ages ago, a ſtud was compoſed, which increaſed the breed, and furniſhed Europe, Aſia, and Africa with theſe noble animals. The beſt horſes are, therefore, immediately or remotely deſcended from Barbs, deſcended from Arabians, whoſe climate is peculiarly favourable to the breed of horſes.

The Arabian breed is propagated in Barbary, among the Moors, and even among the negroes on the banks of Gambia and Senegal, where they are fed with Indian corn, bruiſed and mixed with milk. Egypt, Turkey, and Perſia are ſupplied with horſes from Arabia. The Barbary horſes are to be found in moſt countries of Europe.

The foreheads of theſe horſes are generally long, ſlender, and ill furniſhed with mane, but riſing diſtinctly and boldly out of their withers; their heads lean and ſmall, and reſembling that of a ſheep; the ears handſome and well placed; the ſhoulders light, ſloping backwards, and flat; their withers fine, and ſtanding high; loins ſhort and ſtraight; flanks and ribs round and full, without having too large a barrel; their haunches ſtrong and elaſtic; the croup often ſomewhat too long; the tail placed high; thighs well turned and rounded; legs clean, well made, and thin of hair; the ſinews detached from the bone, but the paſtern generally too long and bending; the foot good and ſound. Theſe horſes are of all colours; but the moſt common ſort is grey; they are generally cold and ſlow in their paces, and require to be rouzed and animated by the rider, when they will diſcover a great fund of vigour, wind, and ſpeed. They are very light and nimble, formed for running, and are more valued in their offspring than for their own merit, being thought, when tranſported into foreign countries, to get colts which excel their ſires in goodneſs; on which account they are valuable in ſtuds.

The Algerines are ſaid not to like to caſtrate their horſes, but only ſqueeze their teſticles when they are about three months old, and thus render them incapable of propagation.

It is thought that the horſes of the kingdom of Morocco are the beſt, and next to them a breed called the mountain barbs, which are ſure-footed, of a gentle diſpoſition, and very attentive and docile. Their walk is free and bold, and their gallop very rapid.

In Turkey, Arabia, and Perſia, they expoſe the dung of their horſes in the ſun, and when it is capable of being finely powdered, they ſpread it under them inſtead of litter, which gives their coat a beautiful gloſs and luſtre. The Perſian horſes are reckoned next in value to thoſe of the Arabians.

The climate of India is unfriendly to horſes, which are generally very ſmall, and fed in the day-time with a little hay, and at night with peas boiled with ſugar and butter. They ſometimes feed them in the rice-fields, and when fleſh is plentiful, boil the offal to rags, and, mixing it with butter and ſome ſorts of grain, form balls, which they thruſt down the throats of horſes. In a ſcarcity of proviſion, they give them opium. The horſes of the country are naturally very vicious; and the Perſian horſes, being more gentle and tractable, are often valued at a thouſand guineas each, while thoſe of India ſell for fifty or one hundred.

The Tartar horſes are of a moderate ſize; but they are ſtrong, nervous, proud, full of ſpirit, bold, and active. They are of a good ſize for the ſaddle, and are pacers by nature. Their owners, like the ancient Geloni and Sarmatians, make the animals ſupply them with food; for they eat their fleſh at this day, as well as the curds, or "lac concretum" of the mare's milk, mentioned by many ancient writers. The Tartars have been famous in all ages, under different names, for their love of horſes and ſkill in riding. The diſtrict, called Little Tartary, has a breed of ſmall horſes, which the inhabitants value ſo much, as never to permit them to paſs into the hands of ſtrangers.

Circaſſia, Mingrelia, and the adjacent parts, abound with horſes of a better mould, and juſter proportions than thoſe of Tartary, and they are conſequently admired and valued, more eſpecially as they are equal to the greateſt fatigue. Some of the iſlands in the Archipelago are furniſhed with good and valuable horſes, eſpecially Crete; but they are not entitled to any farther notice. The horſes of Ruſſia are not much regarded by other nations. They are ſmall but hardy, and capable of enduring great fatigue. Thoſe of the Turkiſh breed are handſome, and finely ſhaped, but too ſlight and weak for heavy cavalry. The Kalmuck horſes are ſomewhat higher than the Ruſſian common horſes, and ſo tough and ſtrong in their conſtitution, as to be able to run three or four hundred Engliſh miles in three days. They ſubſiſt, ſummer and winter, ſolely upon graſs in the great deſerts, which are between the rivers Don, Volga, and Yaik. They are collected in great herds of four hundred, five hundred, or even a thouſand. They are excellent ſwimmers, and paſs the river Volga, where it is from one to two miles broad, with great eaſe. The Nogay horſes are a hardy breed belonging to the Tartars of that tribe, ſubject to the Kalmuck khan. The Turcomans, a free nation, living between the Caſpian ſea and the lake Aral, have horſes of the ſame nature with thoſe of the Nogay Tartars; and the horſes of the Baſhkirs are ſtouter and better than thoſe of the Nogay tribe. The "ſtep," or wild horſe, is an horſe of the Deſert, of which there are three different kinds, which feed reſpectively together, in herds, or taboons, of thouſands. All kinds of horſes are eaten by the Tartars and Kalmucks; and a foal is reputed a great dainty. Mare's milk is a frequent drink, which, when kept and fermented, becomes inebriating. The Tartars of the Crim never undertake an excurſion without allowing three horſes to one rider. The Poliſh horſes are very hardy, ſtrong, and uſeful, but they are generally of a middling ſize. In the marſhy parts of Pruſſia, and towards the mouth of the Viſtula, there is a breed of good, tall, ſtrong, horſes, reſembling thoſe of Frieſland, but of inferior value.

The horſes of Sweden are low and ſmall, and the Norway breed may be comprehended under the ſame deſcription, but they are nervous, hardy, and active. Denmark, and alſo Holſtein and Oldenburg, boaſt a large variety of horſes, which have ſo much vigour, pride, courage, and grace, that for the coach, the ſervices of war, and the manege, they can be ſurpaſſed by few, though they often fail with reſpect to elegance of limb and ſymmetry of parts; having thick foreheads,

heads, ſhoulders ſomewhat heavy, backs rather long, and croups too narrow to correſpond with the foreparts. In the iſlands of Ferroe there is a race of horſes of ſmall growth, but ſtrong, ſwift, and ſure of foot, paſſing with eaſe and ſafety over high hills. They are never ſhod, and feed abroad without ſhelter both ſummer and winter. In Suderoe, one of theſe iſlands, they have a lighter and ſwifter breed than in any of the reſt; the inhabitants catch their ſheep, which are wild, by hunting them with a dog, and purſue them with their horſes. The horſes of Lapland are ſmall of ſtature, but active and willing; they are uſed only in the winter ſeaſon, in drawing ſledges over the ſnow, and tranſporting wood, forage, and other neceſſaries; but in ſummer they are turned into the foreſts, where they form ſeparate troops, ſtrictly confined to their own quarters.

The Spaniſh horſes are much commended: ſome make them ſecond to the Arabians, and place them before the Barb. Thoſe of the fineſt breeds are generally well truſſed, and well knit horſes, active and ready in their paces, of a quick apprehenſion and retentive memory, wonderfully docile and affectionate to man; full of ſpirit and courage, tempered with mildneſs and good nature, and generally very eaſy in all their paces; for the moſt part of a moderate ſize. Thoſe which are bred in Upper Andaluſia are deemed the moſt valuable. The Portugal horſes, or rather mares, were famous of old for being very fleet and long-winded; but of late it is ſaid they are much degenerated. The Italian horſes were formerly more beautiful, and of greater fame, than the preſent race. Although this country is not now deſtitute of many generous and beautiful breeds, diſperſed in ſtuds, which are formed in different ſtates or diſtricts, the Neapolitan horſes have always been renowned, and ſhine both under the ſaddle and in the traces. Great numbers are bred in Sicily, which has always been extolled for the ſuperior excellence of its horſes. Thoſe of Sardinia and Corſica are ſmall, but nimble, bold, and full of ſpirit. The Swiſs horſes partake of theſe qualities, and were formerly accounted ſerviceable in war. Germany is not deſtitute of generous and noble horſes, uſeful for many purpoſes: but they are reckoned to be heavy and not good-winded. They have, however, finer breeds obtained from Turks and Barbs, which are kept as ſtallions, and alſo from Italians and Spaniards. In the chace and running they are inferior to the Hungarian and Tranſylvanian horſes. The horſes of Bohemia are not diſtinguiſhed by any eminent qualities. The Huſſars and Tranſylvanians are accuſtomed to ſlit the noſtrils of their horſes, under a notion of giving their breath a free paſſage, and improving their wind, as well as to render them incapable of neighing, which in war would be often inconvenient. The Croatian horſes are nearly allied in qualities and character to the Hungarian and Bohemian: theſe, as well as the Poles, are remarkable for being, as the French term it, "Begut," or keeping the mark in their teeth as long as they live.

Holland furniſhes a race of horſes, which are principally ſerviceable in the coach: the beſt come from Frieſland. The Flemiſh horſes are inferior in value to the Dutch, having big heads with a channel towards the noſtrils; their feet are immoderately large and flat, and their legs ſubject to watery humours and ſwellings in the heels. France abounds in horſes of all kinds, but by no means excels. The beſt of thoſe fit for the ſaddle come from Limouſin: they reſemble the Barbs in many particulars, and like them are fitteſt for hunting, but they are not ripe for work till they are eight years old. There are alſo very good "Bidets" or ponies in Auvergne, Poitou, and Burgundy. Next to thoſe of Limouſin, Normandy claims precedence, for its handſome, generous, and uſeful breed. Lower Normandy, and the diſtrict of Cotentin, furniſh a very good ſort for the coach, which are nimbler, and have more elaſticity in their motions than the Dutch horſes. The French horſes are apt to have their ſhoulders too looſe and open, as thoſe of the Barbs are too confined and narrow.

The finer and better ſort of the more modern Engliſh horſes are deſcended from Arabians and Barbs, and frequently reſemble their ſires in looks and appearance, but differ from them conſiderably in ſize and mould, being more furniſhed, ſtout, and luſty. In general they are ſtrong, nimble, of good courage, capable of enduring much fatigue, and both in perſeverance and ſpeed ſurpaſs all horſes in the world. However, it is objected to Engliſh horſes, that they want grace or expreſſion in their figure and carriage; that they are obſtinate and ſullen; that they have ſtiff ſhoulders, and want ſuppleneſs in their limbs, which render them unfit for the manege. England has at all times, even in its rudeſt ſtate, been poſſeſſed of a breed of horſes ſufficient to anſwer every neceſſary purpoſe. But it is probable, that thoſe now uſed in the ſervice of war, as well as for draught, are an offspring of the German or Flemiſh breed, meliorated by our ſoil, and a judicious culture; as our race horſes derive their origin from Arabia. The venerable Bede ſays, that the Engliſh began to uſe ſaddle horſes about the year 631, when prelates and others rode on horſe-back, who till that time were accuſtomed to walk. In the reign of Athelſtan the Engliſh became ſo jealous of their horſes, which were alſo held in high eſteem by foreigners, that a law was made by that monarch to prohibit the exportation of them, unleſs they were deſigned for preſents; and in the reign of this prince many foreign horſes were introduced into this kingdom. The variety of breeds in this iſland was farther augmented by William the Conqueror, and particularly by Roger de Beleſme, earl of Shrewſbury, in his time, who introduced the Spaniſh ſtallions into his eſtate in Powis Land, from which that part of Wales was for many years celebrated for a ſwift and generous race of horſes. (See on this ſubject Berenger's Hiſtory and Art of Horſemanſhip, vol. i. paſſim; Buffon's Nat. Hiſt. by Smellie, vol. iii. p. 306, &c. Pennant's Britiſh Zoology, vol. i. p. 1, &c.) The importation and breed of horſes were much promoted by Edward II. and Edward III. Polydore Virgil informs us, that in the reign of Henry VII. the Engliſh were wont to keep large herds of horſes in their paſtures and common fields; and by 11 Hen. VII. cap. 13. it was prohibited to convey horſes out of the realm without the king's licence, on pain of forfeiture. In the reign of the ſucceeding prince, a particular regard was paid to the raiſing of a breed of good and ſtrong horſes; and accordingly ſeveral laws were made, enjoining thoſe who had parks, incloſures, &c. to keep at leaſt two brood mares, of a certain ſize, &c. and prohibiting ſtoned horſes from being put into foreſts or commons where mares were kept within certain counties, which were above the age of two years, but not fifteen hands high, on pain of forfeiture; and ſcabbed horſes from being kept in ſuch places, on pain of 10*s*. 27 Hen. VIII. cap. 6. 32 Hen. VIII. cap. 13.

By 1 Ed. VI. cap. 12., and 2 & 3 Ed. VI. cap. 33. horſe-ſtealers are excluded from the benefit of clergy. By theſe prudent and judicious meaſures, the Engliſh breed of horſes was not only improved in ſtrength and ſize, but alſo greatly increaſed in number. Till the uſe of coaches (ſee COACH) was introduced in the reign of queen Elizabeth, ſaddle horſes and carts were the only methods of conveyance for all ſorts of people; and the queen rode behind her maſter of the horſe, when ſhe went in ſtate to St. Paul's. By the 2 & 3 Ph. and M. cap. 7. and 31 Eliz. cap. 12. it is enacted, in order to prevent horſes from being ſtolen or ſold in private places, that owners of fairs and markets ſhall appoint toll-takers or book-keepers, who are to enter the names of buyers and ſellers of horſes, &c. And to alter the property, the horſes muſt be rid or ſtand in the open fair one hour; and all the parties to the contract muſt be preſent with the horſe. Sellers of horſes are to procure vouchers of the ſale; and the names of the buyer, ſeller, and voucher, price of the horſe, the colour, and one ſpecial mark at leaſt, are to be entered in the toll-taker's books, and a note of the ſame delivered to the buyer; and if any perſon ſhall ſell a horſe without being known to the book-keeper, or bring in a voucher; or if any one ſhall vouch, without knowing the ſeller, or the book-keeper ſhall make an entry, without knowing either; in each of theſe caſes the ſale is void, and a forfeiture is incurred of 5*l.* The owner may ſeize and take his horſe again, or have an action of detinue, &c. A ſtolen horſe, though ſold according to the direction of the act, may be redeemed and taken by the owner within ſix months, repaying the buyer what he ſhall ſwear he gave for the ſame. Any perſon killing a horſe in the night-time is guilty of felony, and liable to tranſportation for ſeven years; and maiming a horſe incurs the penalty of treble damages. 22 & 23 Car. II. cap. 7.

Horſes in hackney-coaches are to be 14 hands high. (9 Anne, cap. 23.) If hired horſes are abuſed by immoderate riding, &c. there lies an action of treſpaſs on the caſe. The act 26 Geo. III. c. 71. requires every perſon who keeps or uſes any horſe, or place for the purpoſe of ſlaughtering any horſe, &c. or cattle which ſhall not be killed for butcher's meat, to take out a licence at the quarter ſeſſions, and to cauſe his name and the words "Licenſed for ſlaughtering horſes purſuant to an act paſſed in the 26th year of his majeſty king George III." to be painted or fixed over the door of ſuch houſe or place; and an inſpector ſhall be appointed by pariſh officers, whoſe duty is ſpecified by the ſaid act. Slaughtering horſes, &c. without a licence and conformity to the requiſitions of the ſaid act, incurs the guilt and puniſhment of felony.

The duties impoſed by 43 Geo. III. c. 161. and 45 Geo. III. c. 13. on all horſes, mares, and geldings, kept by any perſon for riding, or drawing any carriage, chargeable with the duty on carriages, appear in the following ſchedule.

Number thereof.	Amount of Duty for each Horſe, Mare, or Gelding.		
	£.	*s.*	*d.*
For 1 ſuch horſe, mare, or gelding - -	2	8	0
2 - - - - -	4	0	0
3 - - - - -	4	8	0
4 - - - - -	4	11	0

18 - - - - -	5	6	6
19 - - - - -	5	7	0
20 and upwards - - - -	5	8	0

The ſaid duties are payable annually, ſubject to the following exemptions:

1. Any perſon who ſhall keep any horſe, mare, or gelding, which ſhall be uſed without fraud for the purpoſe of huſbandry, or of drawing any carriages (except ſuch as are liable to any duty by this act), or carrying burdens in the courſe of the trade or occupation of the perſon or perſons to whom ſuch horſe, mare, or gelding ſhall belong, although ſuch horſe, mare, or gelding ſhall be uſed for riding on the occaſions and in manner hereinafter-mentioned; that is to ſay, when returning from any place to which any load or burden ſhall have by ſuch horſe, mare, or gelding, been drawn or carried, or in going to any place from whence any load or burden ſhall be to be brought back by any ſuch horſe, mare, or gelding, or on account of ſuch horſe, mare, or gelding having been uſed for the purpoſe of riding to procure medical aſſiſtance, or for the purpoſe of riding to or from market, or to or from any place of public worſhip, or to or from any election of members to ſerve in parliament, or to or from any courts of juſtice, or to or from any meeting of the commiſſioners of taxes.

2. Any perſon occupying a farm as tenant at rack-rent, the rent of which ſhall be leſs than 70*l.* a year, and making a livelihood ſolely thereby; or any perſon occupying any eſtate on any other tenure than as tenant at rack-rent ſolely, or ſuch eſtate, together with a farm at rack-rent, the whole value of which ſhall be leſs than equivalent to a farm at the rack-rent of 70*l.* a year (reckoning the value of every eſtate occupied by the owner thereof, or on any tenure other than rack-rent, as equivalent to double the amount of the like farm at rack-rent), and making a livelihood ſolely by ſuch his own eſtate, or by ſuch eſtate and farm jointly, and uſing occaſionally for the purpoſe of riding, any horſe, mare, or gelding, which ſhall be *bonâ fide* kept and uſually employed for the purpoſes of huſbandry.

3. Any perſon occupying a farm, and making a livelihood ſolely thereby, or any perſon carrying on a trade, and making a livelihood ſolely thereby; or making a livelihood by ſuch occupation and trade jointly: or any eccleſiaſtical perſon, not poſſeſſed of an annual income of 100*l.* or upwards, whether ariſing from any eccleſiaſtical preferment or otherwiſe, for one horſe, mare, or gelding, uſed only for the purpoſe of drawing any carriage with leſs than four wheels, liable to the duty hereby made payable on taxed carts.

The duties on horſes let to hire are as follow: For every horſe, mare, or gelding, let to hire for the purpoſe of riding, or of drawing any ſuch carriage as aforeſaid, for any period of time leſs than one year, in any manner ſo that the ſtamp-office duty, payable by law on horſes let to hire, ſhall not be payable, the ſum of 2*l.* 8*s.*

To be charged annually on the perſon or perſons letting the ſame; provided, if a due return thereof ſhall not be made by the hirer or hirers, according to this act, the progreſſive duty, as ſet forth in the former ſchedule, ſhall be chargeable in reſpect of every ſuch horſe, mare, or gelding, on the perſon or perſons hiring the ſame, and making ſuch default as aforeſaid.

The duties payable on race-horſes are as follow: For every horſe, mare, or gelding, *bonâ fide* kept for the purpoſe of racing or running for any plate, prize, or ſum of money, or other thing, or kept in training for any of the ſaid purpoſes, whether in the ſtables of the proprietor or proprietors, or of any other perſon or perſons, the ſum of 2*l.* 8*s.*

The ſaid duty to be charged annually on the perſon or perſons having the cuſtody, charge, or management of ſuch horſes, mares, or geldings.

The duties charged on horſes not otherwiſe charged, and on mules, are as follow: For every horſe, mare, or gelding, not chargeable with any duty according to the preceding ſchedule, and for every mule, except in the caſes hereinafter mentioned wherein other duties are made payable, the ſum of 12*s*. 6*d*.

The duties on huſbandry horſes are as here ſtated: Any perſon occupying a farm at rack-rent, the rent of which ſhall be leſs than 20*l*. (in Wales 10*l*. ſterling) a year, and making a livelihood (or in Wales principally) ſolely thereby, or occupying any eſtate on any other tenure at rack-rent ſolely, or ſuch other eſtate, together with a farm at rack-rent, the value of which in the whole ſhall be leſs than equivalent to a farm at the rack-rent of 20*l*. (in Wales 10*l*. ſterling) a year, (reckoning the value of every eſtate occupied by the owner thereof, or on any tenure other than at rack-rent, as equivalent to double the amount of the like farm at rack-rent) and making a livelihood ſolely by ſuch his own eſtate, or by ſuch eſtate and farm jointly or principally thereby, and likewiſe a profit by any trade or employment, and keeping not more than two horſes, mares, geldings, or mules, *bonâ fide* for the purpoſe of ſuch occupation, ſhall be charged for each of ſuch two horſes, mares, geldings, or mules, the ſum of 2*s*. 6*d*.

The exemptions to the ſeveral duties above ſpecified are,

1. Any horſe, mare, or gelding, belonging to his majeſty, or any of the royal family.

2. Any poſt-maſter, inn-keeper, or other perſon duly licenſed by the commiſſioners of ſtamps, in reſpect of any horſe, mare, or gelding, let to hire by him, in any manner where the ſtamp-office duty payable on horſes let to hire ſhall be duly ſatisfied and paid on each letting, and which ſhall not, on any occaſion, be uſed for any other purpoſe.

3. Any perſon duly licenſed to keep any public ſtage coach or carriage for conveying paſſengers for hire from different places in Great Britain, in any reſpect of any horſe, mare, or gelding, which ſhall be actually and ſolely employed for that purpoſe.

4. Any perſon licenſed by the commiſſioners for hackney coaches within London and Weſtminſter, and the ſuburbs thereof, to keep any hackney coaches, for any horſes, mares, or geldings, kept for the purpoſe of drawing ſuch coach, in reſpect of the duties before mentioned, and for two horſes, mares, or geldings, and no more, kept for the purpoſe of drawing each coach ſo licenſed in reſpect to the duties in the former ſchedule.

5. Any dealer in horſes, aſſeſſed to the duties hereby made payable on ſuch dealers, for any horſe, mare, or gelding belonging to ſuch dealer, and kept *bonâ fide* for ſale, and not kept or uſed for any other purpoſe, or in any other manner.

6. Any perſon who, on account of poverty, ſhall be diſcharged from the aſſeſſment made in reſpect of his dwelling houſe, in purſuance of the regulations of this act, for any horſe, mare, or gelding, provided ſuch perſon ſhall not keep more than one ſuch horſe, mare, or gelding, and the ſame ſhall not be let to hire.

7. Any rector, vicar, or curate, actually doing duty in the church or chapel of which he is incumbent, who ſhall not be poſſeſſed of an income of 60*l*. per annum or upwards, whether ariſing from eccleſiaſtical preferment or otherwiſe; and who ſhall not keep more than one horſe, mare, or gelding, for the purpoſe of riding, which otherwiſe would be chargeable with duty according to this act, except ſuch perſon who ſhall occaſionally perform the duty appertaining to any rector, vicar, or curate, without being the regular officiating miniſter of the pariſh or place in which ſuch duty ſhall be performed.

8. Every perſon inrolled, or to be inrolled, and ſerving in any corps of yeomanry or volunteers, which ſhall hereafter be continued or formed, with the approbation of his majeſty, under officers commiſſioned by his majeſty or lieutenants of counties, or others who may be ſpecially authorized by his majeſty for that purpoſe, who ſhall have attended the exerciſe of ſuch corps, five days of muſter and exerciſe at the leaſt in the courſe of the preceding year, and who ſhall be returned in the muſter rolls of the ſaid corps, as required by law, and certified to have ſo attended, unleſs prevented by actual ſickneſs (ſuch ſickneſs to be certified by ſome medical practitioner to the commanding officer of ſuch corps), and who ſhall be returned in the ſaid muſter-roll of ſuch corps, as having uſed any horſe, mare, or gelding, for ſervice during ſuch days of muſter and exerciſe, ſhall be exempted from the payment of the duties ſet forth in the preceding ſchedules in reſpect of ſuch one horſe, mare, or gelding; ſuch exemption to be returned and claimed in the manner in which exemptions are directed to be returned and claimed by this act: but every claim of ſuch laſt mentioned exemption ſhall be proved by the certificate under the hand of the officer commanding the corps in which ſuch perſon ſhall be inrolled, which certificate ſhall, between the 5th April and the 5th May in every year, be delivered to the aſſeſſors of the pariſh where he ſhall reſide; and every perſon claiming to be ſo exempted, ſhall be chargeable thereto, unleſs ſuch certificate ſhall have been delivered purſuant to this act; which certificates made up, returned, and certified, ſhall be deemed ſufficient and valid for the purpoſes aforeſaid; but if from any variation of circumſtances, or other reaſon, the ſaid form cannot be ſtrictly adhered to, inſtruments of a ſimilar import may nevertheleſs be received in proof, at the diſcretion of the commiſſioners executing this act for the diſtrict.

9. Any non-commiſſioned officer or private of any of the regiments of cavalry, or in the artillery, for any horſe uſed in his majeſty's ſervice.

Horſe-dealers are chargeable as below ſtated:

Every perſon who ſhall uſe or exerciſe the trade and buſineſs of a horſe-dealer within the cities of London and Weſtminſter, and the liberties of the ſame reſpectively, the pariſhes of St. Mary-le-bone and St. Pancras, in the county of Middleſex, the weekly bills of mortality, or the borough of Southwark, in the county of Surry, the annual duty of 20*l*.

Every perſon who ſhall uſe or exerciſe the trade and buſineſs of a horſe-dealer in any other part of England, or in Wales, or the town of Berwick-upon-Tweed, the annual duty of 10*l*.

For the duties of poſt-horſes, ſee the article Post.

A horſe is uſually divided into three principal parts, *viz*. the *fore-hand*, the *body* or *carcaſe*, and the *hind-hand*. The *fore-hand* includes the head, neck, withers, breaſt, and fore-legs. The *body* is compoſed of the back, kidnies, ribs, belly and flanks. The *hind-hand* comprehends the rump, haunches, tail, buttocks, ſtiffle, thighs, hocks, and the other parts of the hind legs. By another mode of diviſion, the horſe is diſtinguiſhed into four parts, *viz*. the head, the body, and the fore and hind trains. The *body* is compoſed of the back, the kidnies, the belly, the ribs, and the flanks. The *fore-train* conſiſts of the neck, the ſhoulders, the breaſt, and the fore-legs; and the *hind-train* of the rump, the tail, the haunches, and the hind legs. Theſe ſeveral parts may be more diſtinctly underſtood by means of the ſubjoined detail, and a reference to the *Plate of Horſe*. A, the two bones correſponding to the *temples* of a man, and called by the ſame name: B, the *eye-pits*, or two cavities between the eye and ear, above the eye brows: C, the *vives*; the parotid glands, ſituated between the ear, and the locking of the under jaw: D, the *face* or *chanfrin*; the fore part of the head from the eyes to the noſtrils: E, the *rim of the noſtrils*; the cartilage which forms the circular aperture of the noſtrils, and terminates them above and below: F, *tip of the noſe*; the partition which divides the noſtrils, terminating at the upper lip: G to H, the bones of the lower jaw: H, the *chin*: I, the beard.

Gatherers. The two fore teeth.

Middle teeth. Thoſe adjoining to the gatherers.

Corner teeth. The laſt on each ſide.

Tuſhes. The two canine teeth on each ſide, and in each jaw.

Bars. The ſpaces between the cutting teeth and grinders, filled with ridges, which run acroſs the palate.

K, the *neck*, which is bounded above by the mane, and below by the throat, extending from the ſhoulders to the head: L, the *tuſt* or *toupet*; that part of the mane which lies between the two ears, and hangs down on the front: M, the *withers*; the place where the two ſhoulders approach each other between the neck and back: N, the *ſhoulders*, extending from the withers M, to the top of the *fore hand*, or fore-leg O: P, the *cheſt* or breaſt: Q, the *back*, reaching from the withers M, to the reins S: R, the *navel*; the part between the back and reins; a very abſurd term, as the *navel* is in the lower part of the belly: S, the *reins*; this term is often uſed, though improperly, to expreſs the whole ſpine of the horſe: T, the *ſides*, which are formed and limited by the ribs: V, the *coffer*; the hollow formed by the contour of the ribs. The name *belly* is given to the part extending from V to the flank: X, the *flanks*; the extremity of the belly, at the termination of the ribs, below the kidnies, and reaching to the haunch-bones: Y, the *haunch*, formed, as in man, by the haunch-bone: Z, the *crupper*, which is round, and reaches from the kidnies to the tail. The *tail* is diſtinguiſhed by two parts, the *hair* and the [illegible]: *a*, the *buttocks*, are ſituated below the crupper and the origin of the tail, and extend to the place when [illegible] hind-leg joins the body: *b*, the *ſhoulder-blade*: *c*, the [illegible]; both of theſe are included by horſemen under the [illegible] *er*: *d*, the *elbow*: *e*, the *arm*: *f*, the *knee*, or joint ſituated below the arm, a term improperly applied to a horſe, as it correſponds to the wriſt in man: *g*, the *ſhank* or *canon*; the ſecond part of the fore-leg. It begins at the articulation of the knee, terminates at the fetlock joint *i*, and anſwers to the metacarpus in man: *h*, the *tendon*, commonly called the backſinew: *i*, the *fetlock* joint: *k*, the *tuft* of hair which ſurrounds a kind of ſoft horn ſituated behind the ſhank: *l*, the *paſterns*; the part of the leg which extends from the fetlock-joint to the hoof: *m*, the *coronet*; the place where the hoof joins the leg, and is decorated with long hair falling down all around the hoof: *n*, the *hoof* repreſents the nail in man; the fore-part of it, *u*, is called the *toe*, and the ſides, *o*, the *quarters*. The hind-part of the hoof is a little raiſed, and divided into two parts, both included under the name *heel*; they extend to the middle of the under part of the foot, and uniting again under the ſole, or bottom of the foot, form the *frog*: *p*, the *ſtiffle*, is properly the articulation of the knee, and contains the knee-pan: *q*, the *thigh*; it extends from the ſtiffle and extremity of the buttocks to the ham *r*, and anſwers to the leg in man. Accordingly, the horſe's thigh has a fleſhy part *s*, reſembling the calf of a human leg: *t*, the *hock* or *ham*, is the joint at the extremity of the thigh, and bends forwards. This articulation correſponds with the *tarſus* in man. The hinder-part of the joint, called the hock, is properly the *heel*. What is commonly called the *great ſinew*, which ariſes from the point of the hock, and terminates in the foot, is a tendon, anſwering to the *tendo Achillis* inſerted into the human heel: *u*, the *ſhank*: *x*, the *paſtern joint*: *y*, the *paſterns*: *z*, the *foot*, as in the fore-leg. (Buffon's Nat. Hiſt. by Smellie, vol. iii.) Of moſt of theſe parts a further account will be found under the reſpective articles.

The maſters of this art lay it down, that a horſe, to be good and well-made, muſt have three parts like thoſe of a woman; *viz.* the breaſt, which is to be broad, the hips round, and the mane long; three of a lion, *viz.* countenance, intrepidity, and fire; three of a bullock, *viz.* the eye, noſtril, and joint; three of a ſheep, *viz.* the noſe, gentleneſs, and patience; three of a mule, ſtrength, conſtancy, and foot; three of a deer, head, leg, and hair ſhort; three of a wolf, throat, neck, and hearing; three of a fox, ear, tail, and trot; three of a ſerpent, memory, ſight, and turning; three of a hare or cat, running, walking, and ſuppleneſs.

Of all quadrupeds, ſays M. Buffon, the horſe poſſeſſes, along with grandeur of ſtature, the greateſt elegance and proportion of parts. By comparing him with the animals immediately above or below him, we find that the aſs is ill made; that the head of the lion is too large; that the limbs of the ox are too ſlender and too ſhort, in proportion to the ſize of his body; that the camel is deformed; and that the groſſer animals, as the rhinoceros and elephant, may be conſidered as rude and ſhapeleſs maſſes. The great difference between the head of man and that of the quadrupeds, conſiſts in the length of their jaws, which is the moſt ignoble of all characters. But, though the jaws of the horſe be very long, he has not, like the aſs, an air of imbecility, nor, like the ox, of ſtupidity. The regularity and proportion of the parts of his head give him a light and ſprightly aſpect, which is well ſupported by the beauty of his cheſt. He elevates his head, as if anxious to exalt himſelf above the condition of quadrupeds. In this noble attitude, he regards man face to face. His eyes are open and lively, his ears handſome and of a proper height, being neither too long, like thoſe of the aſs, nor too ſhort, like thoſe of the bull. His mane adorns his neck, and gives him the appearance of ſtrength and of courage. His long buſhy tail covers and terminates with advantage the extremity of his body. His tail, very different from the ſhort tails of the deer, elephant, &c. and from the naked tails of the aſs, camel, rhinoceros, &c. is formed of long thick hairs which ſeem to ariſe from his crupper, becauſe the trunk from which they proceed is very ſhort. He cannot, like the lion, elevate his tail, but, though pendulous, it becomes him better: and, as he can move it from ſide to ſide, it ſerves him to drive off the flies which incommode him; for, though his ſkin be very firm, and well garniſhed with cloſe hair, it is extremely ſenſible.

The attitude of the head and neck contributes more than all the other parts of his body, to give him a graceful aſpect. The ſuperior part of the neck from which the mane iſſues, ſhould firſt riſe in a ſtraight line from the withers, and then, as it approaches the head, form a curve nearly ſimilar to that of a ſwan's neck. The inferior part of the neck ſhould have no curvature, but riſe in a ſtraight line from the poitrel, or breaſt, to the under jaw, with a ſmall inclination forward. If it roſe in a perpendicular direction, its ſymmetry and gracefulneſs would be diminiſhed. The ſuperior part of the neck ſhould be thin, with little fleſh near the mane, which ought to be garniſhed with long delicate hair. A fine neck ſhould be long and elevated, but proportioned to the general ſize of the animal. When too long, the horſe commonly throws back his head; and, when too ſhort and fleſhy, the head is heavy to the hand. The moſt advantageous poſition of the head is, when the front is perpendicular to the horizon.

The head of a horſe ſhould be thin and meagre, and not too long. The ears ſhould be ſmall, erect, but not too ſtiff, narrow, and placed on the upper part of the head, at a proper diſtance from each other. The front ſhould be narrow and a little convex, the eye-pits, or hollows between the eyes and ears, well filled, and the eye-lids thin; the eyes ſhould be pretty large and prominent, clear, lively, and full of fire; the pupil ſhould be rather large, the under jaw a little thick, but not fleſhy, the noſe ſomewhat arched, the noſtrils open and deep, and divided by a thin ſeptum or partition. The mouth ſhould be delicate and moderately ſplit, lips thin, withers ſharp and elevated, the ſhoulders flat, and not confined; the back equal, a little arched lengthwiſe, and raiſed on each ſide of the back-bone, which ought to have the appearance of being ſunk; the flanks ſhould be ſhort and full, the crupper round and plump, the haunches well furniſhed with muſcular fleſh, the dock or fleſhy part of the tail firm and thick, the thighs large and fleſhy, the hock round before, broad on the ſides, and tendinous behind; the ſhank thin before, and broad on the ſides; the tendon (or tendo Achillis) prominent, ſtrong, and well detached from the leg-bone, and the fetlock ſomewhat prominent, and garniſhed with a ſmall tuft of long hair behind; the paſterns ſhould be of a middling length, and pretty large; the coronet a little elevated, the hoof black, ſolid, and ſhining, the inſtep high, the quarters round, the heels broad, and a little prominent, the frog thin and ſmall, and the ſole thick and concave. We ſhould here add, that few horſes poſſeſs all theſe perfections.

The three natural and ordinary movements of horſes are walking, trotting, and galloping. In walking, the horſe raiſes his feet very little above the ſurface; in trotting, he elevates them a little more; and in galloping, ſtill higher. The walk ought to be ſmart, light, and ſure; the trot ſhould be firm, quick, and equally ſupported; and the fore legs puſhed with rapidity by the hind ones. The trotting-horſe ſhould carry his head pretty high, and keep his body ſtraight; for if the haunches riſe and fall alternately, at every movement, and if the crupper rocks, the animal is too weak for this motion. Beſides the three movements of walking, trotting, and galloping, ſome horſes have another natural motion, which is known by the name of "ambling" or "pacing;" this motion, though leſs quick than the hard trot or gallop, appears, at firſt ſight, to be extremely fatiguing to the animal. The trot is, perhaps, the moſt natural motion of a horſe; but the pace, and even the gallop, are moſt eaſy to the rider.

Horſes are diſtinguiſhed into divers kinds, and are differently denominated, with regard to their ſtrain or country. As the Neapolitan, known by his hawk noſe; the Spaniſh genet, by his ſmall limbs; the Barb, by his fine head and deep hoof; the Dutch, by the roughneſs of his legs; the Engliſh, by a ſtrong knitting together, &c. the Flandrin, &c.

Horſes are alſo diſtinguiſhed, with regard to the uſes or offices they are reſerved for; as the coach-horſe, war-horſe, hunting-horſe, running-horſe, pack-horſe, &c.

Horſes are alſo diſtinguiſhed with regard to their colours; as a *bay*, which admits of divers ſhades or caſts; *viz.* a black-bay, brown-bay, dapple-bay; all which have conſtantly black manes and tails. *Dun* and *mouſe-dun*, having frequently a black liſt along the back, which denominates them *flea-backed.* *Flea-bitten*, which is white ſpotted with red. *Grey*, dapple-grey, ſilver-grey, ſad or powdered grey, black-grey, branded-grey, ſandy-grey, and iron-grey. *Griſſel*, or *rount*, a light fleſh-colour, intermixed with white. *Peach-colour*, or *bloſſom-colour*. *Pyebald*, which conſiſts of two colours, one of them white. *Roan*, a bay, black, or ſorrel, intermixed with white hairs. *Rubican*, black or ſorrel, with a few white hairs ſcattered about his body. *Sorrel*, common ſorrel, red or cow-coloured ſorrel; bright, or light-coloured ſorrel; burnt-ſorrel, all chiefly diſtinguiſhed by the colour of their mane. *Starling-colour*, reſembling a browniſh or blackiſh-grey, only more freckled, or intermixed with white. *Tyger-colour*, much the ſame with the branded-grey, only the ſpots ſmaller. *Wolf-colour*, *deer-colour*, *black*, *white*, &c.

Theſe colours are generally conſidered as ſymbolical of the nature, qualities, &c. of the beaſts, and accordingly their value is much influenced hereby. The dapple-grey is prized for beauty; the brown-bay for ſervice; the black, with ſilver hair, for courage; the roan for countenance; the ſorrel, black without white, and iron-grey, are reputed hot and fiery; the bright-grey, flea-bitten, and black with white ſpots, are ſanguine; the white, dun, and pye-bald phlegmatic and heavy; the mouſe-dun, red-bay, and blue-grey are dull; the peach-colour rarely prove obedient to the ſpur; the ſorrel ſeldom fail of being good, eſpecially if their legs, tails, and manes be black; and the ſame may be ſaid of the flea-bitten, at leaſt thoſe ſo marked in the fore-parts, or over the whole body; or, when only behind, it is an ill ſign.

Indeed, it is hard to lay down any univerſal rules in this caſe. The white, which promiſe the leaſt, often prove good, when black about the eyes and noſtrils; and there are excellent iron-greys, though that is not reputed a good colour. The white colour was anciently the moſt admired, and conſidered as a mark of pre-eminence and ſovereignty. Herodotus reports, that the Cilicians paid an annual tribute of three hundred and ſixty white horſes to Darius, king of Perſia; and in Xerxes' march againſt Greece, the chariot of Jupiter was drawn by eight white Nyſæan horſes, the colour being appropriated religiouſly to the deity. We read likewiſe, in the book of Kings, that the kings of Judah were uſed to dedicate horſes to the ſun. Tacitus ſays, the ancient Germans had certain horſes, which were white, that were conſecrated to their gods. We learn alſo from Livy and Diodorus Siculus, that white horſes were held in high eſtimation in Sicily and at Rome. This was alſo the caſe at Naples; and alſo anciently in our own country. Nevertheleſs, if we may believe Virgil and others, who pretended to prognoſticate the innate properties of horſes by the colour of their ſkins, and other marks, the white ſhould be always rejected, as having few qualities which can render them pleaſing or ſerviceable. Virgil evidently means, not white milk-horſes, but thoſe of a faint pale colour, ſomewhat bordering upon the cream-colour, or whitiſh dun; for he elſewhere commends the whiteneſs of the coats of Turnus's horſes. Claudian, alſo Plautus, Horace, Statius, and Palladius join in celebrating it; and we may reaſonably ſuppoſe that they ſpoke according to the fancy and opinion of the times in which they wrote.

The common marks of a dull, ſtupid horſe, are white ſpots round the eye, and on the tip of the noſe, upon any general colour whatever. Though the vulgar take theſe ſpots for ſigns of ſtupidity, yet it is certain they are marks of the goodneſs of a horſe; and ſuch horſes as have them are very ſenſible and quick upon the ſpur. The French call theſe ſpots *marques de ladre.*

Our dealers in horſes uſe the term mettled horſe to expreſs a creature of that ſpecies which has a great deal of vigour and heart, as they call it. Otherwiſe, there is a great difference between a mettled horſe, a horſe of vigour, and a fiery horſe; but as this is not ſufficiently attended to by gentlemen in their purchaſes of this animal, ſome general rules for the diſtinguiſhing real vigour in a horſe, may be acceptable in a work of this general kind.

When a horſe is ſtanding ſtill, the rider who has a mind to try whether he has vigour in him, ſhould keep him faſt with the bridle-hand, and apply the ſpurs to the hair of his ſides; this is called by horſemen pinching. If the horſe is impatient under this, gathering himſelf up, and endeavouring to go forwards, and champs upon the bit, without thruſting out his noſe, it is a ſign of vigour and right mettle in him. Some caution is to be uſed, however, in judging by this, to diſtinguiſh between a horſe that has vigour really in him, and one that has only a fine ſkin, and is rather tickliſh than mettled. This is the caſe with a great many horſes, and is found by their being very ſenſible of the touch of the ſpur, and ſhewing the appearance of a great deal of mettle and vigour when touched, but immediately loſing the apprehenſion of it. Theſe are of a dull diſpoſition, but only have a tender ſkin.

Pliny tells us, that if a horſe, in drinking, plunged his noſe deep into the water, it was reckoned a ſign of ſpirit and courage; and this notion prevails even at preſent in this country.

The mettled horſe is to be highly valued, but the fiery one is good for nothing; a horſe that is truly vigorous ſhould be calm and cool; he ſhould in general move on patiently, and only ſhew his mettle when it is required of him. The ſureſt method is to chooſe ſuch horſes as are extremely apprehenſive of ſtrokes, and are afraid at the leaſt appearance of their coming. Theſe, at the only cloſing of the legs and thighs, ſeem to be ſeized with fear, and alarmed, but without fretting or fierceneſs. A horſe that walks deliberately and ſecurely, and that without requiring the whip too often, will go on briſkly and without fretting, will go from the walk to the gallop, and as eaſily from the gallop to the walk again, and continually champs upon the bit, and trots with glibneſs, upon the ſhoulder eaſily, and ſnorting a little through his noſtrils; this is generally a creature of true metal and vigour, though it does not riſe to ſuch a fierceneſs as is troubleſome or dangerous. If to theſe good qualities a horſe be well upon his haunches, and have a light and eaſy ſtop, his head well placed and firm, and the feeling of his bit equal and juſt, the gentleman who loves riding will ſeldom need to complain of the price. All the good qualities of a horſe ſhould, however, never recommend him, unleſs he has a good mouth, and a ſenſible obedience to the ſpur.

HORSES, *For the Age, Height, Teeth, &c. of*, ſee AGE, HEIGHT, &c.

HORSE, in *Agriculture*, the general name of a well known animal employed in various ſorts of team labour. There are two principal breeds of horſes in this country; the *race* or *blood* kind, and the *cart*, *plough*, or *team* ſort. It is the latter deſcription that is chiefly uſeful in the buſineſs of cultivating the ſoil. The moſt beneficial varieties of theſe kinds, in this view, would ſeem to be the improved black cart-horſe; the Suffolk punch-horſe, the Cleveland bay-horſe, and the Clydeſdale horſe. The firſt, or black cart-horſe, is the common ſort, met with in particular parts of the counties of Lincoln and York, becoming pretty general in thoſe of Leiceſter, Stafford, Derby, and Warwick; being, in point of ſize, larger than any others in the kingdom; but by nature inactive and ſlow in their movements; beſides being clumſy, and not unfrequently badly proportioned. They are in general more adapted to heavy draughts upon paved roads or ſtreets, than for the purpoſes of ploughing and harrowing the ground, or any other deſcription of farm-labour. The largeſt horſes of this kind are moſtly made uſe of in the drawing of drays, and other ſorts of heavy work, in large towns. The ſize below this is that which is commonly employed in the buſineſs of the field, as well as occaſionally in carriages. The ſmalleſt deſcription of them are uſually bought up for being trained to military uſes. It has been juſtly noticed that the large black dray-horſes, in point of ſize and fatneſs, do not admit of any equal; while in relation to hardineſs, vivacity, and nervous energy, they rank probably amongſt the loweſt of their kind.

The Suffolk punch, or ſecond variety of team-horſe, when of the genuine deſcription, is but a ſhort, plain-looking horſe, though very compact, and more active and hardy than any of the others that are met with in the ſouthern parts of the kingdom. It is a ſort that has, however, lately been much improved. When compared with the above breed, and that of the Cleveland, theſe horſes are of but ſmall ſizes, rarely exceeding fifteen or ſixteen and a half hands in height; they are, however, ſo active, that the cultivators in that diſtrict, as well as in Norfolk, very generally plough two acres a day in the buſy ſeaſons with a pair of theſe horſes, without any driver. This ſort of horſe is very commonly employed in the buſineſs of farming in the ſouthern diſtricts of the iſland. They require to be well kept in regard to food, but amply repay the expence under proper management, by the value of their labour.

The Cleveland bay-horſe, or third variety, is generally clean and well made in moſt of the parts; being very ſtrong and active, anſwering perfectly both for the team, coach, and ſaddle. There are few horſes capable of greater, or longer continued exertion in any of theſe intentions, than theſe. It is uſual for great numbers of theſe horſes to be ſold in the various fairs and markets of the diſtrict in which they are met with, ſuch as are the ſtrongeſt and moſt perfectly formed for the purpoſe of carriage-horſes, thoſe which are lighter in the bone, for the purpoſe of riding, and the others for their uſe in the different operations of huſbandry, &c.

The fourth, or Clydeſdale horſe, is a ſtrong, active, ſteady animal, generally from fifteen to ſixteen hands and a half in height; and probably, for the purpoſes of the cart and the plough, inferior to few in this country. It is ſuppoſed that we are indebted to the accidental circumſtance of ſome of the dukes of Hamilton for this variety, who brought from Flanders ſix coach ſtallions, ſome time about the cloſe of the ſeventeenth century; which, by being croſſed with the beſt mares of the kind found in the Lanark diſtrict, this ſort of horſe was produced. The farmers in the ſouth and ſouth-eaſtern parts of Scotland, are now even principally ſupplied with their team horſes from this and the neighbouring diſtricts. Some are ſold for their uſe as coach and ſaddle-horſes, and taken into the ſouthern parts of the kingdom, as well as for team-labour.

It is ſtated by a late writer, that this horſe "is lighter in the body than the Suffolk punch, and more elegantly formed in all reſpects. His limbs are clean and ſinewy, his neck longer, his head of a finer form, and his eye more ſprightly and animated than in either of the two former kinds. His tread is firm though tending towards the nimble; and he is capable of exerting a wonderful degree of muſcular ſtrength for a ſhort puſh without being hurt by it, which makes him particularly valuable for that hilly country, where there is a neceſſity for calling forth ſuch exertions on innumerable occaſions.

caſions. He is hardy, can live upon any food, and is, perhaps, the thriftieſt horſe for the cart or the plough that is to be found in the iſland, perhaps on the globe itſelf. For theſe purpoſes he is peculiarly adapted by the evenneſs of his temper and the ſteadineſs of his movements. For the plough he is, perhaps, every thing that could be wiſhed; being, in point of ſize, neither ſo large nor ſo unwieldy as to render him a burden to the ſoil; two of theſe horſes in the ſofteſt ſoil, under good management, being perfectly able to draw a full furrow with eaſe; and for horſe-hoeing, or ploughing a light ſoil in good order, one of the lighteſt ſort performs the work with alacrity and eaſe. What a benefit, ſays the writer, would reſult to the nation, were a ſet of judicious experiments to be conducted for a ſufficient length of time, for the purpoſe of aſcertaining the comparative powers and expence of keep of theſe laſt three different varieties of horſes, ſo that any one might know who choſe it, with certainty, the profit or the loſs that would reſult to him from employing the one or the other, for any particular purpoſe that he had in view."

Beſides theſe different varieties of farm-horſes, there are ſeveral horſes of a ſtill ſmaller deſcription, uſually known under the denominations of Galloways, poneys, &c. which may be occaſionally found uſeful in the buſineſs of huſbandry, though moſtly too ſmall in ſize for the forming of plough teams.

Whatever the variety of the breed of a horſe may be, in order to be well formed, it ſhould have the following ſhapes of the different parts: the head as ſmall as the proportion of the animal will admit; the noſtrils expanded, with a fine muzzle; the eyes chearful and prominent; the ears ſmall, upright, and placed near together; the neck, riſing out from between the ſhoulders, with an eaſy tapering curve, ſhould join gracefully to the head; the ſhoulders, being well thrown back, ſhould alſo fall into the neck, at what is termed the points, without being perceived, which probably facilitates the going much more than the narrow ſhoulder; the arm or fore-thigh ſhould be muſcular, tapering from the ſhoulder ſo as to meet a fine ſtraight ſinewy and bony leg; the hoof circular and wide at the heel; the cheſt deep and full at the girth; the loin or fillets broad and ſtraight, and the body round; the hips or hooks by no means wide, but the quarters long, and the tail ſet on ſo as to be nearly in the ſame right line as the back; the thighs ſtrong and muſcular; the legs clean and fine-boned; the bones of them not round but flat, or what is frequently termed lathy. But for the team of the farmer, the principal points to be attended to ſhould be thoſe of not having the neck either too long or too thick; the legs rather ſhort and flat than round and clumſy; the fore-feet even, but not too diſtant; the cheſt wide; the ſhoulders ſtrong but not high; good length of waiſt ſupported by a wide loin; the quarters full and ſomewhat raiſed; the legs ſtrong, firm, and muſcular, and the ſize from 15 to 16 hands in height.

It has been noticed, that horſes being ſomewhat forelow affords them an advantage in the draught, and that a tolerable length of waiſt gives them ſpeed in the walk, which is not unfrequently a point of importance in farm work. Some ſuppoſe that horſes for the purpoſe of farming ſhould be ſimilar to thoſe uſed in riding, only of larger ſizes; and in place of being capable of walking merely two or three miles in the hour, to be able to travel at the rate of four or five; as by that means the farmer would be enabled to plough more land in a given time; and to uſe more diſpatch in the work of the cart or waggon when neceſſary. The utility of a ſtrong active horſe at harveſt time is well known to every one; and in the buſineſs of conveying manure to the field and market work, ſuch properties are not leſs valuable.

By taking care in breeding to have the heads of horſes light, handſome, and well ſet on, and by proper attention in croſſing ſtallions and mares, coach and cavalry horſes of high value may be produced, which, if for ſale by the farmer, would, without doubt, pay him well for his trouble and expence. The breeding of good horſes is not more expenſive than that of bad ones, except in the attention which is neceſſary, though the difference in the price at the market is very great. And it is known to every one, that cart-colts become ready for ſale at an early period. There can be no doubt but that coach-horſes may be bred from mares of the Suffolk kind when covered by horſes of the ſtrong race or hunter ſorts, or the contrary. And ſhould it be the wiſh to rear horſes for ſale as hackneys, it will probably be the beſt method to ſelect both the mare and horſe of the blood ſort, or at leaſt with each ſome blood, which is perhaps better than making uſe of full blood horſes. Theſe ſhould be bred with well ſet on light heads, even and good feet, cloſe before and wide behind; plenty of bone below the knee, and high deep and ſlanting ſhoulders; deep in the girth, handſomely rounded in the barrel, as well as on the hip-bones; ſtraight in the back, but the waiſt long enough to give ſpeed, with the loins and fillets proportionately ſtrong; the tail even with the back-bone. But inſtead of breeding, ſuch farmers as intend to derive a profit from this deſcription of ſtock, may conſtantly find both colts and fillies for his purpoſe in the different fairs, markets, and other places.

Mares, for the purpoſe of breeding, ſhould always be well ſhaped in their different parts; have a gentle and eaſy diſpoſition; be poſſeſſed of a large carcaſe in proportion to their heights; being pretty full in their bellies, and appearing likely to form good nurſes and have plenty of milk. Thoſe intended for ſupplying the teams of the farmer with draught horſes ſhould, according to ſome, be large limbed, cloſe jointed, ſhort necked, wide cheſted, home ribbed with a capacious body; the eyes ſhould be perfectly clear, full, and pellucid, and the noſtrils large and open; the diſpoſition ought to be gentle and tractable, the conſtitution healthy and vigorous, free from blemiſhes of any kind.

The horſe, in this caſe, ſhould be bold and ſpirited, well made, and of a kindly diſpoſition; the conſtitution ſtrong and healthy, the temper good, and wholly free from any ſort of vice and contamination; as upon the good properties and healthy condition of the parents, in a great meaſure depend the future utility and advantage of their offspring. Since general experience has fully ſhewn that in what relates to form and other good qualities in the progeny, more depends on the mare than the horſe; the uſual practice of regarding the horſe more than the mare is highly improper, as being diſadvantageous. The form and other properties of the horſe ſhould always have as much ſimilarity as poſſible to thoſe of the mare, as in this way their joint properties may be more reaſonably expected in the young which they produce, than by violent unnatural croſſing. Where a half-bred mare, for inſtance, is put to a large heavy awkward cart horſe, or the contrary, the offspring muſt naturally turn out an indifferent mongrel breed that has rarely the ſize and ſtrength of the one, or the ſpirit, activity, and fine bone of the other. See BREEDING, LIVE-STOCK, and TEAM.

In breeding the dray-horſe, leſs movement or activity is requiſite, but more power; and the ſame principles are applicable in ſome meaſure to thoſe for the waggon, though in a far inferior degree. For theſe uſes it is important that they be very broad-breaſted, and thick in the ſhoulders, without their lying ſo much backward, or riſing ſo much in the fore-hand, as is the caſe in ſaddle-horſes.

Mares in general are not ſuffered to take the horſe in this country until they are from two and a half to three or four years of age, but continue to breed till they reach a good age, as 12 years and upwards.

The horſe may be permitted to cover from the age of three or four years until he becomes unfit for the purpoſe by age. Stallions ſhould conſtantly be kept high with the beſt ſorts of food, and be well dreſſed and taken care of, as without this attention they never anſwer well.

The ſeaſon at which the mare commonly takes the horſe is moſtly from about the beginning of April until the end of June, the laſt month being generally ſuppoſed the beſt period. An early foal is, however, conſtantly to be preferred to ſuch as are late.

The mare goes with foal uſually about eleven months, but ſometimes exceeds it a few days. It is commonly the main object with farmers, where poſſible, to have their mares covered at ſuch times, as that there may be plenty of graſs at the period of foaling, as well as warm favourable weather, as both are highly beneficial to the new dropped foal.

Mares are in ſome places wholly taken from work ſome weeks before the time of foaling; but this is by no means the general practice of the country. In the eaſtern and midland counties that adjoin them, in which the breeding and rearing of horſes are more perfectly underſtood than in moſt other parts of the kingdom, it is not unfrequently the cuſtom to work them to the very period of foaling. But there are certainly much care and attention neceſſary in working mares that are ſo heavy with foal; as an over heat, too hard labour, a fright, or ſudden jerk, or any other ſimilar cauſe, may endanger not only the loſs of the foal, but alſo that of the mother.

It is the cuſtom in moſt of the improved diſtricts of the kingdom where the breeding and rearing of horſes are practiſed, after foaling to turn the mare and her foal out into a paſture field, where they remain for two or three weeks before the mare is again put to work either in the plough or cart, the foal during the time being ſuffered to ſuckle at pleaſure. After having had this reſt, ſhe is again ſuffered to work in the uſual way, the foal being confined in ſome proper place during the time. In the intention of avoiding the evils ariſing to the foals from bad or over-heated milk, ſome of the Yorkſhire breeders are extremely careful not to ſuffer the mares to go near their foals, after their return from work, until their udders have been well bathed with cold water, and the greateſt part of the milk drawn from them. There is likewiſe another practice which has, perhaps, a ſuperiority to the above, in the ſame diſtrict as well as ſome others; which is, as ſoon as the foal has acquired ſtrength ſufficient, and is fully capable of following its mother, to permit it to accompany her to the field during the time of working, and to ſuckle there as there may be occaſion. In this way the foal has full exerciſe, without incurring any danger from the over-heated milk, it being drawn off ſo frequently. Theſe are the common modes in uſe while the foal is ſuffered to ſuck, which is moſtly about ſix months, as from the time of foaling to Michaelmas, the period at which they are uſually weaned.

In the buſineſs of weaning foals it is a good practice to confine them at a diſtance from their mothers in ſome ſmall ſtable or ſhed for the purpoſe, where there is a rack and manger, in which they may be fed with clean ſhaken hay, and well ſifted oats, bruiſed in a mill. Under this treatment they ſpeedily forget their mothers, and become quite tractable and reconciled to the keeper. They ſhould be permitted to exerciſe and enjoy themſelves in a paſture field or paddock, contiguous to the place of confinement, during the ſunny parts of the middle of the day, it being dangerous to keep them out during the night, on account of their tenderneſs.

When the foals have been weaned, the uſual cuſtom is to put them directly into ſome good freſh paſture, where they may continue ſo long as the weather proves mild and temperate, when, on the approach of winter, they are to be fed with a ſufficient quantity of hay, placed in the ſhed or hovel in the field for the purpoſe, into which they can freely enter at pleaſure. The year following, in the ſummer, they are removed into other paſtures, often the moſt inferior on the farm, where they continue until the commencement of the enſuing winter; when they are either permitted to range in the common paſture fields, or brought home to the yards. It is adviſed by ſome to have the foals fed during the winter ſeaſon with a little corn twice in the courſe of the day; or carrots, with hay, oat-ſtraw, &c, letting them have a well littered ſhed or yard that is perfectly ſheltered. Such colts as are fed at home with green meat cut freſh for them daily during the ſummer ſeaſon, ſhould have a range daily upon a field or adjoining common, for the purpoſe of exerciſe. And the yearling colts ſhould be kept quite ſeparate from the mares with their foals.

In the management of young horſes, thoſe of the cart colt kind are often begun with at about two years of age; and one great object in this buſineſs is firſt to teach them docility, by frequent leading in the halter, as well as to back and go in the ſhafts or traces. But this is better delayed in ſaddle colts till the third year, or the autumn preceding it; and they ſhould now be carefully attended to, and have a good mouth given them, though ſome think but little of it. They ſhould likewiſe be taught to canter handſomely; and when they are of proper ſize, they may be gently wrought in the plough or other ſort of team labour. Their going well, and being quiet in harneſs, render them of more value as well as utility in the opinion of many.

The field work ſuch horſes are at firſt inured to, is generally that of harrowing, to which they ſhould ſeldom be kept more than one-half of the day, when they commence it, and afterwards only very gently, for the remainder of the ſeaſon.

It is the uſual practice of the northern horſe-breeding farmers to diſpoſe of their young ſtock, at two or three years old, to thoſe in the more ſouthern parts of the kingdom, who, after keeping and working them about the ſame length of time, diſpoſe of them to the dealers in the metropolis and other large places. This cuſtom is very common, and extremely convenient to all the different parties engaged in it; as the breeder meets a ready and conſtant market for his young horſes at the times when he wants to be quit of them, and is thereby enabled to carry on the breeding ſyſtem without the danger of being overſtocked. And thoſe who are the firſt purchaſers are able to diſpoſe of them to the dealers in the large cities and other places in the ſouth, as proper opportunities may be afforded, as they are fully aware that a ſupply of young horſes will reach them in proper time to anſwer their intentions. Beſides, the dealers in the metropolis can, without the expence and trouble of travelling into the more northern diſtricts, where the largeſt proportion of young horſes is bred and reared, ſupply themſelves with ſuch as are proper for their uſes in the different counties in their own vicinity. In the carrying on of this buſineſs, beſides the principals, there are generally two agents or more who derive their living from it, the jobber or middle-man, who procures the horſes from the breeders and ſells them to the farmers in the ſouth; and the dealer in the vicinity of the metropolis, who makes the purchaſes from the farmers in the ſouth, at his own riſk, ſtanding the chance of ſale to the buyers in the above place; or who provides them on commiſſion for ſuch dealers. The young horſes are moſtly ſold with their full tails to the dealers; who afterwards make them up by art, ſo as to ſuit their different views. They uſually undergo the proceſſes of docking and nicking, and often various other operations performed upon them. After being kept, or what is often termed made up, by having bran maſhes, or thoſe of coarſe ground oats, and boiled grain, given them for two or three months, they are diſpoſed of by the dealers to their cuſtomers in the metropolis.

The uſual periods of cutting or gelding colts, is either while they are quite young, or when they have attained the age of two years. This is particularly the caſe when it is the intention to keep them, without making uſe of them in labour until the enſuing ſpring. The moſt proper ſeaſon for performing this operation is in the early ſpring months, before the weather begins to get too warm. See CASTRATING and GELDING.

For farming purpoſes it becomes the buſineſs of the cultivator to ſuit the horſes in their ſtrength and ſize, to the nature of the work that is to be done, as where they are diſproportioned in either of theſe reſpects, or in their number, the profits of the farmer muſt be leſſened. And where the ſtable economy is not ſo correct or proper as it ought to be, and the horſes of courſe become diſeaſed, or where they are wrought too hard, or not kept ſufficiently to their labour, as well as where they are fed without regularity; the ſame thing muſt be the conſequence. In the beſt arable diſtricts in the northern parts of the kingdom, the methods of working and treating the labouring horſes are, at the time of the ſeeding, to increaſe the length of the time of working in the day, and to have recourſe to ſuch food as is of a better quality, than that which is uſually allowed during the winter ſeaſon. They are at this buſy period commonly foddered with hay or pea-ſtraw, with each half a peck at leaſt of dry clean oats, or theſe in mixture with peas or beans, as ſoon as they return from the field in the morning and evening; and a certain portion of the dreſſings of the corn in mixture with common or cut chaff, either well ſoaked in cold water, or boiled, is alſo given every forenoon and afternoon before the work is begun again. They are conſequently, during the laborious part of this intereſting ſeaſon, fed regularly four times in the day with corn. But in theſe northern parts of the iſland, inſtead of executing the whole of the diurnal labour conſtantly, in what is termed, in the ſouth, one journey; the farm horſes, from the middle of March to the end of September, make two journeys. This is conſidered by ſome as being a ſuperior mode of proceeding, in conſequence of the work being more divided, and the horſes reſting ſome hours in the moſt hot parts of the day.

During the ſummer, except in the time of labour, the team horſes are kept in the ſtable, and permitted to have as much cut clover as they can eat. But in the wheat ſeed ſeaſon, and at the time the grain is conveyed to the ſtack yard, a portion of corn is allowed, and which is continued in more full quantities, as long as the weather keeps ſuitable for the operations of the plough. In the winter ſeaſon, when the labour of the team is greatly diminiſhed, the horſes have ſtraw with about half a peck of corn in the day. But on ſome farms the allowance of corn is wholly withdrawn, and properly cleaned potatoes made uſe of in its place. It is conſtantly the practice to have theſe horſes carefully cleaned and dreſſed, and as much under the eye of the farmer as poſſible. See HORSE-KEEPER and TEAM.

It is neceſſary likewiſe to be very attentive to the feet and ſhoes of team horſes; and the improved methods of fixing and forming them ſhould he had recourſe to. Nothing ſhould be pared from the ſole or other parts except the rotten looſe matters. See SHOEING *of Horſes*.

Some attention is likewiſe neceſſary on firſt turning out horſes to graſs. It is probably the beſt practice to inure them to the change gradually, by only letting them remain in the field for a little while on their being newly put to the graſs; afterwards increaſing the length of their ſtay, as there may be occaſion. It is probably the beſt time to turn them out in the evening, though the uſual time is in the morning. See GRAZING and PASTURE.

HORSE, *Airing of a.* See AIRING.

HORSES, *Backing of.* The firſt backing of a horſe is a thing of great conſequence, as his value afterwards very much depends on it. After a colt has been exerciſed ſome time, morning and evening, and becomes ſomewhat obedient, he is to be taken to ſome ploughed lands, the lighter the better; he muſt be made to trot over theſe in the hand, by that means to tire him and abate his wantonneſs. When this is done, care muſt be taken that all the tackling be good and firm, and every thing in its due and proper place; then a perſon is to hold his head, and another to mount him; but this muſt not be done ſuddenly, or at a jerk, but very gradually and ſlowly, by ſeveral half riſings and heavings. If he bears this patiently, the perſon is to ſeat himſelf firmly on his back; but if he be troubleſome, and not tamed enough, the perſon is to forbear the attempt to mount, and he is to be trotted hard in the hand over the ſame ploughed lands again, till he is willing to receive the rider quietly on his back. When this is done, the perſon who is on his back muſt cheriſh him, and the man who has his head muſt lead him a few paces forward; then he is to be cheriſhed again. The feet are to be fitted well in the ſtirrups, and the toes turned out; afterwards the rider is to ſhrink and move himſelf in the ſaddle, and the perſon who holds his head is to withdraw his hand a little farther from the mouth. As the rider moves his toes forward, the holder muſt move him forward with the rein, till he is made to apprehend the rider's motion of body and foot, which muſt always go together, and with ſpirit, and will go forward without the other's aſſiſtance, and ſtay upon the reſtraint of the rider's hands.

When this is accompliſhed, let him be cheriſhed, and have graſs and bread to eat; and then let the rider mount and alight ſeveral times, cheriſhing him between each time: and thus he is to be managed till he will go on, or ſtand ſtill at pleaſure. This being done the long rein may be laid aſide, and the band about the neck, which are always uſed on this occaſion, and nothing will be neceſſary but the trenches and caveſon, with the martingal. A groom muſt lead the way before; or another horſe going only ſtraight forwards, and making him ſtand ſtill when deſired. In this manner, by ſometimes following, and ſometimes going before another horſe on the trot, the creature will by degrees be brought to know that it is his buſineſs to be quiet and governable. See FOAL.

HORSES, *Breeding of.* In order to have a good and beautiful race of horſes, it is neceſſary to chooſe for a ſtallion a fine barb, free from hereditary infirmities; ſuch as weak eyes, bad feet, ſpavins, purſineſs, or the like. Diſorders that ariſe from accidents are of no conſequence; nor is the horſe to be at all the leſs valued for them as a ſtallion. Three months before this horſe is to cover a mare, he ſhould be fed with ſound oats, peas, or beans, or with coarſe bread, and a little hay, but a good quantity of wheat ſtraw; he ſhould be led out twice a day to water all this time, and after every watering walked about an hour, but not over-heated. If he be not prepared and put in heart in this manner, the colts will be weakly, and the horſe himſelf will be ſpoiled, growing purſy and broken-winded.

If he is put to too many mares, he will not laſt long; his mane and tail will begin to fall off through weakneſs, and it will be difficult to get up his fleſh again by the next year. The number of mares ſhould be proportioned to his ſtrength, and twelve, fifteen, or at the moſt twenty, are as many as a horſe will well ſerve for in a ſeaſon. Mares go with foal eleven months, and as many days over as they are years old. This being certainly known, it is eaſy to contrive ſo that all the foals may be brought forth at a time when there is plenty of graſs. About the end of May the mares are to be put into an incloſure capable of feeding them as long as the ſtallion is to be with them, or that they are in ſeaſon. In this incloſure all the mares to be put together, as well thoſe which are barren as others. The ſtallion's hind ſhoes are to be taken off, but the fore-ſhoes ſhould be left on to preſerve his feet; then lead him forth, and let him cover a mare twice in hand, to render him more tame and gentle. After this take off the bridle and turn him looſe among the reſt, where he will become familiar with them, and not one of them will be horſed but when they are in ſeaſon. There ſhould be a little lodge built up in ſome part of the incloſure, and peas, beans, oats, bread, and other good food, put into the manger in it, that the horſe may retire into it in the ſcorching heats, and eat what he likes beſt. He muſt be thus entertained during the whole time he is with the mares, which is to be about ſix or ſeven weeks.

Mares that are very fat and groſs do not hold well; but thoſe which are moderately fat conceive with the greateſt ſucceſs and eaſe. To bring a mare in ſeaſon, it is a common thing to give her a quart of hemp-ſeed, or twice that quantity, night and morning, for eight days before ſhe is brought to the horſe. If ſhe refuſe it alone, it may be mixed with beans or oats, and will go down; and if the ſtallion eat of it alſo, it will make him the better.

The ſtallion ſhould not cover before he is ſix years old, nor after he is fifteen. A mare ſhould never be covered before ſhe is three years old; they ſhould be always ſound and healthful, and of a good breed; ſuch as theſe will bring forth better and finer foals than any others. The colts produced from theſe, are not to be uſed for ſtallions; for they will degenerate, and the race will ſoon become exactly our own country breed. If a barb is not to be had, a Spaniſh horſe is to be choſen. See MARE, and STALLION.

HORSES, *Diſeaſes of.* See BOTTS, CONSUMPTION, COUGH, FARCY, FEVER, GLANDERS, GRIPES, HORSE-*worm*, &c.

The horſe is likewiſe in ſome caſes ſubject to the ſtone.

HORSES, *Eyes of.* See EYES *of Horſes.*

HORSES, *Fattening of.* The being able to do this ſpeedily is one of the greateſt arts our dealers have, and indeed is one of the greateſt niceties in the whole management of theſe animals. Many methods have been preſcribed; but the following ſeems moſt to be depended on; take elecampane, cummin-ſeed, tamariſk, and aniſeed, of each two ounces; common groundſel, one handful; boil all theſe very well, with two handfuls of garlic, ſcraped and cleaned, in a gallon of good ale; ſtrain the liquor well off, and give the horſe a quart of it every morning made hot; keep him warm after it. After he has taken this for four or five mornings, he may be turned out to graſs, or kept in the houſe, as the ſeaſon will permit. But whenever provender is given him, a quantity of powder is to be prepared of equal parts of cummin-ſeeds and elecampane, and give him half an ounce of it every time, ſprinkling it in by degrees as he eats, that he may not nauſeate the whole.

If this method does not ſucceed in a ſhort time, then take two ſpoonfuls of diapente; brew it in a pint of ſweet wine, and give it the horſe for three mornings. This will take off any inward ſickneſs, and make the other things take effect. After this feed him with good provender three times a day; that is, after his watering in the morning, after his watering in the evening, and at nine o'clock at night. If he does not eat the provender well and freely, it muſt be changed for ſome other kind. If all this does not ſucceed, let the horſe be blooded; and then take half a buſhel of coarſe barley meal, put it into a pail-full of water, and ſtir the whole together very well; then let it ſettle by ſtanding. Pour off the clear liquor into another veſſel, and let him drink it for his common drink, and eat the remainder, which falls to the bottom of the pail. If he refuſe to eat this alone, there may be ſome bran mixed among it. This ſhould be given him three times a day, morning, noon, and night. If he does not rightly take to the meal with the bran, ſome oats muſt be mixed with it, and this will readily bring him to feed on it. But whichever way is uſed, they muſt be by degrees diminiſhed in quantity, till at length he is brought to eat the meal alone; for that is the thing that muſt fatten him up. Care muſt be taken that the barley is ground freſh every day as it is uſed, for it quickly grows ſour; and when this has once been the caſe with one parcel, no art will ever bring the horſe to touch any of it afterwards. Scarce any horſe but will be well fattened by keeping him to this diet for about twenty days.

Barley ground in this manner cools and purges the creature; but the greateſt efficacy, as to the fattening of him, lies in the water, which by this management takes up all the rich part of the barley into itſelf. When the horſe grows luſty on this diet, it muſt be taken from him by degrees, giving him at firſt oats once, and barley-meal twice a day; and then oats twice, and the barley-meal once, till he is perfectly weaned from it. In the mean time he muſt have good hay, and he muſt not be ridden; only it will be proper to walk him gently about an hour or two in the heat of the day. If it be found that the horſe wants a good ſmart purging during the time of his continuing on the barley-diet, the beſt time to give it him is after the firſt eight days, and the following is a very proper ſort of phyſic; take of the fineſt aloes one ounce, agaric, in powder, half an ounce; the powder of Florentine orrice, one ounce; let all theſe be mixed together, and put into a quart of milk, warm from the cow. This will work very briſkly; and after it is over, the uſual diet is to be continued. If horſes of value were to be kept to this diet once a year, it would make them leſs hot and dry, and not ſubject to many diſeaſes which they are troubled with at preſent, and would be particularly uſeful after campaigns and long journeys. If the horſe loſes his appetite by this diet, it will be proper to tie a chewing-ball to his bit, renewing it ſo often, till at length he begins to feed heartily on the barley; for theſe balls at once reſtore appetite, and are themſelves of a fattening nature. See CHEWING-*balls.*

HORSE *on a journey, Management of a.* The common method of travelling in England being on horſeback, it may be proper to give ſome general rules for keeping the creature ſound, and doing the buſineſs agreeably, without many of the accidents which uſually attend it.

Care muſt be taken that the ſhoes be not too ſtraight, and do not pinch the horſe's feet any way; but be well ſhaped, and fit eaſy. It is proper to have them put on freſh a few days before the journey, that they may laſt well, and that they may be ſettled to the feet before the ſetting out. The bridle is next to be examined ; that the bit of it be proper, and not too heavy ; for if it be, it will incline him to carry low when he grows tired, and reſt upon the rider's hand ; this is what they call the uſing a fifth leg. It is a very diſagreeable thing, but may often be avoided, only by taking a proper care of the bit. The mouth of the bit ſhould reſt upon his bars, about a finger's breadth from his tuſhes, ſo as not to make his lips uneaſy. The curb ſhould reſt in the hollow of his head, a little above the chin ; and if it gall him, the place muſt be defended with a piece of buff or other ſort of leather.

The next thing to be regarded is the ſaddle ; and proper care muſt be taken as to this, that it do not reſt either upon the withers, reins, or back-bone ; and that one part of it do not preſs upon the back, any more than another. Some riders gall a horſe's ſides below the ſaddle with their ſtirrup-leathers. This is moſt likely to happen to a lean horſe; and to prevent it a leather ſtrap ſhould be fixed between the points of the fore and hinder bow, of the ſaddle, and the ſtirrup-leathers ſhould be made to paſs over theſe leathers.

It is always beſt to begin a long journey by ſhort ſtages ; and this is the more neceſſary, if the horſe has not been exerciſed for ſome time before. If it be a horſe that is ridden, he ſhould be ſuffered to ſtale as often as he likes, and even invited to it ; but, if a mare, ſhe is to be leſs indulged in it as leſs neceſſary, and often diminiſhing her ſtrength. It is always adviſable to ride very ſoftly for a quarter of an hour, or half an hour before coming in to the inn at night, that the horſe may not be over-hot when put into the ſtable ; but if the haſte of the journey will not admit of this, the horſe ſhould be walked in ſome perſon's hands, to cool him gently before he is put up.

If the weather is cold, a cloth ſhould be laid over him while he is walked ; and when taken in, his whole body ſhould be rubbed and dried with ſtraw. Some have a cuſtom of ordering their horſes' legs to be rubbed well down, on their firſt coming in ; but this is very prejudicial while the horſe is hot, and ſhould always be let alone till he is perfectly cooled.

As ſoon as the horſe is cooled, and ceaſes to beat in the flanks, the bridle is to be taken off, the bit waſhed, and hay given him, that he may eat at pleaſure. The duſt in very dry weather will ſometimes clog up the tongue of the horſe in ſuch a manner, that he cannot eat without great difficulty ; in this caſe ſome bran and water ſhould be firſt given him to waſh his mouth, or the ſervant ſhould do it with a wetted ſpunge.

Theſe are the proper methods when the horſe has been rode moderately ; but when he has been hurried at a great rate, the ſaddle is to be taken off as ſoon as he is put up, and the ſweat rubbed off with a ſweat-knife ; and then the whole body and legs are to be rubbed carefully down, and the head is to be wiped with a cloth, as alſo the back under the ſaddle, and the thighs ; then the ſaddle ſhould be clapped on again, and the horſe gently led up and down, till cool and dry. The feet are alſo to be examined, to ſee if a ſhoe be wanting, or if any of them preſs upon the ſole ; and the dirt, gravel, or other foulneſs, is to be picked out from between the ſhoe and the foot. The openings of the feet may be ſtopped with cow-dung, and the hoofs, if brittle, ſhould be anointed with ſome fatty ſubſtance juſt at the ſetting on ; and in dry weather they ſhould be greaſed, not only at night, but noon. Many horſes, as ſoon as unbridled, will lay themſelves down, inſtead of eating.

Many are apt on this to ſuppoſe the horſe ſick ; but it is generally owing only to the heat and pain they find in their feet, which renders them unable to ſtand upon them. In this caſe, if their eyes are examined, they will be found briſk and good ; and the hay being offered them as they lie, they will eat it greedily. This ſhews there is no inward diſorder, and the heat and tenderneſs of the feet, if examined, will ſhew that they are the parts in pain. The principal thing to be done in this caſe, is taking care that the ſhoes do not reſt upon the ſoles. This is not eaſily known, but by taking off the ſhoes, which in caſes of extremity ſhould always be done ; it will then be found where the ſole is touched by the ſhoe, being in that part more ſmooth and ſhining than elſewhere. In this caſe the feet are to be pared in thoſe parts, and then the ſhoes are to be fixed on again, anointing the hoofs, and ſtopping the ſoles with hot black pitch or tar.

Theſe are the means by which travelling will be rendered eaſy and commodious both to the rider and the horſe ; but there is ſome care alſo to be taken of the creature, after he comes off from a long journey. The firſt thing to be done is to draw the two heel-nails of the fore-feet, and if the ſhoe be large, then four ſhould be drawn ; two or three days after the horſe ſhould be blooded, and for ten or twelve days after this he ſhould be fed with wet bran, without any oats ; but he is to be kept well littered. The reaſon of drawing the heel-nails is, that the feet are apt to ſwell after journeys ; and if this is not done, the ſhoes preſs upon them in that part, and become very uneaſy to them. It is adviſable to ſtop them alſo with cow-dung for ſome time ; but they are in the wrong who pare them down after taking off the ſhoes, for the humours being all in motion after this, they are apt to fall into the feet.

If there appear any danger of the creature's legs ſwelling after the journey, it may be eaſily prevented by this means : take a quantity of the dung of an ox or cow freſh made ; mix it with ſo much vinegar as will reduce it to a ſoft paſte, and add to it a handful of ſalt ; with this rub all the hips thoroughly up to the knees, and let it dry on ; give the water in a pail that evening, that the legs may not be wetted, and the next morning the horſe is to be led to water, and the whole remaining matter waſhed of. The jockies have a very cunning trick to recover the hoofs of a horſe injured by a long journey : they make a hole in the foot, and fill it with moiſtened cow-dung ; they keep this in it a month, and the continual moiſture occaſioned by it makes the hoof grow very quick, and ſoon recover the proper dimenſions ; but it ſoon after dries and ſhrinks ſo, that the foot is ſtraightened, and the whole hoof becomes brittle.

Cow-dung, applied to a horſe's foot, always moiſtens the ſole ; but it dries up the hoof if continued any length of time to it. The beſt method of recovering a horſe's hoofs, is to make a hole in the ſtable floor, filled with blue clay a little wetted ; in this the horſe ſhould keep his fore-feet a month ; this will have more effect than a ſmall portion of cow-dung in the foot ; and the effect will be of ſo different a nature, that the hoof will be rendered more tough than before, inſtead of being made brittle by it.

Moſt horſes that are fatigued, or overworked by long journies, have the flanks altered by it, without being purſy ; eſpecially horſes naturally vigorous, which have been worked too violently. The beſt remedy in this caſe, is to give the horſe half a pound of honey in the morning, mixed among a feed of ſcalded bran : if he eats the half pound readily, give him a pound the next morning : continue this till the honey ceaſes to purge the creature ; after this, powder of liquorice may be added to the ſcalded bran, and this continued ſome time, and two or three glyſters, at convenient diſtances of time, will be found very ſerviceable. If the horſe be very lean, it will be proper to give him ſome wet bran over and above his proportion of oats ; and graſs is alſo very proper, if the creature be not inclined to be purſy. This caution, however, is to be had at all times, that exceſſive feeding may be bad, by ſubjecting the horſe to the farcy. When the horſe begins to drink heartily, it is a ſign that he will ſoon recover. Though this ſometimes fails, it is a good general rule.

When a horſe comes tired into a ſtable, freſh litter has the virtue always to occaſion him immediately to ſtale. This is known to be a very great advantage to a horſe in a tired ſtate ; and when the litter is old and dirty, it never has any ſuch effect upon him. If the owners knew how refreſhing it is to a horſe to diſcharge his urine on his return from labour, they would be more careful in giving him all means and occaſions of it than they are. This ſtaling after fatigue prevents thoſe obſtructions in the neck of the bladder or urinary paſſages, which horſes are too ſubject to ; the bladder being often inflamed by the long retention of the heated urine in it, and the creature periſhing by it. Some of our farmers act wrong in this caſe of the litter, not through careleſsneſs or accident, but by principle ; they order the old litter to be left a long time in the ſtables, that it may be impregnated with more and more of the urine, &c. of the animal, and be made richer for the fields. It is not to be doubted but the manure is greatly improved by this ; but the damage done to the horſe by it, is greatly over-proportioned to the benefit. The heat which the dung acquires, by thus lying together, ſpoils the feet of the creature, and makes it unfit for any ſervice, and occaſions many diſtempers, which are ignorantly continued and increaſed by the continual addition of heat in the fermenting dung, till at length the horſe periſhes.

Thoſe who have any concern with horſes know, that it is ſometimes very difficult to make them lie down in the ſtable. The following ſimple method is propoſed for this purpoſe by a noted dealer. When you have a mind to make him lie down, take a piece of ſtrong pack-thread, or a cord, and tie it as tight round the horſe's tail as poſſible, without breaking the ſkin, and as near as you can to the rump-bone : this will give him a pain in the back, and he will be glad to change his poſture, to get eaſe ; and when he finds he cannot in any other way procure it, he will lie down, which he will find the moſt eaſy poſture, and he will of courſe take a liking to it.

Horses, *Watering of.* Whilſt a perſon is on a journey, the horſe ſhould always be ſuffered to drink of the firſt good water he comes to after ſeven o'clock in the morning in ſummer, and after nine or ten in the winter. Moderately pure water is to be preferred, that being beſt of all which is neither too clear nor penetrating, nor muddy and ſtinking.

Though it is the cuſtom in England to run and gallop horſes after drinking, which we call *watering courſes*, and which we ſuppoſe brings them into wind, yet Sollyſel, and many other of the beſt judges of horſes, tell us, that it is one of the worſt and moſt pernicious practices that we can be guilty of ; no good can accrue from it, and many horſes are rendered purſy by it.

While a horſe is drinking, the rider ſhould draw up his head five or ſix times, making him move a little between every draught. The rider need not be afraid of giving him water, with proper moderation, even in almoſt any circumſtances. If he be warm and ſweat very much, yet if he is not quite out of breath, and there are four or five miles to ride, he will be better after drinking a little, than if he had drank none at all ; only obſerving, that if the horſe were very warm at his going into the water, his pace muſt not be leſs than a moderate trot when he comes out, that he may not be chilled.

In the time of a journey the horſe ought to be ſuffered to drink in this manner of the waters that come in the way, as often as may be ; for if the rider happens to bait when he is hot and ſweaty, he muſt not be ſuffered to drink for a long time, as it would endanger his life ; and if he has not been watered in this manner on the road, his exceſſive thirſt will often prevent his eating, and he will not be able to touch any ſort of food for an hour or two, which is uſually more time than the rider can ſtay : and yet without eating at baiting times, he will not have ſtrength to go on. The giving him water on the road will, on the contrary, keep him ready for food whenever it is offered him, and the rider need ſtay no longer than his own refreſhment requires, the horſe eating immediately, and being readily qualified to go on again.

If there be any ſhallow water in the way a little before the coming to the inn where the horſe is to reſt all night, it is always proper to ride him in, and not only give him a little drink, but ride him about ſeveral times, not quite up to the belly ; this will clean his legs, and prevent humours from falling down into them. If the horſe be very warm, and there has been no convenience of watering him upon the road, the oats that are given him ſhould be firſt ſteeped a-while in ale ; this will induce him to eat, though he could not have touched any that were wholly dry.

Many are of opinion that horſes are ſometimes ſpoiled by giving them oats before their water ; but Mr. Sollyſel affirms, that though it be not the cuſtom to give oats till afterwards, yet it never does any harm to feed the horſe with them both before and after drinking ; and that it is often proper and neceſſary, eſpecially when the horſe has been hard rid, and is warm.

Horse, *Draught*, in *Farming*, a ſort of coarſe-made horſe deſtined for the ſervice of the cart or plough. In the choice of theſe horſes for what is called the ſlow draught, they are to be ſelected of an ordinary height, for otherwiſe when put into the cart one draws unequally with the other. The draught-horſe ſhould be large bodied and ſtrong-loined, and of ſuch a diſpoſition, as rather to be too dull than too briſk, and rather to crave the whip than to draw more than is needful. Mares are the fitteſt for this uſe for the farmer, as as they will be kept cheap, and not only do the work, but be kept breeding, and give a yearly increaſe of a foal. They ſhould have a good head, neck, breaſt, and ſhoulders ; for the reſt of the ſhape it is not of much conſequence. Only, for breeding, the mare ſhould have a large belly ; for the more room a foal has in the dam, the better proportioned it will be. Draught-horſes ſhould be always kept to that employ. Some put them to the ſaddle on occaſion, but it does them great harm, alters their pace, and ſpoils them for labour. The draught-horſe ought to have a large broad head, becauſe horſes of this ſhaped head are leſs ſubject than others to diſeaſes of the eyes. The ears ſhould be ſmall, ſtraight, and upright ; the noſtrils large and open, that he may breathe with the more freedom. A horſe with a full and bold eye always promiſes well. On the other hand, a ſunk eye and an elevated brow are bad ſigns. The horſe is eſteemed fitteſt for this purpoſe alſo, that has a large and round buttock, which neither ſinks down nor cuts. He muſt have a firm and ſtrong tail, and the dock muſt be thick and well furniſhed with hair, and placed neither very high nor very low. The legs ſhould be rather flat and broad than round : the roundneſs of the leg being a fault in a horſe deſtined to labour, that will ſoon ruin him. As to the hinder legs, the thighs ſhould be fleſhy and long, and the whole muſcle which ſhews itſelf on the outſide of the thigh ſhould be large and very thick. No country can bring a parallel to the ſize and ſtrength of our horſes deſtined for the draught. In London there are inſtances of ſingle horſes that are able to draw on a plain, for a ſmall ſpace, the weight of three tons, and which can with eaſe, and for continuance, draw half that weight. The pack horſes of Yorkſhire uſually carry a burden of four hundred and twenty pounds, over the higheſt hills of the north, as well as the moſt level roads: but the moſt remarkable proof of the ſtrength of our Britiſh horſes is derived from that of our mill-horſes; ſome of which will, at one load, carry thirteen meaſures, which, at a moderate computation of ſeventy pounds each, will amount to nine hundred and ten pounds. Nothing is ſo eſſential to the health of theſe ſerviceable creatures as cleanlineſs; if they are fed ever ſo well, and not kept clean, they will be ſubject to numerous diſeaſes.

The ſervant who has the care of them ought to be up very early, and to clean the racks and mangers from all filth. The currying of them ought to be carefully performed every morning, but not in the ſtable, for the duſt to fall upon the other horſes, as is too often done. After the horſes are duſted, they ſhould daily twiſt a whiſp of ſtraw hard up, and wetting it in water, rub the legs, ſhoulders, and body with it. Many of the diſeaſes of draught-horſes, which are not owing to naſtineſs, are owing to bad water; ſuch as is too raw, too muddy, or too cold, being all improper. If there be any running ſtream in the neighbourhood, they ſhould always be led to that to water, every day in ſummer, but in winter, well-water is warmiſh, and is better for them. If there be a neceſſity of giving them well-water in ſummer, it muſt be drawn up ſome hours before the time, and expoſed to the ſun-beams in tubs or troughs; marſh-water, or that of lowland ditches, is worſt of all. When the labouring horſe has drank his water, he ſhould have his oats given him, and theſe ſhould be carefully ſifted, and the manger duſted firſt. It is a common practice as ſoon as a horſe is come in from his work, to rub down his legs with a hard whiſp of hay, but the beſt judges of horſes abſolutely condemn this, and obſerve, that this rubbing of the legs after hard labour, brings down humours into them, and makes them ſtiff.

The rubbing itſelf is wholeſome, but the doing it when the creature is hot is the miſchief; while a horſe is in a ſweat it is a great relief and refreſhment to him to have his body rubbed down, but when he is cold is the proper time to rub his legs. The racks are to be well ſupplied with hay, and the horſes ſhould be left to reſt and eat, about two hours, and then led to water; after this their oats ſhould be given them, and they ſhould then go to work again.

In the evening, when the labour of the day is over, the firſt thing to be done, is to examine the feet, and ſee if any thing is amiſs about the ſhoes, and what earth or gravel is lodged in the foot, between the ſhoe and the ſole, is to be picked out, and ſome freſh cow-dung put in its place, which will cool and refreſh the part.

A very material thing for the preſervation of all ſorts of cattle, but of none ſo much as draught-horſes, is freſh and clean litter.

Horse, *Hunting*. See Hunter.

Horse, *Race*. See Racing.

Horse, *Stone*. See Stallion.

Horse, *War*. The proper rules for chuſing a horſe for ſervice in war are theſe; he ſhould be tall in ſtature; with a comely head, and outſwelling forehead. His eye ſhould be bright and ſparkling, and the white part of it covered by the eye-brow. The ears ſhould be ſmall, thin, ſhort, and pricking; or, if long, they ſhould be moveable with eaſe, and well carried. The neck ſhould be deep, and the breaſt large and ſwelling. The ribs bending, the chine broad and ſtraight, and the buttocks round and full. The tail ſhould be high and broad, neither too thick nor too thin; the thigh ſwelling; the leg broad and flat, and the paſtern ſhort. When ſuch a horſe is choſen, he muſt be kept high during the time of his teaching, that he may be full of vigour. His food muſt be ſweet hay, and good clean oats, or two parts of oats, and one part of beans or peas, well dried and hardened. The quantity ſhould be half a peck in the morning, and the ſame quantity at noon, and in the evening. Upon his reſting days he is to be dreſſed between five and ſix in the morning, and watered at ſeven or eight. In the evening he is to be dreſſed at four, and watered about five, and he muſt always have provender given him after watering; he muſt be littered about eight, and then muſt have food given him for all night.

The night before he is ridden all his hay is to be taken away about nine o'clock, and he muſt have a handful or two of oats about four in the morning; when he has eaten theſe, he is to be turned upon the ſnaffle, and rubbed very well with dry cloths; then ſaddled, and made fit for his exerciſe. When he has performed this, he is to be brought ſweating into the ſtable, and rubbed down with dry whiſps. When this has been done, the ſaddle is to be taken off, and he is to be rubbed down with dry cloths; the houſing-cloth is then to be laid on, and the ſaddle being again laid on, he is to be walked gently about till thoroughly cool. After this, he muſt ſtand without meat two or three hours, then he muſt be fed; and in the afternoon he is to be rubbed and dreſſed as before, and watered in the uſual manner.

Horse, *River*, in *Zoology*. See Hippopotamus.

Horse, *Sea*. See Hippocampus.

Horse is alſo uſed, in the *Military Language*, to expreſs the cavalry (ſee Cavalry); or the body of ſoldiers who ſerve on horſeback.

The horſe includes horſe guards, horſe grenadiers, and troopers. Dragoons are alſo frequently comprehended under this name, though they fight on foot as well as on horſeback. See Dragoons, Grenadiers, and Guards.

Horſe guards, by the Spaniards called *guardas a cavallo;* by the French, *gardes de corps;* by the Engliſh uſually *life-guards;* are the guards of the king's perſon and body.

The duty is, by parties from the guard, to attend the king's perſon when he goes out near home; an honour which has been lately appropriated to the *light-horſe*. On ſtate-days he is attended by detachments out of the horſe and grenadier guards.

One of three captains of the horſe-guards attends on the king when he walks on foot, immediately next his perſon; carrying in his hand an ebony ſtaff, or truncheon, with a gold head.

Horse-*Artillery*, a comparatively novel inſtitution in the *Military Art*, by which the force of cavalry and ordnance is united with the moſt rapid movements, executed with machines that were once ſo cumbrous. This new artillery is organized on ſuch principles as to perform movements the moſt rapid and the moſt unexpected. Thus it can proceed with celerity either to a point threatened by the enemy, or a poſt which, by a deciſive attack, it is intended to carry; follow the horſe every where, if needful, and bruſh the enemy by the combined effect of all the means of attack and defence which the theory of the military art, judgment, and experience can ſuggeſt.

In the campaigns of 1757-8-9 againſt the Ruſſians, it often happened that the Pruſſian light-horſe, at the very moment when they imagined themſelves to be ſure of ſucceſs, met with a battery of cannon, though no infantry were preſent, which led them to ſuppoſe that the Ruſſians had horſe-artillery, able to follow all the movements of the horſe. The fact being aſcertained, Frederic the Great introduced this artillery into his army in the ſpring of 1759, at his head-quarters at Reichennendorff, near Landſhut, where every morning he exerciſed this new corps himſelf, and directed its manœuvres. The king alſo made a ſucceſsful trial with his horſe-artillery before he left that camp, by covering it with a reconnoitring party beyond Liebau, on the retreat of his dragoons, in a manner ſo effectual, that all the attacks of the enemy's horſe, though far ſuperior in number, completely failed. The Auſtrians were the firſt who inſtituted this new military eſtabliſhment: in 1783 they manœuvred with horſe-artillery near Prague; and ſince that time, it has been introduced into the Britiſh, Swediſh, Saxon, and Hanoverian armies; yet with conſiderable difference as to the calibre of the ordnance, and the way of mounting the artillery-men. The Pruſſian horſe artillery conſiſts of ſix-pounders, the Auſtrian of light three-pounders, the Hanoverian of heavy three-pounders, the Daniſh of one-pounders, &c. The Pruſſian artillery-men are on horſe-back; the Auſtrians ride on the carriages of the guns; the Hanoverian party ride partly on horſe-back, partly on the gun-carriages, wurſts, &c. But no European power has hitherto derived ſuch important advantages from this new artillery as France, where it was introduced in the year 1792, and ſoon carried to great perfection. In order to give it the advantage of a ſuperior fire, the French flying, or horſe artillery conſiſts of eight-pounders, and ſix-inch howitzers; the ammunition is carried in light caiſſons, and moſt of the artillery-men are mounted, whilſt others ride on the wurſts. By this arrangement, in addition to the known abilities of the French cannoneers, the Republican horſe-artillery ſoon acquired a decided ſuperiority over that of the Auſtrians, and maintained it during the whole war. The formation of the horſe-artillery in France took place in the year 1791, under royal orders carried into effect by M. Duportail, miniſter at war, who directed that two companies of artillery-men ſhould be eſtabliſhed by the commandant of the military diviſion at Mentz: and a ſhort time before the declaration of war in 1792, M. de Narbonne, who had ſucceeded M. Duportail, aſſembled a military committee, conſiſting of the moſt experienced officers in the artillery and engineer departments, aided by the advice of the generals commanding the three grand diviſions of the whole French army, and iſſued a number of reſolutions for giving effect to this inſtitution. It was determined, that with reſpect to the mode of being armed, equipped, accoutred, &c. the mounted artillery was to differ from the field ordnance only by the rapidity of its movement; on this account the horſes were to be ſtrong and active; and moreover it was conſidered moſt advantageous to the ſervice to mount the cannoneers on horſe-back, in preference to artillery carts; and that without abſolutely excluding pieces of larger calibre, eight or twelve pounders and howitzers ſeemed beſt adapted to the nature of this ſervice. It was alſo reſolved that it would be ſuperfluous to drill the mounted artillery-man, ſo as to make him maſter of all the cavalry manœuvres; it being thought fully ſufficient for him to ſit his horſe well, to be able to mount and diſmount with eaſe and celerity, to guide his horſe according to the poſition of his piece, and to leave it entirely to his own judgment to act with the cavalry, ſhould he find himſelf involved in their manœuvres.

The Britiſh government, which was among the firſt in adopting this military inſtitution, eſtabliſhed a brigade of ſix troops of horſe-artillery, conſiſting of a colonel, two lieutenant-colonels, one major, ſix captains, ſix captain-lieutenants, twelve firſt lieutenants, ſix ſecond lieutenants, one adjutant, one quarter-maſter, one ſurgeon four aſſiſtant-ſurgeons, one riding-maſter, ſix ſerjeant-majors, ſeven quarter-maſter-ſerjeants, eighteen ſerjeants, eighteen corporals, forty-two bombardiers, five hundred and eighty-two gunners, four hundred and twenty-ſix gunner-drivers, twenty-four farriers, ſix ſmiths, twelve collar-makers, ſix wheelers, ſix trumpeters, ſix hundred and eighteen riding-horſes, and eight hundred and fifty-eight draft-horſes.

Horse, *Hungarian.* See Cavalry and Hussars.

Horse, *Light.* See Cavalry.

Horse, *Maſter of the.* See Master *of the Horſe.*

Horse is alſo a term uſed in various arts and manufactories, for ſomething that helps to ſuſtain their work from the ground, for the more commodious working at it.

The horſe uſed by tanners and ſkinners, alſo called the *leg*, is a piece of wood cut hollow and roundiſh, four or five feet long, and placed aſlope; upon which they pare their ſkins to get off the dirt, hair, fleſh, &c.

Horse is alſo uſed, in *Carpentry*, for a piece of wood jointed acroſs two other perpendicular ones, to ſuſtain the boards, planks, &c. which make bridges over ſmall rivers; and on divers other occaſions.

Horse, in *Mining*, is one of the very numerous deſignations which have been given by practical men to the fiſſures and diſlocations of the ſtrata met with in coal-pits and other mines. See Fault.

Horse, in *Rural Economy*, the name of a ſort of wooden frame ſtrongly put together, for the purpoſe of ſawing and cutting wood upon.

Horse, in *Sea Language*, is the name of a rope reaching from the middle of a yard to its extremity, or what is called the yard-arm, and depending about two or three feet under the yard, for the ſailors to tread upon, whilſt they are looſing, reefing, or furling the ſails, rigging out the ſtudding-ſail-booms, &c. In order, therefore, to keep the horſe more parallel to the yard, it is uſually ſuſpended to it, at proper diſtances by certain ropes called *ſtirrups*, which hang about two feet under the yard, having an eye in their lower ends through which the horſe paſſes.

Horse is alſo a thick rope extended in a perpendicular direction near the fore or after-ſide of a maſt, for the purpoſe of hoiſting or extending ſome ſail upon it. When it is fixed before a maſt, it is calculated for the uſe of a ſail called the ſquare-ſail, whoſe yard being attached to the horſe, by means of a traveller, or bull's eye, which ſlides up and down occaſionally, is retained in a ſteady poſition; either when the ſail is ſet, or whilſt it is hoiſting or lowering. When the horſe is placed abaft or behind a maſt, it is intended for the try-ſail of a ſnow, and is accordingly very rarely fixed in this poſition, except in thoſe ſloops of war which occaſionally aſſume the form of ſnows, in order to deceive the enemy. Falconer's Mar. Dict.

Horse is alſo a cant name introduced into the management of lotteries, for the chance or benefit of a ticket, or number, for one or more days, upon condition, if it be drawn a prize within the time covenanted for, of returning to the ſeller an undrawn ticket.

To determine the value of a horſe.—Multiply the amount of the prizes in the lottery by the time the horſe is hired for; and from the product ſubtract the amount of the number of prizes by the value of an undrawn ticket into the time of the horſe: the remainder being divided by the number of tickets into the whole time of drawing, the quotient is the value of the horſe. See Lottery

Horse-*back*, in *Mining*, is applied to the humps or ſwellings on the top of ſome particular ſtrata, which are ſubject to ſuch anomalies, and which are alſo called bumps, ridges &c.

Horse *Bean*, in *Gardening*. See Bean.

Horse *Beech*. See Carpinus.

Horse *Bones, Foſſil*, in *Natural Hiſtory*. In digging in the peat and ſilt of fens and marſhes, it is not very uncommon to meet with the ſkulls and bones of horſes, as in Hatfield chace, in Yorkſhire, and the Iſle of Dogs, in Middleſex. (Parkinſon's Organic Remains, vol. i. p. 67 and 95.) The great comparative anatomiſt, M. Cuvier, in a Memoir on this ſubject, in the Ann. de Muſéum, tome xiv. page 33, or Philoſophical Magazine, vol. xxxv. p. 216, after mentioning a great number of inſtances and ſpecimens preſerved, of the bones of horſes which had been dug up, both in modern alluvial flats, and alſo in quarries accompanied by the bones of unknown and extinct animals, gives the oſteological characters of the horſe, and confeſſes that though they may ſerve to diſtinguiſh the modern or peat foſſils, they are inſufficient for determining, in moſt inſtances which occur, to what ſpecies, or whether to any of the known ſpecies of the genus equus, the foſſil remains in the ſtrata are to be referred. (See Phil. Mag. vol. xxxv. p. 388.) The pretended bones of a horſe found in the alum-works of Saltwick, and mentioned by Mr. Charlton in his "Hiſtory of Whitby," p. 355, were probably thoſe of an extinct animal.

Horse *bramble*, in *Agriculture*, a common name often applied to the briar or wild roſe of the field.

Horse-*bread*. Bread of a proper kind is often given to horſes to hearten and ſtrengthen them when they have gone through great fatigues, or are to prepare for ſuch. Common houſhold-bread will anſwer the purpoſe, but the more common way is to prepare a kind of bread on purpoſe. There are two different receipts for making this ſort of bread, each of which has its admirers. The firſt method is this: take wheat-meal, oat-meal, and beans ground fine, of each half a peck; aniſeed, two ounces; gentian and fenugreek-ſeed, of each an ounce; liquorice, two ounces: let all theſe be made into a fine powder, and ſifted together, that they may be perfectly mixed; then add the whites of twenty new-laid eggs, and as much fine ale as will knead the whole into dough. This is to be made into loaves, and well baked, but not burnt; and the horſe is to have a good quantity of it every morning for five or ſix days, without any other provender.

The other method is much nicer, but perhaps does not any way better anſwer the intended purpoſe of heartening up the creature. It is this: take wheat-meal, rye-meal, bean-meal, and oat-meal, of each half a peck; aniſeed and liquorice, of each an ounce; white ſugar-candy, four ounces: beat all theſe into powder, and ſift them together; then add the whites and yolks of twenty new-laid eggs, and as much white-wine as will make the whole into a dough. Let this be made into great loaves, and well baked; it muſt not be given the horſe too new, but when it has ſtood about three days it may begin to be uſed; the outſide is always to be chipped off when any of it is given. Theſe are the two ſorts of bread uſually given to prepare horſes for long journies. But there are three other receipts for making bread for race-horſes, which are as much eſteemed, and are given by our expert jockies for the ſecond, third, and fourth fortnight's feed. The firſt kind is made in this manner: take three pecks of clean beans, and one peck of fine wheat; let theſe be ground together, and kneaded into dough, with a large quantity of freſh barm or yeaſt, but with as little water as may be: when this has heaved and worked up a little, let it be kneaded again, and then made into large loaves and carefully baked; when three days old it may be given to the horſe, but not ſooner.

The ſecond ſort is to be made as the other, only with equal quantities of beans and wheat, and the cruſt of this is to be cut quite away before it is eat. This is to be given to the horſe at his uſual meals, either alone, or mixed with oats and ſplit beans.

The third ſort of bread is ſtronger than either of the others, and is to be made thus: take three pecks of wheat, and one of beans; let them be ground together, and made into very fine flour; knead this up into dough with a good quantity of yeaſt diſſolved in as much ſtrong ale as is neceſſary; add the whites of twenty eggs, and make the whole into large loaves. Theſe muſt be thoroughly baked, and when they have ſtood three days, the cruſt muſt be cut off, and the crumb only given, either alone, or mixed with oats or ſplit beans. This is to be the food for the laſt fortnight.

Horse *Cheſnut*, in *Gardening*. See Æsculus and Chesnut *Tree*.

Horse *Cheſnut, Petrified*, in *Natural Hiſtory*. In that fruitful ſoil for vegetable reſemblances, the pyritic cliffs of the upper part of the London clay in Sheppy iſland, in the Thames, Mr. Jacob mentions a nut reſembling the horſe-cheſnut of America: the reality of its being a nut of any kind is much to be queſtioned, from the circumſtances attending it.

Horse *Courſe*. See Hippodrome.

Horse-*dung*, in *Agriculture* and *Gardening*, the name of that ſort which is produced by the horſe in the ſtable or other place. As it exiſts in theſe ſituations it is generally much blended and intermixed with different ſorts of ſtrawy materials, which, from their diſpoſing the dung to take on heat more readily, render it of great utility in different views of field and garden culture. It is this property of running ſpeedily into the ſtate of fermentation that makes it ſo uſeful in the forming of hot-beds in the gardens, in order to raiſe ſeveral different early productions of the culinary kind, as well as many tender plants of other deſcriptions.

That which is the moſt proper for this uſe, in general, is ſuch as has continued together in the common dunghill until a conſiderable heap has been formed; and where it has already commenced the incipient ſtage of fermentation, and is become either wholly or partially moiſt warm, and capable of ſending forth ſome degree of ſteam, it is ſtill more ſuitable for the purpoſe. When, on turning it up with the fork, it puts on a ſort of blackiſh appearance, and is dry without being rotten or exhauſted, and abounds with a freſh ſubſtantial material that has a lively, moiſt, ſteamy warmth, it is in the moſt proper condition for the conſtruction of hot-beds. But dung that is of a freſher quality, yet moiſt and full of ſteamy litter, is highly deſirable, as it is readily capable of being brought into the proper ſtate. With this raw ſort, the beſt plan is to have it thrown up and well mixed together, before it be employed in conſtituting the hot-beds.

Where it is intended to be uſed merely as manure, whether in the field, or the garden, it is the moſt proper for almoſt every kind of crop, when it has paſſed into a conſiderably more reduced ſtate, and is become more ſoft and more imbued with moiſture. On this account, it is found extremely uſeful in raiſing various ſorts of culinary vegetables in the open ground, after it has been employed in the forcing-frames, or other hot-bed culture. It is eſſential, in all large gardens, to have full ſupplies of this ſort of materials always at hand during the ſeaſons at which it is likely to be wanted. See Dung, Hot-*bed*, and Manure.

Horse-*engine*, in *Mining*, is applied to the gins which are uſed at ſome of the lead-mines, ſimilar to thoſe of the coal-mines for drawing their ore and vein-ſtuff, and their water alſo, in barrels, in ſome few inſtances. See Winding *Engine*.

Horse-*fly*, in *Entomology*. See Hippobosca *Equina*.

Horse-*gin* is a vertical axle and large cylinder or drum, turned by horſes, for drawing coals or ores from pits or mines, &c. See Winding *Engine*.

Horse-*gold*, in *Mining*, is in ſome diſtricts uſed to denote the hematites, or yellow pyrites.

Horse-*hairs, animated*, a term uſed to expreſs a ſort of long and ſlender water-worm, of a blackiſh colour, and ſo much reſembling a horſe-hair, that it is generally, by the vulgar, ſuppoſed to be the hair fallen from a horſe's mane into the water as he drinks, and there animated by ſome ſtrange power. Dr. Liſter has at large confuted this abſurd opinion, in the Philoſophical Tranſactions. See Amphisbæna *aquatica*.

Horse-*hair-worms*. See Amphisbæna.

Horse-*heal*, in *Botany*. See Star *wort*.

Horse-*hoe*, in *Rural Economy*, a name given to that ſort of hoe, which is drawn by the labour of the horſe. See Hoe.

Horse-*hoeing*, a term ſignifying the operation of ſtirring, breaking down, and cultivating the ſoil, between the rows of grain, and other kinds of crops, by the uſe of the horſe-hoe. See Hoeing.

Horse-*iſland*, in *Geography*, a ſmall iſland of Scotland, in the Frith of Clyde, near the coaſt of Ayrſhire. N lat. 55° 41′. W. long. 4° 52′.

Horse-*iſlands*, a cluſter of ſmall iſlands near the E. coaſt of Newfoundland. N. lat. 50° 25′. W. long. 55° 30′.

Horse-*keeper*, in *Agriculture*, a name applied to the perſon, or ſervant, who has the charge of keeping, and looking after, team or other horſes. It is neceſſary he ſhould be well qualified for his buſineſs, as without a ſteady regular horſe-keeper, the farmer may ſuſtain great injury and loſs in various ways; while, with a proper manager, his ſavings may be conſiderable, without the condition of the animals being in the leaſt impaired. It forms part of the conſtant attention of the horſe-keeper to ſee that the horſes of which he has the charge, are properly cleaned, watered, and fed as ſoon as they return from their labour, and that their feet be well cleared beneath the ſhoe, by the picker, from all ſorts of little ſtones and earthy matters. The ſhoes ſhould likewiſe be carefully examined, to ſee that they are perfectly faſt and in order. Good ſhoes uſually laſt ſomething more than a month. It is alſo proper for this perſon to take care that they have plenty of litter, and that it be properly applied, as well as that their feeds of oats and cut meat be given them in a regular manner, and in ſufficient quantities. The uſual periods of feeding with grain are morning, noon, and night, and the proportion for each horſe, each time, from a quarter to half a peck, with frequently about two handfuls of beans, and ſometimes cut chaff. The oats ſhould be well ſifted, to clear them from duſt, ſand, &c. It is neceſſary, in addition, to let them have water twice, or oftener in the courſe of the day. See Team.

Another part of the duty of the horſe keeper is, that of taking care of, and keeping the harneſs, &c. in proper order. This is done by preſerving them conſtantly clean and well oiled. When not in uſe, they ſhould always be hung up carefully in their proper room or place after having the dirt, &c. well cleaned from them.

Horse-*knobs*, a common name frequently applied to knob or knap weed.

Horse-*leech*, in *Zoology*. See Hirudo *ſanguiſuga*.

Horse-*line*, in *Nautical Affairs*, ſignifies the long line or rope uſed for towing or dragging of barges or boats on navigable rivers and canals; it is uſually faſtened to the top of the maſt on wide rivers, and to the top of a ſhort maſt in canal-boats, called the chock, which can paſs under the bridges, and from which the line can readily be unhooked or caſt off by the boat man, to paſs bridges which have no towing path under them. See Canal.

Horse-*load*, is a denomination of a meaſure or quantity in ſeveral different counties, chiefly of corn or lime. At Lancaſter the load of barley is 6 buſhels, of oats $7\frac{1}{2}$ buſhels, and of wheat, beans, or peas $4\frac{1}{2}$ buſhels; at Mancheſter the load of beans is 5 buſhels, and of oats 9 buſhels; at Ulverſtone a load of oats is 6 buſhels, and of wheat $4\frac{1}{2}$. In moſt parts of Derbyſhire a load of corn is 8 buſhels; in many places the load or weight is five buſhels. A load of lime in Derbyſhire is 3 heaped buſhels.

Horse-*mackarel*, in *Ichthyology*. See Scomber *trachurus*, or Scad.

Horse-*meaſure*, that ſort of meaſure which is employed to aſcertain the heights of horſes, which is done by a ſort of box rod, ſo contrived as to ſlide out of a cane, having a ſquare at the end, which is divided into hands and inches, by which a horſe, or any other animal, may be meaſured.

Horse-*mint*. See Mint.

Horse-*muſcle*. See Muscle.

Horse-*muſcle Shells*, in *Natural Hiſtory*. The late Mr. Whitehurſt, in deſcribing the ſtrata of Derbyſhire, Inquiry concerning the Earth, p. 208. 2d edit., mentions the ſhells of freſh water horſe muſcles, as found in abundance in a thin ſtratum of iron-ſtone. Mr. William Martin, in his Petrificata Derbienſia, plate 27, figures and deſcribes this ſhell, and denominates it the mya ovata of Dr. Maton; it has been ſaid, however, by competent judges, that the above authors were influenced too much by their theory of the coal-meaſures being formed in *freſh water*, and that the reſemblance is not exact between the ſhells of the muſcle-band iron-ſtone, or iron-ſtone marble, (the courſe of which, through Derbyſhire and into Yorkſhire, is deſcribed in Mr. Farey's Report, vol. i.) and any recent or known ſhells whatever.

Horse-*path*, in *Engineery*, is ſometimes applied to the towing-path which is conſtructed by the ſide of all canals, and by narrow navigable rivers, for the uſe of the towing or track horſes. See Hauling *way*.

Horse *power*, in *Mechanics*. Among practical mechanics it has been uſual, of late years, to eſtimate the power of large machines and engines by the number of horſes to whoſe work they are equivalent, applied to a horſe-wheel, during a given time. This term was introduced when ſteam-engines firſt began to ſuperſede horſe-mills, in ſuch numerous branches of Engliſh manufactures, and when it was natural for the manufacturer to enquire how many horſes a ſteam engine would diſpenſe with in his works, and at what firſt coſt of erection, and per annum in coals, attendance, and repairs afterwards. Meſſrs. Bolton and Watt's preſent eſtimate of this power is, as we are informed, 32,000lb. raiſed one foot per minute; the late Mr. Francis Thompſon of Aſhover, Derbyſhire, who erected a good many engines, uſed to eſtimate it at 33,000lb. Deſagulier's experiments, when thus reduced, give 22,000lb.; and another experiment 27,500lb. ; thoſe of Mr. Samuel Moor, the late ſecretary to the Society of Arts, give 21,120lb. ; Mr. Olinthus Gregory, in his Mechanics, ſtates 18,480lb. ; Mr. James Watt 20,000lb. ; and the experiments of Mr. Smeaton give 22,750lb. raiſed one foot high in one minute, as above: perhaps 22,000lb. may be a proper mean for the actual work of a horſe, and is equivalent to 100lb. $2\frac{1}{2}$ miles per hour. See Force.

Horse-*radiſh*, in *Gardening*. See Cochlearia.

Horse-*rake*, in *Agriculture*, a name applied to a large ſort of rake which is uſually drawn by a horſe, and frequently in uſe in the more ſouthern parts of the kingdom. It anſwers well for ſtubbles, and large horſe-rakes for hay are now likewiſe found very beneficial. See Rake.

Horse-*river*, or *Rio de Cavallos*, in *Geography*, a river of Mexico, which runs into the bay of Honduras, N. lat. 15° 48′. W. long. 86° 45′.

Horse-*run*, in *Engineery*, is a ſimple and uſeful modern contrivance, for drawing up loaded wheel-barrows of ſoil from the deep-cuttings of canals, docks, &c. by the help of a horſe which goes backwards and forwards, inſtead of round, as in a horſe-gin, which we have fully deſcribed in our article Canal.

Horse *Stealing*, the taking of horſes from the paſture grounds or other places, by perſons who have no claim or right to them whatever.

It is a practice which is very prevalent, notwithſtanding the very heavy puniſhments and ſevere penalties that are inflicted in caſes of detection. There is much difficulty in providing any full and adequate remedy for this nefarious practice; it has, however, been ſuggeſted as the beſt mode of ſecurity to lock "upon the ſhank or paſtern of the horſe, a caſe hardened, and file proof iron ring, lined with ſome ſoft material to prevent chafing, and bearing the owner's name and place of abode," though "ſome have preferred the fixing a collar upon the neck," but "which is rather more expenſive, and perhaps leſs ſecure from the file," yet "in either caſe the price would not be any great object. It is granted, there would be no abſolute ſecurity in this plan, ſince thieves get their bread by their ingenuity; but it would certainly place a very great and formidable difficulty in the way of the exerciſe of their calling. There are few thieves, but who, on inſpection, would prefer a horſe without this troubleſome mark upon him. Granting a man did his buſineſs at random, and blundered upon a horſe in the dark bearing the aforeſaid mark, as ſoon as the light ſhould enable him to diſcover it, he would, no doubt, run away from his new and dangerous bargain as faſt as he would from a thief-taker. Suppoſe even a man went prepared with tools proper to deſtroy the iron, he muſt have an aſſiſtant, and the operation would require ſome time, which would riſk a diſcovery. In caſes of ſtrays, the ſecurity is complete. But, in all caſes, it ſeems the preſent trouble is ſuppoſed to outweigh the eventual benefit of precaution." But this is left to the attentive calculation of ſuch as are intereſted in the matter. Where the horſes are of the more valuable kinds, no methods of precaution which have any chance of being uſeful ſhould be neglected.

Horse-*tail*, *Shrubby*, in *Gardening*. See Ephedra.

Horse-*tail plant*, *Petrified*, in *Natural Hiſtory*. In that fruitful repoſitory of extraneous foſſils, the cliffs of the upper part of the London clay ſtrata in Sheppy iſland, in the Thames river, the ſtrata of which ſeem to anſwer to thoſe juſt now expoſed by the tunnel and deep-cutting for the new road on the eaſt ſide of Highgate town, Mr. Jacobs deſcribes (Plantæ Faverſhamienſes, p. 138.) joints of the equiſetum or horſe-tail plant, as ſometimes found, of the naked ſpecies, three inches long. Dr. Grew, in his catalogue of "Rarities" of Greſham college, p. 268. mentions a horſe-tail plant or hippurites, a ſtone with the impreſſed figure of three ſtalks, elegantly riſing up from one root, preſerved in that collection.

Horse-*tree*, a common name ſignifying the ſame thing as whippin, whipple, or ſwingle tree, when applied to the draught of tools of different kinds.

Horse, *Wooden*, an inſtrument of military puniſhment, formerly much in uſe in different ſervices. The wooden horſe was formed of planks nailed together, ſo as to form a ſharp ridge or angle about eight or nine feet long, which ridge repreſented the back of a horſe. It was ſupported by four poſts or legs, about ſix or ſeven feet long, placed on a ſtand made moveable by trucks; and in order to complete the reſemblance, a head and tail were added. When a ſoldier or ſoldiers were ſentenced by a court-martial, or ordered by the commanding officer of the corps to ride this horſe, they were placed on the back with their hands tied behind them, and frequently, as an increaſe of the puniſhment, had muſkets tied to their legs, to prevent, as it was jocularly ſaid, their horſe from kicking them off; this puniſhment being chiefly inflicted on the infantry, who were ſuppoſed to be unuſed to ride. At length, riding the wooden horſe having been found to injure the men materially, and ſometimes to rupture them, it was left off.

Horse *Worm*, in *Natural Hiſtory*, a ſpecies of fly-worm called alſo *bott*, produced of eggs depoſited by a two-winged fly, of the ſhape and ſize of the humble-bee, in the inteſtines of horſes. See Botts.

Horses, in *Engineery*, is applied in ſome maritime diſtricts to the jetties or erections of wood or faſcinery, made to protect the ſea walls from the waves.

HORSE-BLOCK. See Anabathra.

HORSE-MAN, the name given to a particular ſpecies of pigeon, called by Moore the *columba tabellaria minor*. It very much reſembles in ſhape the carrier-pigeon, but it is ſmaller, and ſhorter necked; the protuberant fleſh on the beak, and round the eye, is alſo leſs in quantity; it is more barrel-headed alſo, and the eye is ſomewhat pinched. It is a matter of diſpute whether this be an original ſpecies of pigeon, or a baſtard between the carrier and tumbler pigeons.

There are of this ſpecies of all ſorts of feathers, but the blue and blue-pieds are the moſt valued. Theſe are one of the ſort of pigeons made uſe of in England for carrying letters, and flying for wagers; for the true original carriers are now very ſcarce, and not riſked on every trifling occaſion.

HORSEMANSHIP, the art of breaking, diſciplining, and managing horſes.

Horſemanſhip, in its latitude, includes what relates to the knowledge of the make, colour, age, temper, and qualities, of horſes; their reſpective countries and climates, with the manner of breeding, propagating, &c. the diſcovery of the uſes or ſervice they are fitted for; whether the wars, the race, the ſaddle, or labour; and forwarding and accommodating them for this purpoſe.

In this general ſenſe it alſo includes the knowledge of the defects and diſeaſes of horſes, and the remedies proper for the ſame, with the ſeveral operations requiſite thereto, as *docking*, *gelding*, *ſhoeing*, &c. and thus takes in the farrier's province.

But the word is in a more peculiar manner underſtood of the art of riding, or of directing a horſe to advantage; not only in the ordinary motions, but more eſpecially in the managing, or making him work upon volts, airs, &c. See Manege.

HORSHAM, in *Geography*, a market and borough town in the rape of Bramber, and county of Suſſex, England, is traditionally ſaid to derive its name from Horſh, a Saxon chieftain, who is ſuppoſed to have had either a place of reſidence here, or to have achieved ſome victory in this part of the country. There is no record preſerved, however, of either event, and the origin of the place may be as rationally referred to ſome other perſon or circumſtance. In the county of Norfolk is another pariſh of the ſame name, which has equal claims to the ſame etymology. Of the preſent Horſham, we do not find any early records; though it is ſtated to have returned two members to parliament in the reign of king Edward I. This privilege it ſtill retains, as a preſcription borough. Its civil government is veſted in a ſteward, two bailiffs, and two conſtables; whilſt its election franchiſe is confined to 25 burgage holders, *i. e.* perſons occupying, or poſſeſſing burgage houſes, or lands within the borough. Theſe are now wholly the property of the duke of Norfolk; who, conſequently, has the unreſtrained power of nominating and appointing the members. The county gaol, for Suſſex, ſtands near the ſouth-eaſtern extremity of this town. It is a large convenient edifice, and is built conformably to the plan recommended by Howard. From ancient cuſtom, the aſſizes for the county of Suſſex are alternately held here, and at Lewes; at this place, the petty ſeſſions are alſo held. The church, a large irregular building, contains two old tombs, beſides mural tablets of modern date. In the town are four other places of worſhip, belonging to different ſects of diſſenters. Here is a free-ſchool, which was originally endowed with 30*l.* a year for a maſter, and 20*l.* for an uſher. In 1801 the town contained 573 houſes, and 3204 inhabitants. Here is a weekly market on Saturdays, which is noted for its poultry; and the laſt Tueſday of every month is appropriated for a cattle market. Here are four annual fairs. Horſham is 41 miles S. of London, and 20 miles N.W. of Brighton.

In the vicinity of the town are the following ſeats: Hills, lately belonging to lady Irving. Field Place, the ſeat of Timothy Shelley, eſq. New Lodge, the ſeat of I. Aldridge, eſq. Coolhurſt, Edward Carter, eſq. Den Park.

Horsham, a townſhip of America, in Montgomery county, Pennſylvania, containing 781 inhabitants.

Horsham *Stone* is a kind of thin broad ſlate, of a greyiſh colour; formerly much uſed, eſpecially in Suſſex, to heal or cover churches and chancels, great houſes, &c. but on account of its weight very unfit for the purpoſe.

It is called Horſham ſtone, becauſe chiefly brought from the town of Horſham in Suſſex.

HORSEHEAD, in *Mining*, is a large hopper of wood, the ſmall end of which is cloſe joined to the air-pipes, or fangs, which are uſed in the lead mines of Derbyſhire ſubject to foul air: the horſehead being turned towards the wind from time to time, a current of air is by that means directed down the fangs into the mine.

Horsehead *Cockle*, or *Hippocephaloides*, in *Natural Hiſtory*, depreſſed on one ſide and having the ſuture or joint in the middle of the depreſſed part, is found in the limeſtone ſtrata of Buckinghamſhire. Jones's Phyſ. Diſq. p. 404. Sometimes theſe are called horſehead muſcles by the quarrymen and others.

Horsehead *Flints*, in *Geology*, is a name pretty generally known in the chalk diſtricts of England, and adopted by Mr. Smith and his pupils, for the large and irregular black flints with white ſurfaces, reſembling in ſize, and ſomewhat in outward ſhape, the heads or ſkulls of horſes, which being curiouſly locked into each other, almoſt like the ſutures of a ſkull, form a ſtratum of flints of ſix to ten inches thick on the very top of the chalk ſeries, and of which theſe horſehead flints are very characteriſtic. Theſe flints are very commonly found in the alluvial clays of Woburn, in Bedfordſhire, and other places ſtill more diſtant from the chalk; and what among other circumſtances prove theſe clays, &c. to have been moved in maſs and not *rolled* along the ſurface by water, is, that the horſehead flints, though exceedingly brittle, often have large holes through them near their edges, ſo as to form handles to them, which are entire and unbroken, though a ſlight blow would detach them as the handle of an earthen pitcher or mug; by means of theſe holes they are very often ſuſpended as jack-weights, and for other ſimilar purpoſes, in the diſtricts where they are found.

HORSELEY, John, in *Biography*, a learned antiquarian, was a native of Northumberland, and was educated at the grammar ſchool of Newcaſtle-upon-Tyne; he ſtudied for ſome time at one of the northern univerſities, where he took a degree, and then ſettled at Morpeth as paſtor to a congregation of Diſſenters. He died in December 1731, at the age of 46. His great work did not appear till 1732, ſome time after his death. It is entitled "Britannia Romana," and contains a large account of all the veſtiges of the connection of the Romans with this iſland. It conſiſts (1) of an hiſtorical relation of all the Roman tranſactions in Britain; (2) of a collection of all the Roman inſcriptions which have been diſcovered in Britain; (3) of the geography of the iſland, as laid down by Ptolemy, &c. Mr. Horſeley was a conſiderable mathematician, and gave lectures in ſeveral branches of natural philoſophy, both at Newcaſtle and Morpeth. Gen. Biog.

HORSENS, in *Geography*, a ſea-port town of Denmark, ſituated on the Baltic, in Jutland, in the dioceſe of Aarhuus; having a harbour with the water too ſhallow for admitting any veſſels beſides lighters. It is a place of conſiderable trade, with manufactures of flannel and other woollen ſtuffs, and contains two churches; 19 miles S.S.W. of Aarhuus. N. lat. 55° 52′. E. long. 9° 52′.

HORSE-SHOE, in *Fortification*, is a work ſometimes of a round, ſometimes of an oval figure, incloſed with a parapet, raiſed in the ditch of a marſhy place, or in low grounds; ſometimes alſo to cover a gate; or to ſerve as a lodgment for ſoldiers, to prevent ſurprizes, or relieve an over-tedious defence.

Horse-shoe *Head*, a diſeaſe in infants, wherein the ſutures of the ſkull are too open, or too great a vacuity is left between them; ſo that the aperture ſhall not be totally cloſed up, or the cranium in that part not be ſo hard as the reſt for ſome years after.

This openneſs is found to be increaſed upon the child's catching cold. When the diſeaſe continues long, it is reputed a ſign of weakneſs and ſhort life. In this caſe, it is uſual to rub the head now and then with warm rum, or brandy, mixed with the white of an egg, and palm-oil.

Sometimes the diſorder ariſes from a collection of waters in the head, called an hydrocephalus.

Horse-shoe, in *Mining*, is uſed by Mr. Kirwan (Geol. Eſſ. p. 337.), to expreſs a depreſſion of ſtrata in a trough, ſuch, probably, as the vale of the goyte between Derbyſhire and Cheſhire preſents a ſtriking inſtance of, according to Mr. Farey's Report, vol. i. p. 172; in this caſe the edges of the ſtrata preſent the form of a lengthened horſe-ſhoe dipping inwards; but a more remarkable and larger caſe of a horſe-ſhoe, of the edges of ſtrata, dipping outwards, is there deſcribed as preſented by the edges of the firſt or millſtone grit rock, from Little Eaton, near Derby, northward to the Woodlands of Hope, and then again ſouthward near to Dilhorn in Staffordſhire.

Horse-shoe, in *Rural Economy*, the well-known iron cover or defence which is faſtened by means of nails upon the foot of the horſe. It requires much care and attention to ſhoe horſes in a ſafe and proper manner. See Shoeing *of Horſes*.

Horse-shoe *Point*, in *Geography*, the moſt ſoutherly point of land, near the E. end of the iſland of St. Chriſtopher. N. lat. 17° 19'. W. long. 63° 32'.

Horse-shoe *Vetch*, in *Botany*. See Vetch.

HORSING-Block, in *Engineery*, is a ſquare frame of ſtrong boards uſed by canal diggers, to elevate the ends of their wheeling-planks upon. See *Plate* VII. *of* Canals, *fig.* 49.

HORSLEY, Samuel, in *Biography*, eldeſt of the three ſons of the Rev. Mr. Horſley, formerly miniſter of St. Martin's in the Fields, was born about the year 1737. He was educated at Weſtminſter ſchool, whence he was removed to the univerſity of Cambridge. Here he applied himſelf chiefly to the ſtudy of the mathematics, and not content with reading modern authors, he went back to the profoundeſt of the ancients, and made himſelf maſter of their works. When he had taken his degree of M. A. he went to Oxford as private tutor to the earl of Aylesford. He received at this univerſity the degree of doctor of laws, and in 1769 he printed at the Clarendon preſs his edition of Apollonius, a work of great value, but exceedingly abſtruſe. Here he conceived the deſign of publiſhing a complete edition of the works of ſir Iſaac Newton, for which he began to collect the neceſſary materials. On leaving the univerſity, Dr. Horſley came to London, where he was elected a fellow of the Royal Society, of which he was choſen ſecretary in 1773. He continued to ſerve that office with the greateſt credit to himſelf, as well as benefit to the intereſts of ſcience, till the reſignation of the then preſident, ſir John Pringle. Soon after his ſettling in London, he accepted of the office of chaplain to biſhop Lowth, who preſented him to the rectories of St. Mary Newington and Albury, both in the county of Surry, and in the courſe of the year he married Miſs Botham. In 1776 he publiſhed propoſals for his edition of Newton, which appeared in 1779 in five volumes, royal quarto. To this edition is prefixed a dedication to the king, written by the doctor in excellent Latin, which concludes with theſe words, "Te, Pater, tantum Doctrinarum Artiumque omnium Patronum, diu nobis ſoſpitet, tueatur, cuſtodiat. Tibi vero gratum precor ſit Munus, quod reverentiæ et officii cauſâ Tibi dicat, qui in ſubditorum Tuorum fideliſſimorum numero nomen ſuum profiteri geſtit, unus idem ex humillimis." In 1778, when the controverſy was on foot between Drs. Prieſtley, Price, and others, reſpecting materialiſm and philoſophical neceſſity, Dr. Horſley preached a ſermon on Good Friday at St. Paul's cathedral, which he afterwards publiſhed. In this diſcourſe he endeavours to reconcile the doctrine of divine providence with the free agency of man, and combats the neceſſarian hypotheſis with much ability. About this period he was appointed archdeacon of St. Alban's by his patron biſhop Lowth, who, in 1782, preſented him to the valuable living of South Weald, in Eſſex. From this time he entered avowedly and zealouſly into the controverſy of the Unitarian doctrine with Dr. Prieſtley; the latter maintaining the ſimple humanity of Chriſt, in oppoſition to the creed of the eſtabliſhed church, which admits of three Gods in every reſpect equal. The controverſy was carried on with ſome bitterneſs, till at length the archdeacon ſignified his intention to proceed no farther, ſaying, that it was an endleſs taſk to contend upon an exhauſted topic with one who was never diſpoſed to ceaſe diſputing without having the laſt word. In 1789, Dr. Horſley collected the tracts which he had written on the occaſion, and printed them in one volume octavo, with additions, particularly a ſermon on the Incarnation, which had a material relation to the controverſy in queſtion. He had, in the year 1788, been raiſed to the biſhopric of St. David's by the intereſt of lord Thurlow, who ſaid, that thoſe who defended the church and its doctrines were juſtly entitled to the honours and emoluments it had to confer. In the year 1790, when the Proteſtant Diſſenters were ſtruggling for relief from the teſt and corporation acts, the biſhop publiſhed a pamphlet without his name, entitled "A Review of the Caſe of the Proteſtant Diſſenters." This piece excited much attention, its ſtyle was nervous, but it was accuſed of illiberality and unfairneſs in the argument. It was a juſtification of high church principles, and brought forth a number of anſwers from perſons in and out of the church. In the year 1794, biſhop Horſley was tranſlated to the ſee of Rocheſter, which he held with the deanery of Weſtminſter. In 1796 he gave the public a very learned diſſertation on "The Latin and Greek Proſodies," which he dedicated to lord Thurlow; and in the year 1800 appeared in quarto his Critical Diſquiſitions on the Eighteenth Chapter of Iſaiah, in a letter to lord King. Two years after this he publiſhed a new tranſlation of the prophet Hoſea, with notes critical and explanatory. He was in the ſame year tranſlated to the rich ſee of St. Aſaph; after this, the principal work that came from his lordſhip's pen was a critical eſſay "On Virgil's two Seaſons of Honey, and his Seaſon of ſowing Wheat; with a New and Compendious Method of Inveſtigating the Riſings and Settings of the fixed Stars." Dr. Horſley died at Brighton on the 4th of October, 1806. No man of the age, perhaps, poſſeſſed more of what is generally underſtood by the idea of recondite learning. As a ſenator he was conſidered in the firſt claſs; there were few important diſcuſſions in the houſe of peers, eſpecially when the topics referred to the hierarchical eſtabliſhments of the country, to the French revolution, or to the ſlave trade, of which he was a ſyſtematic and eloquent opponent, in which his lordſhip did not participate. As an orator, his voice was deep, full-toned, and commanding, his enunciation diſtinct, and his delivery highly advantageous. As an author, beſides the works already referred to, he publiſhed many ſmaller pieces, and alſo three volumes entitled "Elementary Treatiſes on the Fundamental Principles of Practical Mathematics for the Uſe of Students." As a biſhop, an overſeer of his dioceſe, his conduct was exemplary and very praiſe-worthy. In the ſee of St. David's, which was ſaid to exhibit more of ignorance and poverty than that of any other in the kingdom, he carried through a regular ſyſtem of reform. He regulated the condition of the clergy, and proceeded to a ſtricter courſe with reſpect to the candidates for holy orders, admitting none without perſonally examining them himſelf, and looking very narrowly into the titles which they produced. With all this vigilance, his lordſhip acted to them as a tender father, encouraging them to viſit him during his ſtay in the country, which was uſually for ſeveral months in the year, aſſiſting them with advice, and miniſtering to their temporal neceſſities with a liberal hand. In his progreſs through the dioceſe, he frequently preached in the pariſh churches, and beſtowed conſiderable largeſſes on the poor. "He was," ſays his biographer, "a bleſſing to his people, and they followed him with grateful hearts, and parted from him with infinite reluctance." Since the death of the biſhop, two volumes of his ſermons have been given to the world by his ſon, who propoſes, "if it pleaſe God to ſpare him a few years," to publiſh an uniform edition of all his father's works, with a biographical account of the author. The biſhop has left behind him in MS., but ready for the preſs, a Tranſlation of the Book of Pſalms, with Notes; a Treatiſe on the Pentateuch, and on the Hiſtorical Books of the Old Teſtament; a Treatiſe on the Prophets; containing Notes on Iſaiah, Jeremiah, Ezekiel, Joel, Amos, and Obadiah; which will be publiſhed, if the demand for them be ſuch as to juſtify the undertaking. Monthly Magazine, vol. xxii. Preface to Sermons, by Samuel Horſley, LL.D. F.R.S F.A.S. late lord biſhop of St. Aſaph.

HORST, in *Geography*, a town of Weſtphalia, in the biſhopric of Paderborn; 10 miles W.S.W. of Paderborn.—Alſo, a town of Germany, in the county of Marks; ſix miles N.N.W. of Hattingen.—Alſo, a town of the duchy of Holſtein; four miles E. of Krempe.

HORSTIUS, JAMES, in *Biography*, a phyſician and botaniſt, was born at Torgau, in May 1537, and took the degree of M.D. at Francfort on the Oder in 1562. After having practiſed his profeſſion for ſeveral years, he was appointed ordinary phyſician of the archduke of Auſtria in 1580; a poſt which he occupied about four years, and then was elected to a chair in the univerſity of Helmſtadt, in which he pronounced an inaugural oration, "De remoris diſcentium medicinam, et earum cauſis." He is ſaid to have been dean of the faculty and vice-rector of that univerſity in 1595, and to have died in May 1600; but others believe that his death occurred earlier. His works are as follows: "Precationes Medicorum Piæ," Helmſtadt, 1585, 12mo. "De vite vinifera ejuſque partibus opuſculum," ibid. 1587, 8vo. Marpurg, 1630, with the following: "Herbarium Horſtianum, ſeu, de ſelectis plantis et radicibus libri duo," Helmſt. 1587. "De natura, differentiis, et cauſis eorum qui dormientes ambulant," Lipſiæ, 1593, 8vo. "De aureo dente maxillari pueri Sileſii," Lipſ. 1595. "Epiſtolæ Philoſophicæ et Medicinales," ibid. 1596. "Diſputationes Catholicæ de rebus ſecundum et præter naturam," Wittemburg, 1609. Eloy. Dict. Hiſt.

HORSTIUS, GREGORY, an able and learned phyſician, nephew of the preceding, was born at Torgau, where his father was one of the chief magiſtrates, in the year 1578. After having received the rudiments of his education in the ſchools of Torgau and Halberſtadt, in which he far outſtripped his equals in age, he went to the univerſity of Wittemburg, and commenced the ſtudy of medicine; and afterwards travelled through the principal ſtates of Germany, and into Switzerland, being introduced not only in the ſchools of ſcience, but to men of literature in general. At Baſil he received the degree of M.D. in March 1606; and on his return, in the ſame year, to his native place, he was immediately appointed to a medical profeſſorſhip, in the univerſity of Wittemburg, by the elector of Saxony. Two years afterwards he was promoted by the Landgrave of Heſſe to a medical chair in the college at Gieſſen, and in 1609 was honoured with the title of Archiater of Heſſe. At this time his profeſſional character had riſen in the public eſtimation, and he numbered among his patients the principal nobility of the diſtrict. In 1622, he received a public invitation from the magiſtracy of Ulm to ſettle there as phyſician to that city, and as preſident of the college. He fulfilled his duties in both theſe offices with great reputation; and his integrity and humanity, not leſs than his extenſive erudition, and his ſucceſsful practice, endeared him to his fellow-citizens, and claimed the reſpect and admiration of the ſurrounding ſtates. He died in the month of Auguſt 1636, aged 58 years. During his reſidence at Gieſſen and at Ulm he employed his leiſure in active ſtudy, and he left a conſiderable number of works, of which it will be ſufficient to enumerate the titles of the principal. The whole of his works were collected and publiſhed, under the title of "Opera Medica," in 1660, 3 vols. folio, at Nuremberg, by his youngeſt ſon, Gregory. Among his ſeparate publications are "De Natura Humana Libri duo," Wittemburg, 1607. "Tractatus de Scorbuto, ſive, de magnis Hippocratis Lienibus, Pliniique Stomacace et Scelotyrbe," Gieſſen, 1609, 1615. "Centuria problematum Medicorum," 1610. "De morbis eorumque cauſis Liber," ibid. 1612, in 4to. "De tuenda ſanitate Studioſorum et Literatorum Libri duo," ibid. 1615, in 8vo. "De natura Thermarum Diſſertatio," 1618, in 4to. with ſome other tracts. He publiſhed alſo two volumes in quarto, at Ulm, 1625—28, "Obſervationum Medicarum ſingularium Libri quatuor," with a ſupplement, in 1631; and an abridgment of his uncle's "Herbarium Horſtianum," 1630; and ſome ſmaller tracts, entitled "De natura amoris;" De natura motus animalis et voluntarii;" "De cauſis ſimilitudinis et diſſimilitudinis in fœtu reſpectu parentum," &c. See Gr. Horſtii Oratio funebris à J. D. Dieterich, ſubjoined to his works. Eloy. Dict. Hiſt.

HORSTIUS, JOHN-DANIEL, and GREGORY, two ſons of the preceding, were alſo phyſicians and profeſſors of medicine; the latter of whom died at the age of 35; but John-Daniel lived to his 65th year, and was the author of ſeveral works, chiefly anatomical, and of little value at preſent. He was concerned with his brother Gregory in editing the collection of his father's works; and likewiſe publiſhed an edition of the "Queſtiones Medico-legales" of Paul Zacchias, Francfort, 1666, in folio; and an edition of the "Opera Medica" of Riverius, at the ſame place, in 1674, in folio. Eloy.

HORSTMAR, in *Geography*, a town of Germany, in the biſhopric of Munſter; 15 miles N.W. of Munſter. N. lat. 52° 9'. E. long. 7° 17'.

HORSZCZYK, a town of Poland, in the palatinate of Volhynia; 48 miles N. of Zytomiers.

HORTA, in *Mythology*, a goddeſs among the Romans, who preſided over youth and excited them to virtue by her exhortations. Her temple is never ſhut, to admoniſh youth, ſo liable to be ſeduced, *cerea in vitrum flecti*, that they ſhould be always diſpoſed with particular vigilance over themſelves to the practice of virtue.

HORTAGILERS, in the grand ſeignior's court, are upholſterers, or tapeſtry-hangers.

There is no city better or more orderly regulated than the grand ſeignior's camp; and to have a notion of the magnificence of that prince, he muſt be ſeen in that equipage; as he is much better lodged and accommodated there than at Conſtantinople, or any other city of his dominions.

He has always two tents or pavilions, and two ſets of furniture entire; that, while he is in one, they may pitch or ſpread the other.

In order to this, he has conſtantly 400 hortagilers, or upholſterers in his retinue, who go a day's journey before him to fix on a proper place. They firſt prepare the ſultan's tent, and then thoſe of the officers of the Porte; and the beglerbegs, according to their rank.

HORTATOR, in the *Roman Navigation*, an officer whoſe buſineſs it was to give the word of command to the rowers, and to direct them when to ſtop, and when to ply their oars.

The Greeks gave the name of celeuſtes to this officer.

HORTE, JOHN, in *Biography*, a learned prelate, who was educated for a diſſenting miniſter under Mr. Thomas Rowe, and had for a fellow-pupil the celebrated Dr. Iſaac

Watts, with whom he kept up a correſpondence till the doctor's death. He was ſettled in early life as a diſſenting miniſter at Marſhfield in Gloceſterſhire; while there, he conformed to the church, and in 1708 preached a viſitation ſermon at Ayleſbury. He was afterwards taken to Ireland as chaplain to the lord-lieutenant, where he was made biſhop of Leighlin and Ferns, from whence he was tranſlated to Kilmore, and in 1742 to the archbiſhopric of Tuam. He died in 1751. His works are a volume of excellent ſermons, printed at Dublin in 1738, and afterwards at London in 1757. Month. Mag.

HORTENSIUS, Quintus, a diſtinguiſhed Roman orator, born about the year 115 B.C. He began to plead before he was nineteen years of age, and with ſo much talent, that the great Cicero ſaid of him, "the genius of Hortenſius, like the ſtatue of Phidias, was at once beheld and approved." He afterwards entered the army and roſe to the poſt of military tribune: he then paſſed through the uſual courſe of civil offices to the conſulſhip, which he ſerved with Cæcilius Metellus B. C. 70. At that period he had acquired ſo much power and diſtinction by his eloquence, that when the lot of the Cretan war fell upon him, he reſigned it to his colleague, preferring the diſtinction and celebrity of the forum and ſenate-houſe. He continued to plead till his death, which happened in his ſixty-fourth year, or 51 B. C. We refer to the article Cato for a curious incident in the domeſtic life of Hortenſius. As an orator he was elegantly ſplendid in his diction, apt in his compoſition, and copious in his matter. He embraced the whole ſubject in his memory, divided it acutely, and omitted nothing which the cauſe ſupplied, either for confirmation or refutation. He was aided with uncommon powers of memory, which enabled him to repeat a whole oration in the words which he had previouſly conceived, without committing it to writing, and to go through all the arguments of an opponent in their order. Though Hortenſius died very rich, he lived in a very luxurious ſtyle: he poſſeſſed ſeveral magnificent country ſeats, furniſhed with parks, aviaries, fiſh-ponds, &c. in which he very much delighted. He was accuſtomed with his own hand to irrigate his fine plane-trees with wine, which may render credible the anecdote of his leaving to his heir 10,000 caſks of that liquor. His daughter Hortenſia inherited her father's eloquence, and when the Roman women were required to render on oath an account of their property, preparatory to a heavy tax, ſhe pleaded the cauſe of her ſex with ſuch force, that the decree was annulled. Her harangue, which was delivered on this occaſion, before the triumvirs, Antony, Octavius, and Lepidus, was extant in the time of Quintilian, who ſpeaks of it with applauſe. Univer. Hiſt.

Hortensius, Lambert, a man of letters, was born at Montfort, in the province of Utrecht, in the year 1518. He derived his name from the circumſtance of his father being a gardener. He ſtudied at the univerſity of Louvain, and was afterwards a profeſſor in the college of St. Jerome at Utrecht, and entered into prieſts' orders. In 1544 he was appointed prefect of the college of Naarden, which he held till his death, notwithſtanding other invitations. When the town was ſacked by the Spaniards in 1572, his houſe was pillaged, and he had the cruel misfortune of ſeeing his natural ſon maſſacred before his eyes. He himſelf would have ſhared the ſame fate, had he not been recognized and ſaved by one of his former pupils. He did not long ſurvive this evil, but died in the courſe of a year or two. He was a general ſcholar, and publiſhed many works, chiefly in the Latin language. He tranſlated four of the comedies of Ariſtophanes into Latin verſe, and he wrote annotations on the firſt ſix books of the Æneid, and on Lucan's Pharſalia; the latter he ſo highly prized, that it was the only thing he was ſolicitous to ſave at the pillage of his houſe. They were publiſhed after his death at Utrecht in 1578. His chief work, as an hiſtorian, was entitled "De Bello Germanico, a Carolo V. Cæſ. geſto lib. vii."

Hortensius, Martin, an aſtronomer, was born at Delft in 1605, and died in the flower of his age, in 1639. He is known by a diſſertation "De Mercurio ſub ſole viſo, a Venere inviſa;" alſo two diſcourſes "De utilitate et dignitate Matheſeos, et de Oculo ejuſque Præſtantia."

HORTICULTURE, compounded of *hortus, garden;* and *colo, I till, dreſs,* &c. the art of gardening. See Gardening.

HORTOBAGY, in *Geography,* a town of Hungary, on a river of the ſame name, which runs into the Theyſſe; 17 miles S.S.W. of Nanas.

HORTON, a townſhip of Nova Scotia, in King's county; traverſed by a river, which ſupplies the inhabitants with excellent ſalmon.

HORTULANUS, in *Ornithology,* the name of a ſpecies of the emberiza, in the Linnæan ſyſtem, though ſome writers have made this a diſtinct genus.

HORTUS, a name uſed by ſome authors for the female genital parts of animals.

Hortus *Siccus.* See Herbal and Herbarium.

HORVATZ, in *Geography,* a town of Croatia; 18 miles S.W. of Varaſdin.

HORVOS, an iſland in the gulf of Mexico, 25 miles long and three wide, ſeparated by a narrow channel from the N. coaſt of Yucatan. N. lat. 21° 10'. W. long. 70° 5'.

HORWAL, a town of Lithuania, in the palatinate of Minſk; 28 miles S. of Rohaczow.

HORZITZ, a town of Bohemia, in the circle of Czaſlau; 20 miles S.S.W. of Czaſlau.—Alſo, a town of Bohemia, in the circle of Konigingratz. N. lat. 50° 18'. E. long. 15° 20'.

HOSANCOCK Creek, a river of Pennſylvania, which runs into the Schuylkill. N. lat. 40° 8'. W. long. 75° 30'.

HOSANNA, in the *Hebrew Ceremonies,* a prayer which they rehearſed on the ſeveral days of the feaſt of tabernacles.

It was thus called, becauſe there was frequent repetition therein of the word הושׁיענא, *ſerva nunc,* or *ſerva precor, i. e.* ſave us now; or, ſave us, we pray.

There are divers of theſe hoſannas. The Jews call them *hoſchannoth; i. e.* the hoſannas. Some are rehearſed on the firſt day, others on the ſecond, &c. which they call hoſanna of the firſt day, hoſanna of the ſecond day, &c.

Hosanna *Rabba,* or *Grand Hoſanna,* is a name they give to their feaſt of tabernacles, which laſts eight days; becauſe, during the courſe thereof, they are frequently calling for the aſſiſtance of God, the forgiveneſs of their ſins, and his bleſſing on the new year; and to that purpoſe they make great uſe of the *hoſchannoth,* or prayers above mentioned.

The Jews alſo apply the term hoſanna rabba, in a more peculiar manner, to the ſeventh day of the feaſt of tabernacles; becauſe they apply themſelves more immediately on that day to invoke the divine bleſſing, &c.

HOSANPORAH, in *Geography,* a town of Hindooſtan, in Bahar; 25 miles N.N.W. of Chuprah. N. lat. 26° 4'. E. long. 84° 30'.

HOSE, from the Saxon *hoſa,* a ſtocking. See Stocking.

Hose, a term frequently made uſe of to ſignify the ſheath from which the ſhoot of grain proceeds.

Hose *in Hoſe,* among *Botaniſts,* ſignifies one long huſk of a flower within another; as in the polyanthus. See Primrose.

Hose-*Huſk*, a long round huſk; as in pinks, july-flowers, &c.

HOSEA, in *Scripture Hiſtory*, a canonical book of the Old Teſtament, ſo called from the prophet of that name, its author; the firſt in order of the leſſer prophets, and perhaps, Jonah excepted, the moſt ancient of them all. He lived in the kingdom of Samaria, and delivered his prophecies under the reign of Jeroboam II. and his ſucceſſors, kings of Iſrael; and under the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah. His principal deſign is to publiſh the groſs idolatry of the people of Judah and Iſrael, to denounce the divine vengeance againſt them, and to foretel the captivity in Aſſyria. His ſtyle, ſays biſhop Lowth, exhibits the appearance of very remote antiquity; it is pointed, energetic, and conciſe. It bears a diſtinguiſhed mark of poetical compoſition, in that priſtine brevity and condenſation, which are obſervable in the ſentences, and which later writers have in ſome meaſure neglected. This peculiarity has not eſcaped the obſervation of Jerom. "He is altogether," ſays he, ſpeaking of this prophet, "laconic and ſententious." But this very circumſtance, which was anciently ſuppoſed, without doubt, to impart uncommon force and elegance, in the preſent ruinous ſtate of Hebrew literature, is productive of ſo much obſcurity, that although the general ſubject of this writer be ſufficiently obvious, he is the moſt difficult and perplexed of all the prophets. Beſides, the duration of his miniſtry muſt include a very conſiderable ſpace of time; but we have now only a ſmall volume of his remaining, which, it ſeems, contains his principal prophecies: and theſe are extant in a continued ſeries, with no marks of diſtinction as to the times in which they were publiſhed, or the ſubjects of which they treat. We need not therefore be ſurpriſed, if, in peruſing the prophecies of Hoſea, we ſometimes find ourſelves in a ſimilar predicament with thoſe who conſulted the ſcattered leaves of the Sibyl. Lowth's Lect. on the ſacred poetry of the Hebrews, by Gregory, vol. ii. See Hebrew *Poetry*.

HOSEEPOUR, in *Geography*, a town of Hindooſtan, in Bahar; 50 miles N.W. of Chuprah. N. lat. 26° 25′. E. long. 84° 18′.

HOSHEARPORUM, a town of Hindooſtan, in Lahore; 40 miles E. of Jallindar.

HOSIUS, Stanislaus, *Cardinal*, in *Biography*, one of the moſt illuſtrious Catholic prelates in the 16th century, was a native of Cracow, and born in the year 1504. He received his early education at the place of his birth, and was ſent to purſue his academical ſtudies at the univerſity of Padua. After continuing there ſome time, he removed to Bologna, where he was admitted to the degree of doctor of laws. The ſuperiority of his talents brought him to the notice of the king, who made him his ſecretary, and afterwards employed him in the chancellery, in the management of the moſt important ſtate affairs. Shortly after this he was nominated to the biſhopric of Culm, from whence he was tranſlated to the ſee of Walmia. He was now employed on miſſions of importance by the pope Pius IV. to the emperor Ferdinand, and to the king of Bohemia, to negociate for the continuation of the council of Trent. Having proved ſucceſsful in his negociations, Pius ſent him, in 1561, a cardinal's hat, which he declined, till the pope obliged him to accept it. He was a learned and zealous champion for the Roman church. His works make two volumes folio: they have gone through many impreſſions. He wrote elegantly, and was an able opponent of the Proteſtants. He died in 1579. The beſt edition of his works is that of 1584. Univer. Hiſt.

HOSLUNDIA, in *Botany*, ſo named by Mr. Peter Thonning, in commemoration of Olaus Hoſlund Smith. Theſe two young Danes undertook an expedition to the coaſt of Guinea, in ſearch of natural productions, where unfortunately the latter, a moſt ardent and intelligent botaniſt, from whoſe reſearches much was expected, met with a premature death.—Vahl. Enum. v. 1. 212.—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, tubular, five-toothed, ſtriated. *Cor.* ringent, almoſt twice as long as the calyx; throat compreſſed: upper lip of the limb erect, ovate, gibbous; lower one gaping, trifid, recurved. *Stam.* Filaments four, growing to the tube; the two barren ones very ſhort; anthers kidney-ſhaped. *Piſt.* Germen ſuperior, four-cleft; ſtyle thread-ſhaped, the length of the perfect ſtamens; ſtigma bifid. *Peric.* Berry ſpurious, formed out of the calyx; roundiſh and ſlightly ten-cornered, umbilicated by the teeth of the calyx, hollow within. *Seeds* four, ovate, in the bottom of the calyx.

Eſſ. Ch. Calyx tubular, five-toothed. Corolla ringent, its upper lip concave. Stamens four, two of which are barren. Seeds four, within the pulpy calyx.

1. *H. oppoſita.* Vahl. Enum. n. 1.—"Leaves oppoſite, oblong-ovate."—Native of buſhy places in Guinea. This *ſhrub* is about ſix feet high, having numerous oppoſite *branches* croſſing each other, with a hairy line between the inſertion of the *leaves*; theſe are two inches or more in length, ſerrated towards the end, entire at the baſe, aromatic. *Flowers* white. *Berry* the ſize of a currant, orange-coloured, downy.

2. *H. verticillata.* Vahl. Enum. n. 2.—"Leaves lanceolate, ternate."—Native of Senegal, and firſt diſcovered by M. Dupuis, formerly ſuperintendant of the garden of the Thuilleries.—*Stem* ſhrubby, branched. *Branches* ſquare, ſtriated, ſlightly downy, hoary at the top. *Leaves* an inch and half long, ſerrated, but entire both at the top and baſe, interſperſed with reſinous, bright ſpots, which are diſcernible by the help of a lens. The parts of fructification in this ſpecies are very ſimilar to thoſe of the laſt. *Panicle* terminal. *Bracteas* minute, awl-ſhaped. *Flowers* ſmall, clothed outwardly with whitiſh hairs.

HOSPINIAN, Rodolphus, in *Biography*, a learned Swiſs divine, was born at Altdorf, near Zurich, in 1547. From a very early period he was diſtinguiſhed for excellent talents, which his friends encouraged and cultivated, by giving him a good education. In 1568 he was admitted into the miniſtry, the duties of which he performed with much diligence and aſſiduity at a country church a few miles from Zurich. After this he had the ſuperintendance firſt of the abbey-ſchool at Zurich, and then of the Caroline ſchool. Amidſt the various occupations of his life he was enabled to compoſe ſome valuable works, of which the principal are, "De Templis, *i. e.* de origine, uſu, et abuſu Templorum;" "De monachis:" "De feſtis Judæorum et Ethnicorum:" "Feſta Chriſtianorum:" "Hiſtoria Sacramentaria:" "Hiſtoria Jeſuitica." He was nearly a year deprived of his ſight, notwithſtanding which he continued to preach as uſual, and in 1613 he ſubmitted to the operation of couching, which ſucceeded to his wiſhes. In 1623 his faculties became ſo much impaired, that he was reduced to a ſecond childhood, in which he continued till his death in 1626. His works, which are enumerated by Bayle, were collected and printed in ſeven volumes folio.

HOSPIDALETTO, in *Geography*, a town of the biſhopric of Trent; 35 miles N.W. of Trent.

HOSPITA, in *Mythology*, a ſurname of Venus, under which appellation ſhe was worſhipped, and had a temple at Memphis, in Egypt.

HOSPITAL, Michael de l', in *Biography*, chancellor of France, was born at Auvergne in 1505. He was educated for the law in the moſt celebrated univerſities of France and Italy, and at the ſame time he greatly diſtinguiſhed himſelf by his proficiency in polite literature. He was in early life made one of the auditors of the rota at Rome, the duties of which he quitted, to follow the law court at Paris. Here he paſſed through various high offices, continually riſing in eſteem for his ability and integrity. In 1560, he was elevated to the dignity of chancellor of France. At this period the kingdom was divided between the factions of contending intereſts. L'Hoſpital was a true patriot, and preferred the honour of the crown and country, to that of any intereſt ſupported by the great. To carry his point he was ſometimes obliged to give way, and even to conſent to a ſevere edict againſt the Proteſtants; this he did with much regret, and he never ceaſed to advocate the cauſe of toleration. In 1562, he was the champion of the decree which allowed freedom of worſhip to the Proteſtants. He was more than once accuſed of being himſelf a Proteſtant, and was excluded from thoſe councils in which the bloody maſſacre was planned. The papal legate would gladly have removed him from office, which he was unable to do, till at length the whole influence of the court was bent on exterminating by violence the reformed religion. He now reſigned his ſeals, and retired into the country to ſpend the remainder of his days, with his books and his friends, and in this retreat he declared that he enjoyed more happineſs than he had ever done in public life. The felicity of privacy was cruelly interrupted by the deteſtable maſſacre of St. Bartholomew in 1572. It was imagined that he might, on account of his great integrity, be included among the number of victims, and when a troop of horſe approached his houſe, he was aſked if he would defend himſelf with fire-arms; "By no means," ſaid he, "and if the wicket is not wide enough to admit the aſſaſſins, ſet open the great gates." The men, who were ſent on the bloody errand, were overtaken by a meſſage from the king, announcing that l'Hoſpital was not among the proſcribed, and was told that the authors of the deed had pardoned him his conſtant oppoſition to their plans; "I did not indeed know," ſaid the excellent man, "that I had merited either death or pardon." He ſurvived this ſhock but a ſhort time, dying in the year 1573, in the ſixty-eighth year of his age. He was author of "Latin poems," which have gone through many editions, and which are grave, but eaſy and energetic; alſo of "Harangues before the States of Orleans;" "Memoirs containing treaties of Peace, &c.;" "A Diſcourſe in favour of Peace," and other tracts. His eulogy, in better times, was made a prize ſubject by the French academy in 1777, and his ſtatue was erected in marble by Lewis XVI., but his noble and manly conduct has erected to his memory a ſtatue more durable than marble. "No one," ſays his biographer, "was more determined in reſiſtance to injuſtice, and if ever he acceded to meaſures which he diſapproved, it was only to prevent worſe." Bayle. Moreri.

Hospital, William-Francis-Anthony, marquis de St. Merne, a celebrated mathematician, of the ſame family as the preceding, was born in 1661. His genius for mathematical purſuits diſcovered itſelf at a very early period; for, being preſent one day at the duke de Rohan's, where ſome able geometricians were ſpeaking of a problem of M. Paſcal's, which appeared very difficult, he ventured to ſay that he believed he could ſolve it. They ſmiled at the aſſertion, and probably regarded the ſuppoſed forwardneſs of a youth of fifteen with contempt; however, in a few days, he ſent them a very neat ſolution, which gave them a very different idea of his talents. He entered the army, and roſe to the poſt of captain of horſe, but ſtill retained his paſſion for mathematics, which he ſtudied at the hours of leiſure from military duty, though he was forced to do it in concealment, as an attachment to the ſciences was thought unbecoming the dignity of a ſoldier. Diſguſted with this idea he quitted the army, and devoted his whole time to ſtudy. When he was little more than thirty years of age, he diſtinguiſhed himſelf by the ſolution of problems drawn from the ſublimeſt geometry, which had been propoſed to the mathematical world by John Bernouilli. In the year 1693 he was admitted an honourary member of the Academy of Sciences at Paris, and from this period the philoſophical tranſactions of France, and thoſe of other countries, were enriched by his papers. He publiſhed a work on ſir Iſaac Newton's fluxions, entitled "Analyſe des infinimens petits," being the firſt Frenchman that ever wrote on this ſubject. He died at the age of 43, in the year 1704, and after his death was publiſhed another mathematical work which he had left in a finiſhed ſtate, and which included "Les Sections Coniques, les Lieux Geometriques, la Conſtruction des Equations, et une Theorie des Courbes Mechaniques."

Hospital, popularly *Spital*, a place or building erected, endowed, or ſupported by charitable contributions, for the reception and relief of the poor, aged, infirm, ſick, and otherwiſe helpleſs.

The word is formed of the Latin *hoſpes, hoſt* or *ſtranger*. In the firſt ages of the church, the biſhop had immediate charge of all the poor, both ſound and diſeaſed; alſo of widows, orphans, ſtrangers, &c. When the churches came to have fixed revenues allotted them, it was decreed, that, at leaſt, one-fourth part thereof ſhould go to the relief of the poor; and to provide for them the more commodiouſly, divers houſes of charity were built, which are ſince denominated hoſpitals.

They were governed wholly by the prieſts and deacons, under the inſpection of the biſhop.

In courſe of time, ſeparate revenues were aſſigned for the hoſpitals; and particular perſons, out of motives of piety and charity, gave lands and money for erecting of hoſpitals.

When the church-diſcipline began to relax, the prieſts, who, till then, had been the adminiſtrators of hoſpitals, converted them into a ſort of benefices, which they held at pleaſure, without giving an account thereof to any body, reſerving the greateſt part of the income to their own uſe; ſo that the intentions of the founders were fruſtrated. To remove this abuſe, the council of Vienne expreſsly prohibited the giving any hoſpital to ſecular prieſts in the way of benefice; and directed the adminiſtration thereof to be given to ſufficient and reſponſible laymen, who ſhould take an oath, like that of tutors, for the faithful diſcharge thereof; and be accountable to the ordinaries. This decree was executed, and confirmed by the council of Trent.

In England, hoſpitals, founded for the mere relief of the indigent and neceſſitous, are peculiarly called *alms-houſes;* the name hoſpital being reſerved to thoſe deſtined for the ſick, aged, young, &c. See Corporation.

Any perſon ſeiſed of an eſtate in fee ſimple, may, by deed inrolled in chancery, erect and found an hoſpital for the ſuſtenance and relief of the poor, to continue for ever; and place ſuch heads, &c. therein as he ſhall think fit; and ſuch hoſpital ſhall be incorporated, and ſubject to ſuch viſitors, &c. as the founder ſhall nominate. Alſo ſuch corporations ſhall have power to take and purchaſe lands not exceeding two hundred pounds per annum, ſo as the ſame be not holden of the king, &c. and to make leaſes for twenty-one years, reſerving the accuſtomed yearly rent; but no hoſpital is to be erected, unleſs upon the foundation it be endowed with lands or hereditaments of the clear yearly value of ten pounds per annum. Stat. 39 Eliz. cap. 5.

This act was made perpetual by the 21 Jac. cap. 1. It is underſtood, in conſequence of this ſtatute, that if the lands given to an hoſpital be afterwards improved, they ſhall be enjoyed by the hoſpital, though they ſhould be above the yearly value of two hundred pounds. And goods and chattels, real or perſonal, may be taken of what value ſoever. (2 Inſt. 722.) But by 9 Geo. II. cap. 39. no lands nor money ſhall be conveyed or ſettled in truſt, for the benefit of any charitable foundations, unleſs the appointment of lands, money, or perſonal eſtate, ſtocks in the public funds excepted, be made by deed indented, ſealed, and delivered in the preſence of two witneſſes, at leaſt twelve calendar months before the death of the donor, and be inrolled in chancery within ſix calendar months next after the execution thereof; and unleſs ſuch ſtock in the public funds be transferred in the public books uſually kept for the transfer of ſtocks, at leaſt ſix calendar months before the death of the donor, and take effect immediately and without the power of revocation. By 43 Eliz. cap. 4. the lord chancellor may iſſue commiſſions to take account of miſapplication of lands and goods, given to hoſpitals, which have no ſpecial viſitors or governors. By 31 Eliz. cap. 6. the place of any perſon, taking reward for nominating to an hoſpital, ſhall be void. By the aforeſaid ſtat. of the 39 Eliz. cap. 5. it is provided, that all leaſes of eſtates for a term exceeding the number of twenty-one years, in poſſeſſion, and on which the accuſtomable yearly rent or more, by the greater part of twenty-one years next before the taking of ſuch leaſe ſhall not be reſerved and yearly payable, ſhall be void. By 43 Eliz. cap. 2. all lands within the pariſh are to be aſſeſſed to the poor's rate, and it has been determined by courts of law, particularly by Holt, in 1 Anne, that hoſpital lands are chargeable to the poor as well as others. (2 Salk. 527.) In the caſe of St. Luke's hoſpital, by 1 Geo. III. it was determined in general, that no hoſpital is chargeable to the pariſh rates, with reſpect to the ſcite thereof, except thoſe parts of it which are inhabited by the officers, whoſe apartments are to be rated as ſingle tenements, of which the ſaid officers are the occupiers. By the annual acts for the land-tax, it is provided, that the ſame ſhall not extend to charge any hoſpital, for or in reſpect to the ſcite of ſuch hoſpital, or any of the buildings within the walls or limits thereof; or to charge any of the houſes or lands, which on or before Mar. 25, 1693, did belong to Chriſt's hoſpital, St. Bartholomew, Bridewell, St. Thomas, and Bethlehem hoſpital; or to charge any other hoſpitals or alms-houſes for or in reſpect of any rents or revenues, which, on or before March 25, 1693, were payable to the ſaid hoſpitals or alms-houſes, for the immediate relief of the poor. But all ſuch lands &c. belonging to any hoſpital or alms-houſe, or ſettled to any charitable or pious uſe, as were aſſeſſed in the fourth year of W. and M. ſhall be liable to be charged. The principal Engliſh hoſpitals are the following:

Hospital, *Aſke's* or *Haberdaſhers*, is an hoſpital ſituated at Hoxton, and erected in 1692, by the company of Haberdaſhers, in purſuance of the will of Robert Aſke, eſq. who left for building and endowing it 30,000*l.* This hoſpital is eſtabliſhed for the maintenance of twenty poor haberdaſhers, and the ſupport and education of twenty boys. Each of the penſioners in this hoſpital has convenient apartments, is provided with proper diet and firing, three pounds yearly in money, and a gown every ſecond year. There are alſo eſtabliſhed ſalaries, &c. for chaplain, clerk, butler, porter, and other domeſtics.

Hospital, *St. Bartholomew's*, is ſituated on the ſouth-eaſt ſide of Smithfield, and incorporated in the laſt year of the reign of Henry VIII. by the name of the hoſpital of the mayor, commonalty, and citizens of London, governors for the poor, called Little St. Bartholomew's, near Weſt-Smithfield. This hoſpital formerly belonged to the priory of St. Bartholomew, in Smithfield, founded by one Rahere, about the year 1102.

At the diſſolution of the monaſteries, Henry VIII. left five hundred marks a-year to it, on condition that the city ſhould add five hundred marks per annum for the relief of ſick and poor people; but it was more largely endowed, for the uſe of ſick and lame perſons only, by Edward VI. by the munificence of the city and private benefactors. This hoſpital, having eſcaped the dreadful fire in 1666, was repaired and beautified by the governors in the year 1691. But the buildings became by length of time ſo ruinous and dangerous, that a ſubſcription was entered into in 1729, for defraying the expence of rebuilding it, on a plan comprehending four detached piles of building to be joined by ſtone gate-ways, about a court or area. Four piles have been erected and finiſhed; one of theſe piles contains a large hall for the reſort of the governors at general courts, a compting-houſe for the committees, and other neceſſary offices; the other three piles contain wards for the reception of the patients, &c.

It is governed by a preſident, treaſurer, &c. It is furniſhed with three phyſicians, and three maſter ſurgeons, beſides as many aſſiſtant ſurgeons, an apothecary, and vicar. The officers of this hoſpital, are a cook, ſteward, renter, matron, and porter. This hoſpital, ſince its enlargement, is capable of accommodating four hundred and twenty patients. It extends relief alſo to a great number of out-patients. By the report of 1811, it appears that this hoſpital adminiſtered relief to 9746 patients in the courſe of the preceding year.

Hospital, *Bethlehem*, or *Bedlam*, was originally a priory, founded by Simon Fitzmary, ſheriff of London, in the year 1247, the 31ſt of Henry III.; but in the year 1547, king Henry VIII. gave this hoſpital to the city, who employed it for the accommodation of lunatics. The preſent ſtately fabric was erected in the city of London in the year 1676, at a charge of about ſeventeen thouſand pounds. It was in length five hundred and forty feet, and forty feet broad, and contained a great number of cells, or rooms for the accommodation of the unfortunate, who are maintained without any expence to their friends; except an allowance for bedding. At each end of this ſtately edifice were erected, in 1733, by the charitable contributions of the citizens, two wings, or ſpacious buildings, for the reception of poor incurable lunatics. But it became neceſſary very lately to take down the eaſt wing, on account of its decay. The report of the number of incurables was, a ſhort time ſince, 82, being 37 men, and 45 women; who, by an order of court in July 1807, pay each 7*s.* per week if ſent by pariſhes, but if ſent by friends, 5*s.* The number of patients capable of relief amount upon an average to 170; and it has been found, at a mean computation, that nearly two out of three are reſtored to mental ſanity. Before this magnificent ſtructure there was a pleaſant garden, incloſed by a ſtately wall about ſeven hundred feet in length. This hoſpital, being united by the charter of Edward VI. to that of Bridewell, has the ſame preſident, governors, who conſiſt of members of the corporation, and of others, who are made governors by benefactions of 50*l.* each, treaſurer, clerk, auditor, phyſician, ſurgeon, and apothecary; but each hoſpital has a ſteward, and inferior officers peculiar to itſelf. The management is entruſted to a committee of 42 governors, ſeven of whom, with the treaſurer, phyſician, and other officers, attend every Saturday in monthly rotation for the admiſſion of patients, and other concerns of the hoſpital. The income of this hoſpital, appropriated to curables and incurables, and ariſing from rents, &c. and dividends on government ſecurities, amounts to 7412*l.* 16*s.* 10*d.* The number of patients in this hoſpital, on the 31ſt of December 1807, was 126, and of thoſe admitted during the year 1808, was 85, the total 211; the number of thoſe cured and diſcharged 52, of buried 12, and of patients in the hoſpital December 31ſt, 1808, 147. By the report of 1811, the number of cured and diſcharged in the preceding year was 81, of buried 7, and of patients remaining 147.

The decay of the buildings of this hoſpital has made it neceſſary to rebuild it; and the committee, upon mature deliberation, have determined to remove it to another ſituation. Accordingly, as the leaſes of the Bridge-houſe eſtates in St. George's fields and Lambeth-marſh fell in at Lady-day 1810, the corporation have agreed with the commiſſioners of thoſe eſtates for a ground plot of nearly twelve acres, fronting the road leading from Newington to Weſtminſter-bridge, part of which was formerly the ſcite of the houſe and gardens called the Dog and Duck; and on this ſpot it is propoſed to erect a new edifice, capable of accommodating a greater number of patients than the preſent building can contain, and ſuitable to the munificence of the city of London. The ſtatues of the two lunatics upon the pillars of the front gates of Old Bethlehem, which have been very much admired as monuments of art, were the work of Caius Gabriel Cibber, a native of Holſtein, who came into England at ſome period previous to the reſtoration of Charles II. to follow his profeſſion as a ſtatuary.

Hospital, *Bridewell,* is ſituated in Bridge-ſtreet, Blackfriars, on a ſpot near the ancient river Fleet, where ſtood the palace in which king John held his court, and within the walls of which was a well dedicated to St. Bridged, or Bride, whence the palace, &c. derived its appellation. This palace had been variouſly occupied; it was the reſidence of cardinal Wolſey during his proſperity, and after his fall of Henry VIII. particularly in 1529. After this time it was ſuffered to decay, and biſhop Ridley begged it of Edward VI., to be converted to ſome charitable uſe. The citizens of London addreſſed the king's council in 1552; and Edward VI., in the ſame year, by a deed between himſelf and the mayor, commonalty, and citizens of London, granted to them all the manor-houſe and pariſh of Bridewell, with the appurtenances in the pariſh of St. Bridget, Fleet-ſtreet, with other lands, and licence to purchaſe four thouſand mark lands, beſides the lands given them by his majeſty in London and elſewhere, and to purchaſe ſo much land, and that the lands ſo given them ſhould be diſcharged of all tenths and firſt-fruits. And out of the ſuppreſſed hoſpital of the Savoy, he gave a great part (whoſe revenue was 700 mark land), beſides bedding and furniture for the maintenance and employment of vagrants and idle perſons, and of poor boys; uniting it with Bethlem hoſpital. The king was ſo deſirous that this grant ſhould be carried into effect, that he directed by his will that it ſhould be performed, and died ſoon after, on July 6, 1553. In 1557 the citizens of London preſcribed certain rules for the government of this hoſpital, and for the power of its governors and officers. (See Bridewell.) By an act paſſed in 1782, the union of Bridewell and Bethlem was recognized, and the preſent method of appointing corporation governors was eſtabliſhed or confirmed. The revenues of Bridewell hoſpital, at that time, May 1792, amounted to 4505*l.* 13*s.* 1*d.* and of Bethlem hoſpital, to 7881*l.* 19*s.* 10*d.*, of which 2284*l.* 17*s.* belonged to the fund for incurables.

The front of this building, ſituated on the weſt ſide of Bridge-ſtreet, Blackfriars, has not for many years exhibited any part of the original palace. At preſent there is one vaſt quadrangle. The chapel is a plain edifice; the priſon's gloomy front occupies the ſouth-weſt corner; and the hall the greater part of the ſouth ſide. The cieling of this large room, thirty-nine paces in length and fifteen in breadth, is horizontal, without any other ornament beſides two flowers, where the luſtres are ſuſpended. At the weſt end, and over the chimney, is a large picture by Holbein, repreſenting Edward VI. in the act of delivering the charter for this hoſpital to the mayor and citizens of London. There are ſome other pictures which we have not room to particularize. It appears (ſee Bridewell), that this inſtitution is of a mixed nature, partaking of the hoſpital, the ſchool of induſtry, the work-houſe, and the priſon for correction. The ſchool is conducted by ſix maſters of different arts, who are elected by the governors, *viz.* a printer, book-binder, ferrit, orris, and galloon weavers, and a ſilver-ſmith, to whom twenty-eight youths are bound from Chriſt's hoſpital, as apprentices, who are clothed at the charge of Bridewell hoſpital, but maintained by their maſters, who receive the whole profit of their work. They were formerly habited in a blue jacket and trowſers, with a white hat; but this ſingularity has been of late judiciouſly aboliſhed in favour of the common clothing of other perſons: when they have ſerved their apprenticeſhip of ſeven years, they receive their freedom, and a gift of ten pounds towards eſtabliſhing themſelves in buſineſs. The workhouſe, and the priſon for vagrants, idle and diſorderly perſons of both ſexes, are ſeparated into ſolitary rooms, where employments are provided, which it is a part of their puniſhment to execute, and which are exerciſed by their taſk-maſters, and ſometimes accompanied with coercion. Although Bethlem and Bridewell hoſpitals are united, and they are governed by the ſame members, diſtinct accounts of their reſpective revenues are kept. The accounts exhibited at Chriſtmas 1808, ſtated a net income of 6201*l.* 6*s.* 11*d.*, ariſing from net rents of the eſtates and the dividends on 3000*l.* 3 per cents., to which legacies and donations are to be ſubjoined. The expences attending the arts-maſters and apprentices amounted to 645*l.* 4*s.* 6*d.*; the charges attending the vagrants to 706*l.* 19*s.*, and the ſalaries and gratuities to the ſeveral officers and ſervants, &c. amounted to 1586*l.* 14*s.* 2*d.*, making a total of 2938*l.* 17*s.* 8*d.*, which exceeded the receipt by 3262*l.* 7*s.* 3*d.* The qualification of a governor is a donation of 50*l.* paid upon election, which is in the general court. This hoſpital is under the immediate management of a preſident, treaſurer, chaplain, phyſician, clerk, ſteward, and other inferior officers. The number of perſons received into this hoſpital, during the year 1809, amounted to 1261, including 279 vagrants or diſorderly perſons, committed by the lord mayor and aldermen, and ordered for hard labour or correction, 917 perſons to be forwarded to their reſpective pariſhes, and 35 apprentices.

Hospital, *Charter-Houſe,* or *Sutton's.* See Chartreuse.

Hospital, *Chriſt's,* popularly called the *Blue-coat Hoſpital,* was anciently a monaſtery of Grey friars, founded by Rahere, the firſt prior thereof in the time of Henry I., or, as others ſay, by John Ewin, citizen and mercer. It was diſſolved by Henry VIII. and granted by him to the city in 1547, and the grant to the citizens was confirmed in 1552, by charter of Edward VI., who converted it into an hoſpital for poor children; who are ſupplied with all neceſſaries and conveniences, cloathed, dieted, and taught.

Since its firſt endowment, it has received abundance of new donations. Beſides the numerous benefactions of private perſons, the city allows this houſe the benefit of ſuperintending and licenſing the carts of London; and a duty of about ¾ths upon every cloth brought to Blackwell-hall, where clerks are kept to receive it. The citizens, by king Edward's charter, are incorporated governors of his ſeveral foundations in the city and liberties of London by the name of the mayor, commonalty, and citizens of the city of London, governors of the poſſeſſions, revenues, and goods of the hoſpitals of Edward VI., &c. A great part of it was burnt down by the great fire in 1666; but is again rebuilt by the care of the governors; though not without incurring a great debt, and anticipating the revenues of the hoſpital; all which incumbrances have been long ſince diſcharged.

Formerly, a thouſand poor children, moſt of them orphans, were maintained on this foundation; eight or nine ſcore yearly put out apprentices, and the girls to ſervice; but the number has fluctuated from various cauſes.

Beſides the children that are maintained within the walls of this hoſpital, there is a conſiderable number of the leaſt and youngeſt provided for in the country, *viz.* at Hertford, in Hertfordſhire, where there are a ſchool-houſe, a maſter's houſe, and ſeveral houſes for nurſes employed in taking care of the children. The number of children under the care and charge of this hoſpital, in 1810-11, was one thouſand two hundred and thirty-two; one hundred and ſeventy-two were put out apprentices, and eight buried.

Here were two mathematical ſchools; the firſt founded by king Charles II. Aug. 19th, 1674, but they are now united. Youths are there taught ſeveral parts of practical mathematics, particularly navigation, to fit them for apprentices to maſters of ſhips; there is alſo a grammar-ſchool (whence the moſt improved boys are yearly ſent to the univerſity), a writing-ſchool, and a ſchool for the girls, where they learn to read, to ſew, and to mark.

In the mathematical ſchool, called the new royal foundation of king Charles II., forty boys are qualified for the ſea; who wear appropriate badges, and whoſe claſſes are examined by the elder brethren of the Trinity-houſe, ten of whom are yearly appointed to ſhip-maſters, and ten others received into their places, who have attained a competency in writing and Latin; and the governors appoint forty more. All the other ſcholars are bound apprentices at fourteen or fifteen years of age for ſeven years; or, if properly qualified, are ſent to either univerſity of Oxford or Cambridge, where they are maintained for a like term: one ſcholar is ſent every year, except on the return of every ſeventh year, when two ſcholars are ſent; the ſcholars have their choice of the college to which they are to go, but Pembroke-hall, in Cambridge, is generally preferred, as moſt advantageous to them; and one ſcholar is alſo ſent to Oxford in eight years. The allowance paid to each of them during the firſt ſeven years is 60*l.* per annum. On St. Matthew's day, 21ſt of September, yearly, the lord mayor in ſtate, with the preſident, aldermen, ſheriffs, treaſurer, and governors, and other company, aſſemble in the great hall after divine ſervice at Chriſt's church, to hear orations from the elder ſcholars; one of whom ſpeaks in Latin, and the other in Engliſh, the latter of theſe having ſpoken in Latin in the preceding year, is now elected off to college, and leaves the ſchool in about a month afterwards: on this occaſion a glove is handed about among the audience for their contribution.

The maſters of theſe ſchools are, a grammar maſter, who is aſſiſted by an under maſter, a mathematical maſter, and two writing maſters, who have 100*l.* per annum each, for their ſalaries, beſides houſes. There are alſo two ſchoolmiſtreſſes. The grammar maſter hath an addition of 20*l.* yearly for cathechiſing the boys, and his uſher is allowed 50*l.* a year. There are likewiſe a drawing maſter and muſic maſter.

The children are admitted by an order of committee and treaſurer, ſigned by the chief clerk. Their education conſiſts of arithmetic, writing, reading, navigation, Latin, and Greek. Their dreſs is the ſame as that uſed in the time of Edward VI., being a blue cloth coat or tunic, reaching to the feet, with yellow breeches and ſtockings, and a round bonnet or cap too ſmall to cover the head, and it is therefore generally taken in the hand. An examination of the children in the grammar ſchool takes place in the months of March and September by an experienced perſon, appointed by the governors. The upper maſter examines the under maſter's higheſt form twice in the year, and takes ſuch as he judges ready for his inſtruction. The holidays allowed are eleven days at Eaſter, including Sundays; one week at Whitſuntide; and at Bartholomew-tide three weeks; and at Chriſtmas 15 days, and the uſual Saint's days, &c. The catechiſer teaches the children the fundamental points of religion three times in each week, and at other times viſits the wards for the inſtruction of the inmates. The Engliſh reading-maſter is authorized to aſſemble all the children belonging to any two wards in the grammar ſchool, from 11 to 12, three times in a week, in order to obtain a knowledge of their progreſs. Thus every child in the 12 wards is examined once in 14 days. He may ſubſtitute for this purpoſe under his own obſervation any boy intended for the univerſity, and he appoints a marker in the ſeveral wards, who is to obſerve and correct miſtakes in the reading of prayers, &c. and he reads himſelf occaſionally for example. If the marker's diligence is approved, he receives a ſilver medal of the founder. The two writing maſters have two uſhers. An exhibition of drawing and ſpecimens of writing takes place in the hall the 31ſt of March and 30th of September; and the writing is ſaid to be of ſuch ſuperlative excellence, that the worſt would procure the writer a ſituation in the moſt faſtidious merchant's counting-houſe.

Among the peculiarities of Chriſt's hoſpital, a ſight is exhibited from Chriſtmas to Eaſter every year, which no other inſtitution, lay, civil, eccleſiaſtical, or eleemoſynary, has ever equalled in their grand ceremonies, or which is more calculated to impreſs the heart of a ſpectator with the livelieſt ſentiments of ſympathetic pleaſure; we mean the ſupper of all the children on Sunday evenings at ſix o'clock, to which ſtrangers are admitted by tickets.

The great hall, which was rebuilt after the fire of London, contains ſeveral tables, which are covered with table-cloths, wooden platters, and buckets of beer, with bread and cheeſe. The treaſurer and governors take their ſeats at the upper end, at a ſemi-circular table; the boys, attended by the nurſes of their ſeveral wards, enter in order, and arrange themſelves on each ſide of the hall; ſtrangers are then admitted, who go along the centre of the hall to the upper end; the maſters of the ſchool, the ſteward, and the matron, take their places there alſo; and the nurſes preſide at each table, on which a great number of candles are placed, and theſe, with many lamps and a large luſtre, illuminate the room. The ceremony then commences by the ſteward ſtriking upon one of the tables three ſtrokes with a mallet, which produces a profound ſilence; one of the boys intended for the church, having aſcended a pulpit on one ſide of the hall, then reads the ſecond leſſon for the afternoon ſervice of the day, and an evening prayer compoſed for the occaſion, at the cloſe of which the reſponſe of "Amen," from about eight hundred youthful voices, has a very intereſting effect; a pſalm or hymn is next ſung by the whole aſſembly, accompanied by the organ: the ſame youth then delivers the grace, after which the boys take their ſeats, and the ſupper proceeds. When the repaſt is concluded, the ſteward again ſtrikes the table as before, and the boys inſtantly arrange themſelves again on each ſide of the hall, and a grace is ſaid from the pulpit: an anthem is then ſung, after which the boys collect all the fragments into ſmall baſkets; and each ward, preceded by its nurſe with lighted candles, marches in order paſt the upper table, where they bow to the governors, and file off to an adjoining ſchool-room, the doors of which are thrown open to receive them, and the ceremony is cloſed.

There is no perſon who has ever witneſſed this ceremony that does not feel the ſublimeſt and the tendereſt emotions: it is a combined offering of the gratitude of hundreds to the throne of Divine Mercy!

The officers of this hoſpital are, a preſident, treaſurer, phyſician, chief-clerk, under clerk and receiver, ſurgeon, apothecary, wardrobe-keeeper, and aſſiſtant clerk, ſteward, matron, &c. The number of governors, ſome of whom ſuperintend this hoſpital, in their ſeveral appropriate departments, is very conſiderable; and it muſt be allowed that no inſtitution of ſuch magnitude is, upon the whole, better conducted: though ſome have thought that the diet, which is plain and ſimple, might admit of uſeful alterations, particularly with regard to vegetables, &c., without any material addition of expence. The qualifications of governors are 200*l.* and a preſent of 200*l.* more, which is expected upon election. This inſtitution is ſupported by the revenues of its eſtabliſhments and funds, and alſo by legacies and benefactions.

HOSPITAL, *Emanuel*, is ſituated in Tothill-fields, in Weſtminſter, and was founded by lady Dacres in 1601, for 20 aged ſingle men and women, each of whom have an allowance of 10*l.* per annum, with the liberty of bringing up a poor child. The city of London has this charity in truſt, with 200*l.* a-year for its ſupport, iſſuing from a leaſe of 199 years, at the expiration of which, the whole manor of Brainſburton, in the county of York, amounting to above 600*l.* per annum, is deviſed for the augmentation of this foundation. In 1735 the court of lord mayor and aldermen erected a ſchool-houſe and dormitory adjoining to this hoſpital, for the reception of twenty poor boys and girls, to be elected out of the pariſhes of St. Margaret, Weſtminſter, and of Chelſea and Hayes in Middleſex, to which the pariſh of St. John, Weſtminſter, has ſince been added, by the court of aldermen, none of the children being admiſſible under ſeven years of age, nor to be maintained there after 14, who are ſupplied with all the neceſſaries of life; the boys are taught to read, write, and accompt, and the girls to read, write, and do plain-work.

In conſequence of the increaſed value of the lands appropriated to the ſupport of this inſtitution, the governors obtained an act of parliament in 1795 for augmenting the number of objects of this charity: and after obtaining this act, five men and five women were admitted as out-penſioners, with ſuch allowance as the court ſhould think fit. And alſo beſides the 20 children in the hoſpital, eight other poor boys are clothed and educated at the hoſpital's expence, their ages being at the time of election from ſeven to ten. The number of girls in the hoſpital has been increaſed from 10 to 12. In conſequence of this act the 10 out-penſioners are allowed 10*l.* per annum, till houſes in the hoſpital become vacant, when they are admitted, and other out-penſioners appointed in their room.

A ſchool was opened at Brainſburton, to which eight poor boys were ſent, and there clothed, maintained, and educated at an eaſy expence, compared with that of the hoſpital in town. In the year 1802 the court of aldermen iſſued new ordinances and regulations, ſimilar to thoſe of the year 1795. The ſalaries and allowances to the maſter and miſtreſſes, and to the warden and ſteward, matron, and poor men and women in the hoſpital, and alſo to the out-penſioners, were ſettled during the pleaſure of the court, and have ſince been increaſed; and the court undertook to pay all the bills of expenditure. The charges are as follows:

	£
The maſter, with the houſe and garden free of taxes, The miſtreſs, do. - - - - - -	110
The poor men and women, in-penſioners with a chaldron of coals, - - - - - -	18
The poor men and women, out-penſioners, - -	10
The warden and ſteward, in addition to the 18*l.* as in-penſioners, - - - - - -	10
The matron, do. - - - - - -	20

All theſe allowance are payable quarterly, and the coals delivered at Michaelmas. A diet table is alſo preſcribed. The whole charity now conſiſts of a maſter and miſtreſs, and 20 in-penſioners, *viz.* 10 men, of whom one is the warden, and 10 women, of whom one is the matron, whoſe allowances have been lately increaſed; five men and five women, as out-penſioners: alſo ten boys and ten girls, who are in-penſioners, and have a ſchool-room, who are all apprenticed to trades, with a premium of 10*l.* half paid at the time of binding, and the other moiety when they have ſerved half their apprenticeſhip.

HOSPITAL, *Fever.* See HOUSE *of Recovery.*

HOSPITAL, *Foundling*, was eſtabliſhed, at the ſolicitation of Thomas Coram, eſq. by royal charter, in the 13th year of George II. and incorporated by the name of "The governors and guardians of the hoſpital for the maintenance and education of expoſed and deſerted young children:" and the powers granted by charter were enlarged and confirmed by a ſtatute of the ſame year. The corporation of this hoſpital is allowed to purchaſe lands or tenements to the yearly value of 4000*l.* This charity is under the management of a preſident, the king being patron; ſix vice-preſidents, treaſurer, and governors. The ſubordinate officers are a chaplain, morning preacher, evening preacher, ſecretary, ſolicitor, matron, ſchool-maſter, treaſurer's clerk, and organiſt. This hoſpital has two phyſicians, a ſurgeon, and apothecary. In 1742 the noble building in Lambs-conduit fields for the uſe of this hoſpital was begun to be erected; one wing was finiſhed in 1745; the chapel was begun in 1747; and in 1749 orders were given for building the other wing of the hoſpital, which, together with the treaſurer's houſe, was ready for habitation in 1752. The whole building was originally calculated to hold 400 children; and the talents of ſeveral eminent artiſts were employed in contributing to its embelliſhments; among whom were Mr. Hogarth, Mr. Hayman, Mr. Highmore, Ryſbrack, &c. Mr. Handel, upon the building of the chapel, gave an organ, and the benefit of his oratorio of the Meſſiah, the performance of which was conducted by himſelf: this he repeated ſeveral years, which produced to the charity 6700*l.* and by his will he bequeathed to it his property in the muſic. Before the end of the year 1752 the hoſpital had received 1040 children, of whom 559 were then under its protection; but the expence far exceeding the income, application was made to parliament for aſſiſtance; and in 1756 the houſe of commons, after paſſing three introductory reſolutions, voted 10,000*l.* in conſequence of which, before the 31ſt of December 1757, during an interval of little more than a year and a half, the number of children that were received amounted to 5510. Large ſums were afterwards granted, and the number of infants, in 1760, increaſed to 6000, which they had no adequate income to maintain. The corporation received continual parliamentary aſſiſtance, during 15 years, till 1771, when it ceaſed, at an average of not leſs than 33,000*l.* per annum; and the number of children in 1769 was reduced to 1000, by apprenticing all who could be placed out. The country hoſpitals were diſcontinued, and the eſtabliſhment reduced to its permanent income. The improvement of the revenue by granting building leaſes of the lands, belonging to the hoſpital, was the next method adopted. Ten acres of the 56 purchaſed of lord Saliſbury had been occupied by the hoſpital and its conveniences; and after ſeveral delays and demurs, it was agreed, in 1788, that the ground which lay ſouth of and adjoining to the road leading from the gates of the hoſpital to Gray's Inn-lane ſhould be let on building leaſes. In the years 1783, 1793, and 1794 the plan of building leaſes was fully adopted, and in ſubſequent years carried on very much to the embelliſhment of the vicinity of the hoſpital, and to the improvement of its revenues. The emoluments ariſing from theſe improvements, and from the increaſe of governors and benefactions, have enabled this corporation to replace the ſtock which they had been under a neceſſity of parting with for the ſupport of the charity, to repair the hoſpital, to liquidate its outſtanding debts, and at the ſame time gradually to enlarge the eſtabliſhment of its children; and it affords the moſt encouraging proſpect of farther augmentation. The ordinary age of reception of children is under two months, and upon the hearing of the petitions, the character and exigency of the mother, and deſertion of the father, are inveſtigated. The age, after which children cannot be received, is 12 months, unleſs they are the children of ſoldiers and ſailors, the time of whoſe reception is extended to five years of age. The children, after admiſſion, are numbered and regiſtered, and their billets made up; for this purpoſe the ſecretary writes a number on a ſlip of parchment, and affixes it to their clothes; and great care is taken that theſe numbers remain fixed to the children whilſt they continue at nurſe: he then makes up the billet, which contains the number, ſex, and ſuppoſed age, the date of reception, and any particular writing or token brought with the child, which is alſo marked with its number. The billet is marked on the outſide with the number, date, and letter M or F to diſtinguiſh the ſex. Theſe billets, being the only means which can enable the governors to know the children, in caſe they ſhould be enquired for, are kept with great ſecrecy and care, and are never opened but by order of the general committee. After regiſtry and baptiſm, the children are committed to the care of inſpectors, who find out proper nurſes, and ſuperintend their conduct: when the children attain the age of four or five years, and not before, they are remanded to the hoſpital, when the ſecretary returns receipts for them to the inſpectors; and they are then inoculated or vaccinated. The mortality of children, committed to the care of nurſes, is very ſmall; the average of thoſe who died under 12 months in 10 years, being only one in ſix, and for the laſt four or five years even leſs than that proportion.

The children admitted to this hoſpital are not only nurſed, but educated and employed under proper regulations, and provided with all neceſſaries, till they attain the age appointed by parliament for their diſcharge, *viz.* twenty-four for males, and twenty-one for females, unleſs they be previouſly married with the conſent of the committee: at ſuch time, the general committee, at their diſcretion, may give them cloaths, money, or neceſſaries, not exceeding the value of ten pounds. In the mean while, the corporation of the hoſpital may employ the children educated and maintained here in any ſort of labour, or manufacture, or in the ſea ſervice; and bind ſuch children apprentices, or place them out as ſervants, or mariners, to any huſbandman, maſter or captain of a ſhip, or other perſon, until the aforeſaid reſpective ages. The girls are diſtributed into three claſſes, under the care of three different miſtreſſes, by whom they are taught needle-work, and reading, to aſſiſt in the houſe-work, kitchen, and laundry, &c. The boys are put out apprentices at twelve or thirteen years of age, and the girls at fourteen; and they are diſpoſed of with great attention on the part of the committee. The reports as to their ſubſequent conduct, which is particularly inquired into, have been very favourable. By a report of ſir T. Bernard in 1798 it appears, that out of 252 apprentices, 166 were doing well; and of the remaining 86, 15 had turned out ill, partly through their own fault and partly through that of their maſters. The proportion of good ſervants in place and good apprentices far exceeds the number of the others; and there are many reſpectable perſons at preſent in London, married and ſettled in buſineſs, who have been nurſed, educated and apprenticed by this charity. By an attention to cleanlineſs and diet the children have of late been more healthy than formerly.

Hospital, *French*, in the pariſh of St. Luke, was erected in the year 1716; and the governors of it, by letters patent of Geo. I. anno 1718, were conſtituted a body politic and corporate, by the appellation of "The governor and directors of the hoſpital, for poor French Proteſtants and their deſcendants, reſiding in Great Britain."

This inſtitution owes its riſe to the charity of M. de Caſtigny, maſter of the buckhounds to king William III., as prince of Orange, who bequeathed 1000*l.* for a building and its maintenance. The intereſt of this ſum was permitted to accumulate, and aided by voluntary contribution; ſo that a fund was raiſed ſufficient to erect a building for the accommodation of about 80 poor perſons. The corporation, by the ſubſequent contributions of benevolent refugees and others, has been enabled, at different times, to enlarge the buildings, ſo as to admit 200 poor, who are either very aged, or diſordered in mind or body. They are ſupplied with every neceſſary for their ſubſiſtence and relief. The government of this hoſpital is veſted in a governor, deputy-governor, and 37 directors. The governor remains in office three years; the deputy-governor is choſen for one year; alſo a treaſurer, ſecretary, and miniſter. Eight directors are choſen at the four quarterly courts to conſtitute a committee, who meet at the hoſpital every Saturday. Five viſitors are choſen annually from among the directors, who, with the phyſician and ſurgeon, make a general viſit in June, and report the ſtate of the whole inſtitution to the next court. The treaſurer and ſecretary are choſen annually: the miniſter performs divine ſervice in the chapel of the hoſpital, and viſits the ſick at leaſt once a week. The phyſician attends regularly once a week, and at any other time when required. The ſurgeon and apothecary attend at leaſt three times in the week. The ſteward has the ſuperintendance of the houſe and family. The chapel is commodious, in which an annual ſermon is preached upon Wedneſday next before Eaſter for the benefit of the hoſpital. The number of beds is 200, but that of patients is much leſs conſiderable.

Hospital, *St. George's*, near Hyde-park Corner, was inſtituted in 1733 for the relief of the poor ſick and lame, who are ſupplied with advice, medicine, diet, waſhing, lodging, and ſome of them alſo with cloaths. This hoſpital is under the direction of a general board of the governors, now amounting to about 350, who meet regularly five times a year, and a committee of which meets every Wedneſday to admit and diſcharge patients, and tranſact the buſineſs of the hoſpital. The qualification for a governor is 5*l.* 5*s.* as an annual ſubſcription, or 50*l.* as a ſingle benefaction. The king is preſident, there are ſix vice-preſidents, two treaſurers, four phyſicians, four ſurgeons, and two aſſiſtant ſurgeons, ſix viſiting apothecaries: the domeſtic officers are a chaplain, apothecary, ſecretary, matron, and meſſenger. Beſides the patients that are admitted into the houſe, relief is afforded to a conſiderable number of out-patients. By the account of the year 1808, it appears that from the firſt inſtitution the patients diſcharged amounted to 209,430, and the number of patients relieved in that year was 2717; 1596 being in-patients, and 1121 out-patients. The whole expence during the ſame year amounted to 5880*l.* 0*s.* 8*d.* The annual ſubſcriptions are ſtated at 2378*l.* 9*s.* To this hoſpital is annexed another inſtitution denominated "The Charity for Convaleſcents of St. George's Hoſpital," and eſtabliſhed in the year 1809.

Hospital, *Greenwich*, is a retreat for ſeamen, who, by age, wounds, or other accidents, are diſabled from ſervice; and for the widows and children of ſuch as are ſlain in the ſervice.

This, in point of magnificence and ſpacioufneſs, greatly excels even Chelſea hoſpital. King William and queen Mary had the benevolent deſign of eſtabliſhing this hoſpital much at heart; and they accordingly made a grant of the royal palace at Greenwich, a part of which, on the weſt ſide, had been begun to be rebuilt for a royal palace by king Charles II., and alſo of a large adjoining ſpace of ground, for this purpoſe. King William, after queen Mary's death, on the 25th of October 1695, appointed by patent a number of commiſſioners for directing the building and endowing of this intended hoſpital, and granted a large ſum out of his civil liſt for that end, and his royal ſucceſſors were alſo conſiderable benefactors to it. At length annual ſums were granted by parliament for finiſhing this truly magnificent ornament and glory of Great Britain: and it was fully completed in the reign of George II. By an act of the 7th and 8th of king William, cap. 21. the privilege of admiſſion into this hoſpital was granted to regiſtered ſeamen, when maimed or ſuperannuated, and to the widows and children of thoſe who were killed in the ſervice. This act for regiſtering ſeamen was enforced by 8 and 9 W. III. cap. 22. but repealed by 9 Anne. Every ſeaman is required to allow out of his wages ſixpence a month, for the better ſupport of the ſaid hoſpital; for which duty receivers are appointed, &c. The money is paid into a receiver's office on Tower-hill, which is under the management of three commiſſioners and their clerks. (8 and 9 W. III. cap 23. 10 Anne. 2 Geo. II. cap. 7.) By the laſt act a ſeaman, abſenting himſelf from his ſhip without leave, ſhall forfeit for every day's abſence two days' pay to Greenwich hoſpital to be deducted out of his wages: and a ſeaman, not entering into the king's ſervice, who ſhall leave his ſhip before he hath a diſcharge in writing, ſhall forfeit one month's pay in like manner.

By 8 Geo II. cap. 29, the net rents and profits of the eſtates forfeited by the attainder of James late earl of Derwentwater, and of Charles Radcliff, were applied in the firſt place to the completing of the building of Greenwich hoſpital; and it is hereby enacted, that all ſeamen in the merchant's ſervice who ſhall happen to be maimed in fighting, not only againſt pirates, but againſt an enemy of his majeſty, &c. ſhall be admitted into and provided for in the ſaid hoſpital, as well as ſeamen maimed or diſabled in the king's actual ſervice: and in the next place, the whole net rents of thoſe forfeited eſtates ſhall be for ever applicable for the ſupport of the ſaid royal hoſpital, for the better maintenance of the ſeamen therein, worn out and become decrepit in the ſervice of their country. This law was farther explained and amended by 11 Geo. II. cap. 30.

Proviſion is made for ſecuring the payment of the ſixpence per month from privateers by 18 Geo. II. cap. 21. and for ſecuring prize money belonging to the hoſpital by 20 Geo. II. cap. 24. The governors are empowered to grant out-penſions to decrepit ſeamen, by 3 Geo. III. cap. 16.; and perſons perſonating or falſely aſſuming the name and character of out-penſioners, ſhall be guilty of felony without benefit of clergy: and thoſe who receive half-yearly penſions ſhall, together with the printed bill delivered to them by the commiſſioners, produce a certificate under the hand of the miniſter and church-wardens, where they reſide, teſtifying that they are the perſons named in ſuch bill.

The penſioners belonging to this hoſpital are cloathed in blue, and allowed ſtockings, ſhoes, linen, and a ſhilling a week for other neceſſaries. The victualling is according to the allowance of Chelſea hoſpital, *viz.* four men to a meſs, each meſs to contain four pounds of fleſh, a gallon of beer, &c.

The governors of this hoſpital are the great officers of ſtate, and perſons in high poſts under the king; and it is under the more particular inſpection and government of twenty-four commiſſioners, a governor with an annual ſalary of 1000*l.* and clerk; a lieutenant-governor, whoſe ſalary is 400*l.* a-year; four captains, allowed 230*l.* a-year each; and ſeven lieutenants, with 115*l.* a-year each; a treaſurer, whoſe ſalary is 200*l.* with two clerks; ſecretary with 160*l.* a-year and clerk, auditor, whoſe annual ſalary is 100*l.* and clerk, ſurveyor with 200*l.* ſalary, clerk of works at five ſhillings a day, a phyſician at ten ſhillings a day, a ſurgeon with an annual ſalary of 150*l.* a ſervant and two aſſiſtants, diſpenſer with 50*l.* a-year and his aſſiſtants, two chaplains with a ſalary of 130*l.* each, ſteward with a ſalary of 160*l.* and three clerks; clerk of cheque with 100*l.* ſalary and three clerks; brewer, three matrons, organiſt, meſſenger, two chief cooks and four mates, ſcullery man and two mates, butler and two mates, porter and barber. For a particular account of the building and its eſtabliſhment, ſee Greenwich. The cheſt at Chatham is now under the management of the governors of this hoſpital. See Chest.

Hospital, *Guy's*, ſituated in the pariſh of St. Thomas, Southwark, was founded in his life-time, by Thomas Guy, eſq. a very wealthy citizen and bookſeller of London. For this purpoſe he took a leaſe of a piece of ground belonging to St. Thomas's hoſpital, for the term of 999 years, at a ground-rent of 30*l.* per annum; the foundation of the intended hoſpital was laid in 1722, and the fabric was roofed before the death of the founder, which happened in the year 1724. The charge of erecting and furniſhing this hoſpital amounted to the ſum of 18,793*l.* 16*s.* 1*d.* and the ſum left to endow it was 219,499*l.* 6*s.* 4*d.* and upwards. The governors of this hoſpital were incorporated by act of parliament, made in the 11th year of Geo. I. anno 1725, under the title of "The Preſident and Governors of the Hoſpital founded at the ſole coſt and charges of Thomas Guy, eſq." and under this title they are empowered to purchaſe, either in perpetuity or for a term of years, any eſtate not exceeding 12,000*l.* per annum. The number of governors appointed to be choſen from thoſe of St. Thomas's hoſpital, by the founder, is 60; and it is enacted that if the number does not exceed 40, the vacancies ſhall be ſupplied by the lord chancellor, lord keeper, or commiſſioners of the great ſeal, lords chief juſtices of the king's bench and common pleas, and lord chief baron of the exchequer, ſo as to make up the number of 50. It is alſo enacted, that the management of the hoſpital be referred to a preſident, treaſurer and 21 governors; forming a committee appointed by a general court, ſeven of whom are annually changed; this committee is impowered to chuſe, and at pleaſure to remove, all officers and ſervants employed in the hoſpital, except the phyſicians, ſurgeons, clerk, and chaplain, who are elected by the general court, to appoint their ſalaries, to admit objects of charity, and in general to tranſact the affairs of the hoſpital ſubject to the inſpection and controul of a general court; and this general court has power to make any by-laws for the better government of the corporation. This hoſpital, ſo liberally endowed by its founder, was eſtabliſhed for the reception and relief of upwards of 400 ſick and diſeaſed poor objects; beſides twenty incurable lunatics, who are provided for in a ſeparate building. Since the deceaſe of Mr. Guy, the governors have taken a leaſe of an additional ſpot of ground, for which, with the former, they annually pay to St. Thomas's hoſpital the ſum of 100*l.* On this ground they have erected two handſome wings; in the centre of one wing there is a ſpacious hall and rooms for public buſineſs, and oppoſite to it in the other a neat and elegant chapel, in which there is a finely executed ſtatue of the founder by Mr. Bacon. The corner houſe in one wing is for the reſidence of the treaſurer, and the other houſes are for the chaplain, ſteward, and apothecary. This hoſpital is under the medical inſpection of three phyſicians and three ſurgeons, who are allowed 40*l.* a-year each, an apothecary, who has 90*l.* a-year for himſelf and aſſiſtant, and a houſe. The officers are a clerk, chaplain, ſteward, accomptant, matron, butler, and aſſiſtant; ſurgery man, porter, beadle, keeper of the lunatic men, and a keeper of the lunatic women. It contains 13 wards and 411 beds; and the number of patients admitted into this hoſpital, at an average of ten years, has been 2244 yearly; of whom 2014 have been diſcharged, and 230 have died: under the prudent conduct of the treaſurer and governors, it does great honour to the liberality of its founder. The day of admiſſion to this hoſpital is Wedneſday. To this hoſpital belongs a theatre for chemical, medical, and anatomical lectures. On one evening in the week medical ſubjects are debated for the improvement of the ſcience and practice. A library is alſo a part of this eſtabliſhment, well furniſhed with profeſſional works, and a collection of anatomical preparations. We ſhall add under this article, that Mr. Guy (ſee Guy) has bequeathed to the preſident and governors of Chriſt's hoſpital, a perpetual annuity of 400*l.* for taking into the ſaid hoſpital four children yearly, at the nomination of the governors of his hoſpital: preference being always given to his own relations, who have never failed to offer themſelves. To his poor aged relations he gave annuities during life to the amount of 870*l.* and among his younger relations and executors the ſum of 75,589*l.* together with the ſum of 1000*l.* for diſcharging poor priſoners, within the city of London, and counties of Middleſex and Surry, who could be releaſed for the ſum of five pounds.

He likewiſe erected an alms-houſe, with a library at Tamworth, where his mother reſided, and which he repreſented in ſeveral parliaments, for the uſe of 14 poor men and women; to whom he allowed certain penſions during life, and at his death, for their future ſupport and putting out children apprentices, &c. he bequeathed a perpetual annual ſum of 115*l.* Mr. Guy alſo built and furniſhed, at his own expence, in the year 1707, three wards on the north ſide of the outer court of St. Thomas's hoſpital; and gave to the ſame 100*l.* per annum, for eleven years immediately preceding the foundation of his hoſpital. Some time before his death, he removed the frontiſpiece of the ſaid hoſpital of St. Thomas, which ſtood over the gate-way in the borough, and erected the ſame in the place where it now ſtands, fronting the ſtreet; and having enlarged the gate-way, rebuilt the two large houſes on the ſides thereof, and erected the ſtately iron-gate between them, at an expence of between 2 and 3000*l.* To many of his relations he gave ſtated allowances of 10 or 20*l.* per annum, and to others, money for advancing them in the world.

Hospital *of Jeruſalem.* See Hospitaler.

Hospital, *Jews*, called בת הולים, *Beth-holem*, or houſe for relief of the ſick, was founded by ſubſcription in 1748. It was firſt eſtabliſhed in Leman-ſtreet, Goodman's-fields. This charity, which adminiſters medicines and advice gratis, was maintained by a certain ſum allowed by the ſynagogue, and private contributions, amounting, ſoon after its firſt eſtabliſhment, to about 500*l.* a-year. An enlargement becoming neceſſary, a more commodious building was erected in 1792 at Mile-end, Old-town, which contains accommodation for 14 ſick men, and as many ſick women, and for eight lying-in women; beſides 21 beds for the old and indigent. The beds for the ſick are in four wards, thoſe for lying-in women in a ſeparate apartment, and thoſe for the old and indigent in ten rooms, with a long-ſitting room, which has two fire-places. The contributions for the ſupport of this charitable inſtitution are general throughout the Portugueſe congregations by offerings made at the ſynagogue, and their elders grant from their general charity fund from 270 to 300*l.* annually towards its ſupport; they have alſo a ſmall capital in the funds. This hoſpital diſpenſes medicines to all perſons who hold any employment under their ſynagogue, and to all the poor of their congregation.

Hospital, *German and Dutch Jews*, נוה צרק, *Navay Tzadek, i. e.* dwelling-place of juſtice or of charity, an eſtabliſhment ſituated in Mile-end, Old-town, of wider extent than that of Beth-holem, which aroſe from the philanthropic exertions of Benjamin and Abraham Goldſmid, eſqrs. who, in 1795, commenced a collection among their friends for the purpoſe of relieving the poor of the claſs denominated German Jews. The ſums contributed by Jewiſh and Chriſtian benevolence enabled them, in 1797, to purchaſe 20,000*l.* imperial annuities of three per cent. and by accumulation of intereſt and increaſe of donations, the aggregate ſum, in 1806, amounted to the value of 22,000*l.* ſtock, at the current price of that period. After previous deliberation it was agreed to erect an hoſpital for the reception and ſupport of the aged poor, as well as for the education and induſtrious employment of both ſexes. Ten thouſand pounds of three per cent. conſols bank-annuities were purchaſed, and this ſum, together with the former ſtock, was transferred to truſtees as an inviolable fund for its endowment, yielding 900*l.* per annum. In February, A.D. 1806, the freehold on which the hoſpital was afterwards erected, was purchaſed for 2300*l.*; the houſe was completed and opened in June, 1807, for the reception of five aged men, five aged women, 10 boys, and eight girls. The adjoining freehold was alſo purchaſed for 2000*l.* in which it is further propoſed to erect an enlargement of the hoſpital for the admiſſion of an additional number of patients. Two gentlemen, *viz.* Dr. Myers, and Mr. Van Oven, offered to fulfil the duties of phyſician and ſurgeon gratis: 25 guineas conſtitute a governor for life: 10 governors are competent for buſineſs; and at general meetings held in March, officers are elected, and alſo a houſe-committee of 24, and two auditors. This inſtitution is under the management of a general committee of 12 governors, which attends at the hoſpital on Sunday, weekly. None are conſidered as proper objects of this charity who do not belong to one of the three eſtabliſhed ſynagogues of German Jews in London; nor can any be admitted under 55 years of age. The boys are admitted from 10 to 13 years of age, and maintained till the expiration of their apprenticeſhip. The girls are admitted from 7 to 10 years of age. The preſent officers are, a patron, preſident, two vice-preſidents, two treaſurers, a phyſician, ſurgeon, ſolicitor, and ſecretary.

Hospital, *Lock*, (*lock* being derived from *loke*, a houſe for lepers,) near Hyde-park corner, was inſtituted in the year 1746, for the relief of venereal patients only. Every gentleman ſubſcribing five guineas a year, or upwards, ſhall be a governor of this hoſpital, and whoever gives a benefaction of fifty-pounds at one time becomes a governor for life. This hoſpital is under the direction of a preſident, ſeven vice-preſidents, two treaſurers, and a committee of the governors, who meet every Thurſday for the buſineſs of the inſtitution. It is attended by a phyſician, two ſurgeons, and two viſiting apothecaries. The officers are a chaplain, houſe-ſurgeon, ſecretary, collector, and matron. By a report circulated in November 1809, it appears that the number of patients perfectly cured to that time amounted to 30,577; many perſons of both ſexes were thus reſtored to their families, who might otherwiſe have lingered out a loathſome and miſerable exiſtence; many abandoned characters were reclaimed by the religious inſtructions afforded them; and the progreſs of the contagious diſeaſe, dreadful to the ſufferer and deſtructive to poſterity, was materially arreſted. The *Lock Aſylum* is an appendage to the hoſpital, which provides for females after cure, who have no means of accommodation and ſupport when they leave the hoſpital, and who might otherwiſe be urged by neceſſity to return to that courſe of vice and infamy which they have abandoned. This inſtitution has been found of ſingular utility. The number of women admitted to this aſylum from July 1787 to Lady-day 1809, has been five hundred, many of whom have been preſerved from ruin, and rendered uſeful members of the community. The aſylum is under the ſuperintendance of a patron, preſident, three vice-preſidents, a chaplain, and ſecretary.

Hospital, *London*, in Mile-end road, was inſtituted in 1740, principally by the inſtrumentality of John Harriſon, eſq., its firſt ſurgeon, and incorporated in 1759, 32 Geo. II. This hoſpital, which was firſt founded in Preſcott-ſtreet, Goodman's fields, is now ſupported, in a very large and commodious building, by voluntary contributions, for the relief of all ſick and wounded perſons.

The in-patients are ſupplied with advice, medicine, diet, lodging, waſhing, and every other kind of comfortable aſſiſtance: the out-patients receive medicines and advice daily. None are admitted into the hoſpital with infectious diſtempers, or the venereal diſeaſe, or who are aſthmatic or conſumptive, or deemed incurable or improper for admiſſion by the phyſicians or ſurgeons; but ſuch perſons may be relieved as out-patients. The average number of patients in this hoſpital at any one time is about 180, but its wards are 18 in number, and would contain nearly 400. This hoſpital has ſubſiſted during a period of 68 years, and in that time has relieved 507,802 to Jan. 1, 1809, which is an average of 7466 perſons in each year. During the year 1809, the in-patients amounted to 1406, and the out-patients to 877. The governors, in 1807, made an intereſting appeal to the benevolence of the public, and with ſuch ſucceſs, that the committee were enabled immediately to diſcharge the hoſpital debts, amounting to 3824*l.* 10*s.* 11*d.* In conſequence of farther liberal contributions, they began with the admiſſion of 37 in-patients, and they have ſince been progreſſively augmenting the eſtabliſhment, according to the extent of their power. The funds of the hoſpital, at the cloſe of the year 1808, conſiſted of 3000*l.* bank-ſtock, 225*l.* 5 per cent. navy ſubſcription of bank on bank-ſtock, 1804; 200*l.* 4 per cent., 65,292*l.* 12*s.* 2*d.* 3 per cent. conſols; 9779*l.* 9*s.* 8*d.* 3 per cent. reduced; 400*l.* 3 per cent. O.S.S. ann.; 450*l.* 3 per cent. New ditto.; 310*l.* India ſtock; 571*l.* 16*s.* South Sea ſtock; 500*l.* 3 per cent. 1726; 50*l.* bond; 338*l.* 8*s.* 8*d.* caſh; land and houſes near the hoſpital *ad valorem.*

The charity is under the government and direction of a preſident, five vice-preſidents, a treaſurer, and of ſuch perſons, who, by giving a benefaction of thirty guineas or more at one time become governors for life; or who ſubſcribe five guineas or more per annum. A houſe-committee of thirty governors is annually appointed at the quarterly court, in December, one of whom is choſen chairman; and they meet every week at the hoſpital to tranſact the neceſſary buſineſs.

There is alſo a committee of accounts, conſiſting of twelve governors, appointed at the quarterly court in June for one year, who meet there quarterly to examine and audit the bills and accounts, and a medical committee alſo conſiſting of twelve governors, elected annually at the court in December, who examine all the medicines and drugs. The management of the houſe is inſpected by two governors, appointed viſitors by the houſe-committee. Three phyſicians and three ſurgeons attend this hoſpital: the officers are a chaplain, apothecary, ſecretary and receiver, ſteward and matron. Every governor is entitled to ſend one in-patient at a time, and four out-patients. Subſcribers, that are not governors, may ſend out-patients; the day of admiſſion is Tueſday.

The "Samaritan Society" is an appendage to the London Hoſpital, inſtituted A.D. 1791, for the relief and prevention of various circumſtances of diſtreſs, not within the proviſion of public hoſpitals, and depending upon donations and bequeſts. Annual members contribute one guinea, and benefactions of five guineas conſtitute members for life. The affairs of this ſociety are conducted in the conſulting-room of the hoſpital, allotted in 1792 for its meetings and buſineſs, by a committee of nineteen for general purpoſes; a committee of ſeven for public communications and correſpondence; ſeven auditors, a treaſurer, an almoner, a ſecretary, and collector.

Hospital, *St. Luke's, for Lunatics*, in Old-ſtreet Road, was inſtituted in 1751. The new extenſive building for this hoſpital was erected at an expence of 5000*l.* raiſed by voluntary contributions, upon leaſehold ground belonging to St. Bartholomew's hoſpital: the leaſe is held for a term of 40 years, renewable every fourteen years, on payment of a fine of 200*l.* and at the yearly rent of 200*l.* It was completely finiſhed at the cloſe of the year 1786; and on the 1ſt of January, 1787, the patients were removed into it. The houſe accommodates 300 patients, who are diſtinguiſhed by two liſts or claſſes, 200 on the curable liſt, and 100 on the incurable liſt.

It appears, from the printed ſtate of this hoſpital, that the number of patients received into it from the opening on the 30th of July, 1751, to the 21ſt of April, 1809, incluſive, amounted to 9042, of whom thoſe diſcharged uncured and received again at 7*s.* a week, are 323. Of theſe 3915 have been diſcharged cured, and 3101 diſcharged uncured, 783 diſcharged as idiots, 748 died, and 251 taken away at the deſire of friends. Of the incurable, 56 were taken away at the deſire of friends, 145 died, and 18 were cured.

The property of the hoſpital conſiſts of the building and premiſes in Old-ſtreet; 64,000*l.* conſol. 3 per cent. annuities; 38,100*l.* reduced annuities; 22,500*l.* Old South Sea annuities; 5000*l.* 4 per cent. annuities; 220*l.* New South Sea annuities; 1000*l.* reduced annuities; divers legacies unreceived, beſides contingent and reverſionary legacies; an annuity of 5*l.* 5*s.* and another of 100 guineas by the late Samuel Whitbread, eſq. The income of this property is conſiderably increaſed by caſual benefactions and legacies, and by caſh received from the board of incurables, all which, with a balance in hand, amounted, in 1808, to 9053*l.* 16*s.* 3*d.*, and the expenditure amounted in the whole to 7934*l.* 17*s.* 3*d.*

Perſons paying the entire ſum of twenty-guineas or upwards, or paying ſeven guineas at leaſt, and ſigning an agreement to pay 3*l.* 18*s.* yearly, for the four next ſucceeding years, are admitted governors of this hoſpital; nine of whom conſtitute a general court, held on the third Wedneſday in February, every year. At this court one preſident, four vice-preſidents, a treaſurer, a general committee, phyſician, ſurgeon, reſident, apothecary, ſecretary, maſter, matron, and accountant, ſhall be elected for the enſuing year. The general committee conſiſts of the preſident, vice-preſidents, and treaſurer, and of five governors, named as leſſees in the leaſe of the ground on which the hoſpital is built, and of all perſons who pay in their own right 100*l.* or upwards, who are ſtanding members of it, and of ſuch other thirty governors reſident in the bills of mortality as are elected at the court in February.

The general committee meets monthly or oftener, if neceſſary, and is empowered to tranſact all the neceſſary buſineſs of this hoſpital, and to appoint a houſe-committee and ſub-committees. The phyſician and ſurgeon attend on every committee day, and one other day in the week, and as often as occaſion requires. The reſident apothecary is precluded from any other practice. No fees are taken by any officer. Patients are admitted into this hoſpital according to the order of time in which their petitions, previouſly ſigned by a governor, have been delivered to the ſecretary, and without any expence, except that the pariſh poor ſhall provide their bedding, which they may take away at their diſcharge. But no perſon can be admitted into this hoſpital who is not poor and mad; or who hath been a lunatic more than twelve calendar months; or who hath been diſcharged uncured from any other hoſpital for the reception of lunatics, or who is troubled with epileptic or convulſive fits; or who is deemed an idiot; or who is infected with the venereal diſeaſe; nor any woman with child; nor any child under the age of twelve, nor any perſon above the age of ſeventy years. Beſides a petition, the governors require two printed certificates; one teſtifying the above particulars, ſigned by the miniſter and churchwardens, or overſeers of the poor of the pariſh or place where the propoſed patient reſides; and the other to the ſame purpoſe, ſigned by ſome phyſician, ſurgeon, or apothecary, who hath viſited ſuch patient; which ſignatures muſt be atteſted upon oath.

Upon notice being ſent from the committee for the patient to be brought for examination, there muſt be left in writing with the ſecretary, within three days afterwards, the names, buſineſs, and place of abode of two ſubſtantial houſekeepers, reſiding within the bills of mortality, who muſt be preſent preciſely at the hour when the patient (not being pariſh-poor, or receiving alms or ſupport from any public body or community) is to be admitted upon the payment of three pounds; and if ſuch patient be pariſh-poor, or has received alms or ſupport from any public body or community, then upon the payment of ſix pounds, and to enter into a bond of one hundred pounds to take away the patient when diſcharged by the committee; which ſums of three pounds and ſix pounds are not returnable unleſs the patient dies or is diſcharged within one month after admiſſion.

It is alſo provided, that the general committee may receive immediately into this hoſpital any patient who ſhall have been diſcharged cured, in caſe ſuch patient relapſe within two months; and that ſuch patients who have been diſcharged uncured, not exceeding 100, ſhall be admitted by rotation; on condition of the payment of ſeven ſhillings per week for each, till the charity ſhall be enabled to leſſen that expence. The patients are not expoſed to view; but their friends are allowed to viſit them every Wedneſday morning.

Hospital, *Lying-in.* There are ſeveral hoſpitals of this kind in the cities or ſuburbs of London and Weſtminſter.

The *Queen's* lying-in hoſpital was founded in 1752 for the purpoſe of receiving poor pregnant women, as well married as unmarried, in ſeparate wards, and alſo of attending them at their own habitations, within a limited circuit. It is now fixed at a houſe in Bayſwater; and the government of the charity has been veſted in a preſident, four vice-preſidents, a treaſurer, and a committee of eighteen governors. An annual ſubſcription of three guineas conſtitutes a governor, entitled to recommend one in-patient, two to be delivered at their own habitations, and ſix for advice; and a ſubſcription of 31 guineas at one payment, entitles to the recommendation of one in-patient, ſix at their own habitations, and twelve for advice, yearly. It is computed that upwards of 45,000 women have received the benefit of this hoſpital in its reſpective branches.

Quarterly meetings are held at the hoſpital; and the committee meet every Tueſday. This hoſpital was renovated in October 1809, and under the active exertions of its preſident the duke of Suſſex, has now a fair proſpect of permanent utility. Her majeſty is patroneſs, and it is under the care of a conſulting phyſician, and phyſician in ordinary, a ſurgeon and man-midwife, an apothecary and ſecretary, a matron, nurſes, and collector.

The *Middleſex* hoſpital for ſick and lame, and lying-in married women, in Mary-le-bone Fields, was inſtituted for the firſt deſcription of patients in 1745, and for the ſecond in 1747; and for patients afflicted with cancer in 1792. It is under the direction of a patron, a preſident, 12 vice-preſidents, two treaſurers, and a committee of the governors; the qualification for a governor is an annual ſubſcription of three guineas, and of a governor for life 30 guineas at one payment. A quarterly general court is held four times in the year. All general courts and weekly boards may appoint committees for carrying on the buſineſs: 24 governors are appointed for a weekly board to meet every Tueſday; and 12 for a medical committee, including the phyſicians, man-midwife, and ſurgeons, to meet every Saturday. The preſident, vice-preſidents, treaſurers, chaplain, phyſicians, man-midwife, ſurgeons, apothecary, ſecretary, collector, and matron, are elected at a quarterly or ſpecial general court. The lying-in ward in this hoſpital has no communication with thoſe of the ſick and lame. The patients are viſited by three phyſicians, an accoucheur, and three ſurgeons, beſides the phyſician and ſurgeon of the cancer-ward. The domeſtic officers are a chaplain, ſecretary, apothecary, and matron, who reſide in the houſe, have ſalaries, and are provided with lodging, waſhing, and board. The houſe-ſurgeon alſo reſides in the hoſpital, under certain ſtipulated regulations. A ſufficient number of midwives to attend women at their own habitations is provided. The day for admiſſion of patients is Tueſday.

The *Britiſh* lying-in hoſpital for married women, in Brownlow-ſtreet, Long-acre, was inſtituted in 1749. This hoſpital is governed by a preſident, four vice-preſidents, a treaſurer, and a committee of 15 governors, who meet every Friday to receive the women recommended, and to direct the ordinary affairs of the houſe. The qualification of an annual governor is a ſubſcription of five guineas or upwards per annum, and of a perpetual governor a ſingle payment of 40 guineas, each of whom may preſent two women in the year. This hoſpital is occaſionally viſited by three phyſicians, and one ſurgeon; and it is provided with an apothecary, chaplain, ſecretary, matron, and midwife, ſix nurſes, and 62 beds. Female pupils, being widows or married women, not leſs than 25 years of age, and of approved character, are permitted to attend this hoſpital, for inſtruction in midwifery, and have a right to ſtay in the hoſpital ſix months. They are to board in the hoſpital, and dine at the ſteward and matron's table; and on leaving the hoſpital to receive certificates of their qualification. The expences of inſtruction and board are ſettled by a general court. The ſtock of this charity in the public funds amounts to 2092*l.* 10*s.* and its expenditure is about 1100*l.* a-year, for which they have the dividends of the above-mentioned ſtock, and annual ſubſcriptions of about 900*l.* per annum, beſides benefactions and legacies, and board of women, who reſide in the hoſpital before and after the period of three weeks, allowed for their lying in and recovery, and pupils. The committee of this hoſpital have preſerved an account of thoſe who have died, from which it appears that in the firſt 10 years of the inſtitution one woman died in 42; in the fifth 10 years, one died in 288; in the ſixth and laſt 10 years, one in 216; and from the 20th of September, 1806, to the 25th of March, 1808, not one woman died out of 501. In the firſt 10 years one child died in 15; in the fifth 10 years one died in 77; and in the laſt nine years and a quarter, one died in 92. The proportion of boys to girls born is about 18 to 17; of ſtill-born, about one to 25; of women bearing twins, one to 84, the whole number being 342. If ſimilar tables were preſerved by other inſtitutions of a like kind, they would furniſh uſeful data in calculations relating to population and political economy.

The city of London lying-in hoſpital for married women, in the City road, was inſtituted in 1750. The government of this hoſpital is referred to a preſident, 12 vice-preſidents, and a treaſurer, choſen annually from among the governors and ſelect committees. The ſubſcription of 30 guineas conſtitutes a governor for life; thoſe who ſubſcribe five guineas, or three guineas per annum, are governors ſo long as they continue their ſubſcription. Each governor for life has the privilege of relieving eight patients in a year, and of having two of them on the books at a time. Subſcribers of five guineas may relieve five patients, and thoſe who ſubſcribe three guineas may relieve two patients. A double ſubſcription acquires a double privilege. The affairs of the hoſpital are conducted by a committee of 24, of whom the treaſurer is one, who meet at the hoſpital every Wedneſday. Four of them preſide, by rotation, for two ſucceſſive months, at the public baptiſms; and at the Midſummer court ſix retire, and ſix are elected to ſupply their places. The officers, beſides the preſident, vice-preſidents, and treaſurer, are a preacher and a chaplain, four phyſicians, two of whom practiſe more particularly in midwifery, a ſurgeon, an apothecary, a ſecretary, and a matron, who is a ſkilful midwife, and reſides in the houſe, ſuperintending the nurſes and ſervants, and the whole domeſtic economy. The property of this hoſpital conſiſts, beſides its leaſehold premiſes, of 11,000*l.* three per cent. conſol. bank annuities, and 10,000*l.* reduced annuities, and two annuities of 5*l.* and another, during the life of the duke of York, of 25*l.* The whole annual expenditure amounts in general to about 1500*l.* ſupplied by the dividends on its capital, legacies, ſubſcriptions, and collections at the chapel, and at the anniverſary meeting. Pupils are allowed to be received who pay to the charity for their lodging and board during their ſtay in the hoſpital, beſides ſome fees to the matron and medical officers. The preſent building, at the entrance of the City-road, was begun in October, 1770, and completed at an eſtimated charge of 3500*l.* ſo as to be open for the reception of patients in April, 1773. It was licenſed for the public reception of pregnant women, purſuant to an act of parliament, paſſed in the 13th year of the reign of George III. (13 Geo. III. c. 82.) This hoſpital, which in 1809 had ſubſiſted 59 years, has relieved, in that time, 24,902 poor married women, of whom 25,196 children have been born. During the year, ending Lady-day, 1809, their number was 413, and the male children born were 227, and the females 186. Out of the whole number, 292 women have been delivered of twins, and two women had three children at the birth.

The Weſtminſter new lying-in hoſpital, on the Surrey ſide of Weſtminſter-bridge, was inſtituted by ſubſcription in the year 1765. It is governed by a preſident, four vice-preſidents, a treaſurer, and a committee of governors. The qualifications of governors are various. An annual ſubſcription of three guineas entitles to recommend three in-patients, three out-patients at their own habitations, and any number for advice, and to vote at elections. An annual ſubſcription of five guineas entitles to recommend five in-patients, five at their own habitations, and any number for advice, with a vote at elections, &c. A ſubſcription of 30 guineas conſtitutes a governor for life, entitled to recommend yearly three in-patients, three at their own habitations, and any number for advice, and to vote at elections, &c. The privilege of recommending patients is extended in proportion to the ſubſcription. There are four quarterly meetings at the hoſpital in the year; and a weekly board, conſiſting of any number of the committee annually appointed in January, is held at the hoſpital every Tueſday, for the general affairs of the inſtitution. The phyſicians practiſing midwifery are allowed to take pupils, two of whom may reſide in the houſe for three months, and board for a ſtipulated price, at the matron's table: female pupils are alſo allowed upon the ſame terms. One of the phyſicians attends at the hoſpital every Tueſday and Friday, from 11 till 12 o'clock, to give advice in the ſeveral diſorders incident to child-bearing and infancy. It is attended by two phyſicians and accoucheurs, a phyſician extraordinary, an apothecary, and a ſurgeon. The officers are a ſecretary, chaplain, and matron or midwife, conſtantly reſident in the hoſpital, ſuperintending the nurſes and ſervants, &c.

In connection with lying-in hoſpitals, we may mention two or three inſtitutions for the purpoſe of delivering poor married women at their own habitations. An uſeful inſtitution of this kind dates its riſe in the year 1757, and is under the direction of a preſident, ſix vice-preſidents, a treaſurer, ſecretary, and governors. An annual ſubſcription of one guinea, or more, or a benefaction of 10 guineas or upwards, conſtitutes a governor. An annual governor for one guinea may recommend eight objects within the year, and in proportion for a larger ſum, and the governor for life recommends the ſame number annually. This inſtitution is under the direction of a preſident, ſix vice-preſidents, a treaſurer, a conſulting phyſician, three phyſicians and accoucheurs. The ſubordinate officers are a ſecretary and collector. The midwives are 27 in number, who reſide in all parts of the town. During the firſt 50 years of this ſociety the deliveries amounted to 178,983; and in the year 1808 to 4100. Another inſtitution of the ſame kind, called the "Benevolent inſtitution, for the ſole purpoſe of delivering poor married women at their own habitations," was eſtabliſhed in January, 1780. It is ſupported and conducted on a plan ſimilar to that of the inſtitution laſt mentioned. The officers are a preſident, ſeven vice-preſidents, a treaſurer, a phyſician, ſecretary, and 40 midwives. Another ſociety of a like kind was formed at Tottenham, near London, in Auguſt, 1791.

Hospital, *Magdalen*, in St. George's Fields, was inſtituted in the year 1758, for the relief and reformation of proſtitutes. The queen is patroneſs of this charity; it is under the direction of a preſident, ſix vice-preſidents, treaſurer, and committee of 32 governors. It is attended by a phyſician, two ſurgeons, and two apothecaries. The domeſtic officers are a chaplain, ſteward, ſecretary, matron and aſſiſtant, and meſſenger and aſſiſtant. Twenty guineas conſtitute a governor for life, and an annual ſubſcription of five guineas is a qualification for a governor for one year, which ſubſcription, when it amounts to 25 guineas, qualifies a governor for life. Four general courts are held in every year; and at the general court in April, the committee, and all officers, except the preſident, are elected. The committee, conſiſting of 32 governors, meet at the hoſpital every Thurſday; and two of them, in rotation, attend at the chapel every Sunday at morning and evening ſervice, when a collection is made previouſly to admiſſion. This hoſpital was firſt eſtabliſhed in Preſcott-ſtreet, Goodman's-fields; and the new building in Blackfriars' road, St. George's-fields, was opened in the year 1758. An act of incorporation was granted by parliament in 1769. The new hoſpital is calculated to receive about 80 penitents every year; and during the period of its ſubſiſtence more than two-thirds of the women who have been admitted have been reconciled to their friends, or placed in honeſt employments or reputable ſervices. A very conſiderable number have been married, and have become reſpectable members of ſociety; but ſome, as might naturally be expected, have relapſed into their former errors. A probationary ward has been inſtituted for the young women on their firſt admiſſion; a ſeparation of thoſe of different deſcriptions and qualifications has been eſtabliſhed; and apartments have been fitted up in the lodge for the reſidence of the chaplain and his family, that he may with the greater facility continue to devote his time and attention to the inſtruction of the women. Each claſs is entruſted to its particular aſſiſtant, and the whole is under the inſpection of the matron. It appears by a ſtatement, extracted from the books of the hoſpital, that from the 10th of Auguſt, 1758, to the 7th of January, 1808, 3865 women have been admitted, and that of theſe 2532 have been reconciled to their friends, or placed in ſtations of reputable ſervice or employment; 102 have been lunatic, or troubled with fits or incurable diſorders; 72 have died; 573 have been diſcharged at their own requeſt; and 506 diſcharged for improper behaviour.

An inſtitution, in aid of the Magdalen hoſpital, was founded in the year 1807, under the appellation of the "Female Penitentiary," the external management of which was confided to a committee of 24 gentlemen, together with a treaſurer, a ſecretary, and aſſiſtant; and the interior to a committee of 24 married ladies. The eſtabliſhment was fixed at Cumming-houſe, Pentonville, Iſlington, by the purchaſe of a long leaſe of the houſe and adjoining ground, to which has been ſince added a contiguous building for a temporary infirmary. The penitentiary-houſe is divided into ſix apartments; a temporary ward for caſes of emergency, two probationary wards, wards for perſons fully admitted after probation, a ward for diſeaſed ſubjects, a ſick ward, and a refractory ward: a part of the houſe is appropriated to divine ſervice. This inſtitution is attended gratis by a phyſician, ſurgeon, and apothecary. The matron reſides in the houſe.

Hospital, *St. Peter's*, at *Newington Butts*, was erected by the company of Fiſhmongers, by virtue of letters patent of king James I. in 1618, for the reception of divers of their poor members, who had penſions bequeathed them by the wills of ſome of their company.

Hospital, *Royal*, for diſabled ſoldiers, commonly called *Chelſea-College*.

The building was originally begun by king James I., in the 5th year of his reign, for a college to conſiſt of a number of learned divines, who, being furniſhed with books and all means of ſubſiſtence, might devote their time to the ſtudy and teaching of controverſial divinity, eſpecially thoſe points in diſpute between the churches of England and Rome. Accordingly he incorporated a provoſt and fellows, by the title of king James's college, in Chelſea. The corporation was endowed by his letters patent, with the reverſion of certain lands in Chelſea, and authorized alſo to receive of his loving ſubjects lands not exceeding, in the whole, the yearly value of 3000*l.* Every thing being previouſly ſettled, king James laid the firſt ſtone of the intended college; but for want of money the building went on ſlowly; and, at length, before an eighth part of the model was executed, it ſtood ſtill. In this ſtate it remained for ſeveral years: but in the year 1616 the king ſent letters to the archbiſhop of Canterbury, requiring him to ſtir up the clergy in his province to contribute towards it; in conſequence of which collections were made in ſeveral pariſhes of England, but their produce was ſmall, and was ſwallowed by the fees and collectors. The corporation, however, though the building was ſtopped, was nominally kept up during the life of king James I. The troubles under king Charles I. occaſioned all thoughts of completing the work to be laid aſide. After the reſtoration, king Charles II. erecting a convenient hoſpital for the reception of ſick, maimed, and ſuperannuated ſoldiers, converted the unfiniſhed buildings of this college to that uſe; whence the hoſpital has retained the title of the "College." It was founded by king Charles II., carried on by king James II., and finiſhed in the reign of king William and queen Mary, by ſir Chriſtopher Wren. The whole expence of this ſtructure amounted, as it is ſaid, to 150,000*l.*, and the extent of the ground is above forty acres.

The building is very ſpacious and magnificent: its figure is a Π; the middle or front part whereof conſiſts of a chapel and hall; the other two lines, being four ſtories high, are divided into wards or galleries, two in each ſtory; containing each twenty-ſix diſtinct apartments for the foot ſoldiers. At each of the four corners of the main building, there is a pavilion, in one whereof is the governor's lodging, and the council-chamber; the other being lodgings for ſeveral of the officers of the houſe. Beſide the main building, there are four wings or out-buildings; one for the infirmary, another for ſeveral officers of the houſe, another for old maimed officers of horſe and foot; and the fourth for the baker, laundreſs, &c. The number of penſioners in the houſe is, in general, eſtimated at about 400, beſides the officers and ſervants in the houſe: the out, or extraordinary penſioners, are alſo very numerous; and theſe, upon occaſion, do duty in the ſeveral garriſons, from whence draughts are made for the army, &c. Their allowance is 7*l.* 12*s.* 6*d.* a year each.

The penſioners are all provided with cloaths, diet, waſhing, lodging, and firing; and have a weekly allowance of 8*d.* for their pocket-money.

The qualifications required to be admitted of this body, are, that the candidate bring a certificate from his ſuperior officer that he has been maimed or diſabled in the ſervice of the crown; or that he has ſerved the crown twenty years, which muſt be made appear by muſter-rolls.

To defray the charges of this hoſpital, there is a conſiderable ſum paid yearly out of the poundage of the army; beſide one day's pay of each officer, and each common ſoldier, every year, which, in time of war, amounts to a very conſiderable ſum. In caſe of a deficiency, it is ſupplied by parliament.

For the adminiſtration of this hoſpital there are commiſſioners, a governor, whoſe ſalary is 500*l.* *per annum*, a lieutenant-governor with 400*l.*, a major with 270*l.*, an adjutant with 100*l.*, two chaplains with 100*l.* a-year each, a phyſician and ſurgeon, whoſe ſalaries are 100*l.* a-year each, beſides ſurgeon's mates and apothecary, a treaſurer, who is the paymaſter-general of the land-forces for the time being; and his deputy and clerk, ſecretary and regiſter and clerks, agent and pay-maſter to the out-penſioners and his clerks, comptroller, ſteward, houſe-keeper, organiſt, clerk of the works, &c. &c.

Hospital, or *Corporation*, *Scots*, a charitable inſtitution which commenced in 1665 by the voluntary aſſociation of reſpectable merchants, tradeſmen and others, and which obtained a charter of incorporation by letters patent under the great ſeal of England, bearing date the 30th of June 1665. By theſe, the perſons deſcribed in the charter were empowered to erect an hoſpital in the city and liberty of Weſtminſter, for the maintenance of old or decayed artificers of the Scottiſh nation, and for training up their children to handicraft employments. In 1673 this corporation was enabled to erect a hall, with ſix adjoining tenements, for fulfilling the purpoſe of the charity, in Blackfriars. Afterwards it became neceſſary to apply to the crown for an enlargement of the numbers, powers, and privileges of the corporation. Accordingly new letters patent were iſſued, bearing date the 16th of November, 1676, by which 33 aſſiſtants were added to the former eight governors; liberty was granted to eſtabliſh their hoſpital either in London or Weſtminſter; and they were empowered to purchaſe and to hold lands to the yearly value of 500*l.*, by the name and ſtyle of "The Maſter, Governors, and Aſſiſtants of the Scottiſh Hoſpital, of the Foundation of king Charles II." The deſign of an hoſpital, however, was afterwards abandoned; and in its place was ſubſtituted the wiſer mode of aſſiſting and relieving the poor objects at their own habitations. The charter of 1676 having been found inſufficient by its proviſions to render the inſtitution ſufficiently extenſive in its beneficial effect, application was made to his preſent majeſty for a new charter of incorporation, which was obtained, bearing date the 28th of November, 1775; by which the corporation is re-eſtabliſhed under the ancient name and ſtyle of "The Scottiſh Hoſpital of the Foundation of Charles II.;" and the government veſted in a preſident, ſix vice-preſidents and a treaſurer, to be elected annually on St. Andrew's day, or the day after, and the number of governors left unlimited. A committee is alſo choſen on the ſame day, conſiſting of 20 governors, beſide the preſident, vice-preſidents, and treaſurer, who are of the committee, for conducting the affairs of the corporation. The officers of the ſociety are a chaplain and ſecretary. By the charter there muſt be five general courts held every year; and the committee meet on the ſecond Wedneſday in every month, at the hall of the corporation in Crane-court, Fleet-ſtreet, to receive the petitions of the patients recommended by the governors, and in order to diſtribute the charity. A donation of 10 guineas conſtitutes a governor for life; and a ſubſcription of one guinea or upwards, annually, qualifies to be an annual governor. In conformity to a bye-law, it is the practice, in order to form a capital, to inveſt, in ſome one of the public funds, one-half of every donation of 10 guineas and upwards to 20, and the whole of every donation of this laſt amount, or beyond it. The annual ſubſcriptions, and a moiety of the lower donations, are applied towards the regular monthly expenditure. Every governor, whether annual or for life, has the privilege of recommending one, and only one, diſtreſſed object for relief. This inſtitution may be juſtly denominated an "Hoſpital of Out-Patients;" the objects of it being ſupported and relieved by weekly, monthly, or quarterly allowances in money, and with medical aſſiſtance and advice at their own habitations; and ſuch of them as are deſirous of returning to their native country for the benefit of their health, or to ſpend the remainder of their days with their relations and friends, have their paſſages by ſea paid, and money advanced to ſupply their immediate wants, by which they have not only the benefit of an hoſpital and work-houſe, without the diſagreeable circumſtances attending them, but all the comforts of their families and friends reſerved for them.

The number of poor, lame, and ſickly perſons relieved, and paſſages to Scotland paid for, by the hoſpital, annually for five years, have been as follows:

For the year	1803	to St. Andrew's day	-	1418
For ———	1804	- to do.	-	- 1598
For ———	1805	- to do.	-	- 1258
For ———	1806	- to do.	-	- 1610
For ———	1807	- to do.	-	- 1602

Hospital, *Small-Pox*, or hoſpital for relieving poor people afflicted with the ſmall-pox and for inoculation, was inſtituted by voluntary ſubſcription in the year 1746. The object met with very general encouragement, and ſeveral houſes remotely ſituated from one another, were engaged in ſubſerviency to the deſign. This hoſpital afterwards conſiſted of two houſes, at a due diſtance from each other, in airy ſituations. A houſe for preparing patients for inoculation was erected at Pancras, and that for receiving them when the diſeaſe appears, and for accommodating patients who have it in the natural way, was then in Cold-bath fields. The new building at Battle-bridge St. Pancras, was finiſhed and opened at Michaelmas 1767, for the reception of patients before inoculation. The whole expence of the building, and its accidental charges, amounted to 8955*l.* 19*s.* 1*d.* In December 1767 there were 300 patients for inoculation in the hoſpital. The hoſpital in Cold-bath fields requiring a general repair, and the governors being poſſeſſed of freehold ground at Pancras, on which the inoculation hoſpital ſtood, and where they had ſufficient room for a new building, determined to erect a new edifice in the room of the other, which needed repair. Accordingly in

1792 a plan was obtained, and a ſpecial committee was appointed to conduct the buſineſs. It was actually begun in May 1793, and completely finiſhed in June 1794, and the patients were removed into it in under the direction of the medical officers. The whole ſubſcription for this purpoſe amounted to 3971*l.* 18*s.* 8*d.*; and the building charges amounted to 761*l.* 3*s.* 2*d.* beyond that ſum. A new ſet of rules was framed, and one apothecary and one matron were conſtituted to take the direction of both houſes, under the ſuperintendance of the phyſician. Soon after the practice of vaccination became prevalent, Dr. Woodville, phyſician of the hoſpital, firſt introduced it Jan. 21ſt, 1799, and adopted it very generally during the following year, thus greatly aſſiſting Dr. Jenner in his reſearches and experiments; and in the ſpace of three years from that time, 9000 were vaccinated, without any complaint of unſucceſsful practice. In 1801, their number increaſed to 11,800, of whom 2500 were afterwards teſted by variolous inoculation; and the progreſs was ſo rapid that 4290 were vaccinated in 11 months. In 1802 the number of vaccinated patients had increaſed to 13,715; and no failure of ſucceſs appeared. After this time the new practice ſeems to have declined in reputation, for in the following year only 2802 were vaccinated at the hoſpital. In 1806, Dr. Adams having ſucceeded the deceaſed Dr. Woodville in the office of phyſician, vaccination was ſlowly recovering from its depreſſion, and from the monthly tables of the hoſpital in 1805 it appeared, that the in and out-patients vaccinated amounted to 2096, and thoſe of variolous inoculation to 2638. In 1807 vaccination further declined; but there was no fatality in the hoſpital in the natural diſeaſe during five months. From the report communicated by Dr. Adams to the college of phyſicians, it appears, that 20,324 had been vaccinated by the inſtitution ſince its commencement in 1799, of whom only 18 had afterwards taken the ſmall-pox caſually; and that three years were the critical period at which the greater part of them had taken it. The prejudice, however, againſt vaccination prevailed. During the year 1808, the patients relieved in the caſual ſmall-pox amounted to 132, thoſe for inoculation to 1296, and thoſe of vaccination to 1252; and the total number of theſe, ſince 1799, amounted to 23,197; of caſual patients, ſince the firſt eſtabliſhment, 21,868, and of variolated patients to 47,471; making together 92,536. Dr. Lettſom ſtates, in favour of vaccination, that not more than four have died in 60 thouſand vaccinated patients. (See Cow-*pox.*)

This ſociety is ſupported without charter by voluntary contribution; their property conſiſts of the freehold eſtate at Pancras, containing four acres of land; 8000*l.* in reduced bank annuities, and 9000*l.* conſols, and 38*l.* 7*s.* 2*d.* imperial annuities. The receipts generally amount to about 1400*l.* per annum, and the expences generally exceed that ſum. The king is the patron of this hoſpital; and the eſtabliſhment is governed and conducted by a preſident, ſix vice-preſidents, a treaſurer, phyſician, ſecretary, reſident ſurgeon and apothecary, and matron, a houſe committee of 13 governors, and a committee of ſeven auditors, choſen annually. Thirty guineas conſtitute a governor, and five guineas an annual ſubſcriber; and any double ſubſcription gives a double privilege. Smaller ſums are gratefully received, but give no privilege. Every governor may recommend one patient into each houſe at a time. Two half-yearly courts are held before Midſummer and Chriſtmas. The houſe-committee of 13 meet on the firſt Thurſday in every month to manage the whole concerns of the inſtitution. The phyſician preſcribes, inoculates, and takes the general overſight and direction of the family; the ſecretary receives legacies, donations, ſubſcriptions, &c. and keeps all the accounts and minutes, &c.; the apothecary, who is alſo a ſteward, is reſident at the hoſpital, and keeps an accurate regiſter of the medical tranſactions, aſſiſts the matron reſpecting the proviſions and houſhold direction, and attends all the committees; the matron's office comprehends every thing which is commonly included in that of miſtreſs of a family. No officer can receive any fee on pain of diſmiſſion. Both hoſpitals are plain brick buildings, that for inoculation and the other for the natural ſmall-pox, being contiguous, but entirely diſtinct from one another, and communicating only by a covered paſſage. The airineſs of the ſituation, and the cleanlineſs which is preſerved through both hoſpitals, and the good order maintained by the vigilance of the reſident ſurgeon and the aſſiduous attention of the matron, render theſe hoſpitals well deſerving the notice of every friend to humanity.

Hospital, *Sutton's*. See Chartreuse.

Hospital, *St. Thomas's*, in Southwark, is eſtabliſhed for the ſame purpoſes as that of St. Bartholomew.

It was originally founded an hoſpital by Richard, prior of Bermondſey in 1213, and ſurrendered to king Henry VIII. in 1538; in the year 1551, the mayor and citizens of London, having purchaſed of king Edward VI. the manor of Southwark, including this hoſpital, repaired and enlarged it, and admitted into it 260 poor, ſick and helpleſs objects; upon which the king, in 1553, incorporated it together with thoſe of Chriſt, Bridewell, Bethlem, and St. Bartholomew. This ancient ſtructure, much damaged by time and by fire, was rebuilt by voluntary ſubſcription in the year 1693; and by additional buildings greatly enlarged; in conſequence of which it conſiſted of three beautiful ſquares; to which the governors, in 1732, added a magnificent new building, conſiſting of ſeveral wards, a brew-houſe, and other neceſſary offices, at their own expence. It now conſiſts of four quadrangular courts; in the firſt are wards for women; in the ſecond two chapels, the leſſer for the private uſe of the hoſpital, and the larger parochial; in the ſame court and adjoining to it, are the houſes of the treaſurer, and other officers; in the third court are ſeveral wards for men; the fourth hath alſo wards, hot and cold baths, a ſurgery, theatre, apothecary's ſhop, &c. The number of in and out patients relieved by this hoſpital, at an average of ſix or ſeven years, may be ſtated at 9000, at an expenditure of about 10,000*l.* Thoſe of the laſt year appear by the report of 1811 to have been 8318. The governors of this hoſpital are the lord mayor and court of aldermen, and the number of others, who, on receiving a governor's ſtaff, give a benefaction of 50*l.* or upwards, is unlimited; but it is commonly between four and five hundred. They chooſe their officers and ſervants, who are; a preſident, treaſurer, hoſpitaller or chaplain, beſides the miniſter of the pariſh, who is paid by the hoſpital, three phyſicians, three ſurgeons, apothecary, clerk, receiver, ſteward, matron, butler, and brewer, baker, cook, aſſiſtant and ſervant, an aſſiſtant clerk in the compting-houſe, two porters, four beadles, nineteen ſiſters, nineteen nurſes, nineteen watch-women, a chapel-clerk and ſexton, and one watchman. The houſe contains eighteen wards, and about 485 beds.

Hospital, *Weſtminſter*, or *Public Infirmary*, was inſtituted in the year 1719, at the expence, and by the contribution of ſeveral benevolent individuals, "for the relief of the ſick and needy from all parts." The patient is admitted by a recommendation ſigned by any governor, caſes of accident excepted, which are admitted without recommendation at all hours of the day or night; and ſeveral beds are reſerved for them. A benefaction of 30*l.* or upwards, or of three guineas or more per annum, qualifies the donor to become a truſtee. A board of truſtees meets every Wedneſday morning to tranſact the affairs of the charity; and four quarterly general boards are held for the ſuperviſion of its concerns. The capital of this hoſpital conſiſts in ſeveral funds of 11,500*l.* 15*s.* 4*d.* three per cents. The inalienable capital for the incurables amounts to 21,368*l.* 18*s.* 1*d.* in ſeveral funds of three per cent., and the maintenance, cloathing, and medicines are charged at 20*s.* per week, which does not exhauſt more than one-third of the income appropriated for them. The queen is the patroneſs of this hoſpital; and it is under the direction of a preſident, nine vice-preſidents, a treaſurer, a ſecretary and receiver, three phyſicians, three ſurgeons, and an aſſiſtant ſurgeon.

Beſides the hoſpitals already enumerated, there are royal hoſpitals, ſuch as that at Haſlar, near Portſmouth, for ſick and hurt ſeamen and marines, and the royal hoſpital at Plymouth, and many others, ſupported by the benefactions of private and voluntary contributors, which provide relief for almoſt every ſpecies of diſeaſe or injury. For a particular account of all hoſpitals in London, and all public charities and benevolent eſtabliſhments, for the relief and inſtruction of the poor; ſee a work, the reſult of much inveſtigation and labour, and written with the moſt laudable deſign by A. Highmore, eſq. 1809; entitled, "Pietas Londinenſis; or the Hiſtory, Deſign, and Preſent State of the various Public Charities in and near London."

Hospitals, *Camp,* are either general or regimental.

The general hoſpitals are of two kinds, *viz.* the *flying* hoſpital, attending the camp at ſome convenient diſtance, and the *ſtationary* hoſpital, which is fixed to one place. In the choice of both, it will be better to have them in towns than villages, as the former will afford larger wards, beſides more of other conveniences; theſe wards ſhould be as airy as poſſible.

As to the diſpoſition of hoſpitals, in regard to preſerving the purity of the air, the beſt rule is to admit but few patients into each ward. It will alſo be found a good expedient, when the cielings are low, to remove ſome part of them, and to open the garret-ſtory. The doors and windows may likewiſe be opened, and ventilators uſed to purify the air of every ward. In winter-hoſpitals, the wards are to be warmed with chimnies, and never by ſtoves; for though the latter may warm a large ward better, and at a leſs expence, yet by ſcarce making any draught of air, they will be apt to increaſe its putrid quality; whereas a fire, kept up in a chimney, acts like a conſtant ventilator.

The *general* hoſpital ſhould receive only ſuch ſick as the regimental ones cannot conveniently contain, together with thoſe who cannot be removed with the army. Without this diſperſion of the ſick, the general hoſpital, in bad ſeaſons, would have a greater number than could be well attended; and what is equally, if not more pernicious, it would be too much crowded, by which means the contagion would ſpread, and the mortality be rendered more general.

Regimental hoſpitals are of the greateſt importance, and therefore ſhould be ſupplied with blankets and medicines from the public ſtores, with an allowance alſo for nurſes and other neceſſaries. Nor are they to be maintained in the field only, but alſo in winter-quarters, as there will always be a great many more ſick than can be taken care of in the general hoſpital.

Barns, ſtables, granaries, and other out-houſes, but above all, churches, make the beſt hoſpitals, from the beginning of June to October; for as the greateſt danger ariſes from foul air, which cannot be compenſated by diet or medicine, we may lay it down as a rule, that the more airy and large the hoſpitals are, the leſs danger there is of the ſickneſs ſpreading. Pringle Obſerv. on the Diſeaſes of the Army, p. 104, ſeq.

Hospital, *Fever*, in *Medicine.* See Fever and Typhus.

Hospital *Ship.* See Ship.

Hospital, in *Geography*, an iſland in the river St. Lawrence, Upper Canada, in front of the townſhip of Edwardſburgh, containing about 100 acres.

HOSPITALER, one that entertains and provides for poor people, travellers, &c.

The appellation is chiefly given to certain communities of religious; as, the hoſpitalers of Elſefort in Eſſex, inſtituted to take care of lepers; hoſpitalers of St. John Baptiſt, of Coventry; hoſpitalers of St. Julian; hoſpitalers of St. Leonard, at York, &c.

The religious hoſpitalers generally follow the rule of St. Auguſtine. Moſt of them pretend, that St. Martha was their firſt foundreſs, and choſe her for their patron, becauſe ſhe entertained Jeſus Chriſt at her houſe. Some of them go back to the patriarch Abraham for their founder.

There are alſo hoſpitalers among the military orders; ſuch as the knights of St. Lazarus, and St. John of Jeruſalem.

Hospitalers, *Hoſpitalarii*, more particularly denote an order of religious knights, who built an hoſpital at Jeruſalem, wherein pilgrims were received. To theſe pope Clement V. transferred the effects and revenues of the Templars; whom, by a council held at Vienne, he ſuppreſſed, for their many and great miſdemeanors.

Theſe hoſpitalers were otherwiſe called *Knights of St. John of Jeruſalem;* and are the ſame with thoſe whom we now call the *Knights of Malta.*

Hospitaler, in *Mythology*, is a name which the ancient Romans gave to Jupiter, calling him Jupiter Hoſpes, becauſe they conſidered him as the guardian of hoſpitality.

HOSPITIUM, Inn; a term peculiarly uſed, in our law-books, for an inn of court.

Hospitium is alſo uſed for a little convent, which the religious built for the reception of ſtrangers and travellers of the ſame order, who had occaſion to ſtay with them ſome time.

Moſt of theſe hoſpitia, or inns, in time became fixed convents.

In the middle ages there ſeem to have been no inns or houſes of entertainment for the reception of travellers; and this circumſtance affords a proof that little intercourſe ſubſiſted between different nations. And as hoſpitality is a virtue of the firſt rank among people whoſe manners are ſimple, and who are ſeldom viſited by ſtrangers, it was conſidered at the period to which we now refer as a very important and indiſpenſible virtue; and not as one of thoſe virtues which men may practiſe or not, according to the temper of their minds, and the generoſity of their hearts. Hoſpitality was enforced by ſtatutes, and thoſe who neglected this duty were liable to puniſhment. "Quicumque hoſpiti venienti lectum, aut focum negaverit, trium ſolidorum in latione mulctetur, Leg. Burgund. tit. 58. § 1. Si quis homini aliquo pergenti in itinere manſionem vetaverit ſexaginta ſolidos componet in publico." Capitul. l. vi. § 82. The laws of the Slavi were ſtill more rigorous; they ordained "that the moveables of an inhoſpitable perſon ſhould be confiſcated, and his houſe burnt." They were even ſo ſolicitous for the entertainment of ſtrangers, that they permitted the landlord to ſteal for the ſupport of his gueſt. "Quod noctu furatus fueris, cras appone, hoſpitibus." Rerum Meclcburg, l. viii. a Mat. Jo. Beehr. Lipſ. 1751, p. 50. In conſequence of theſe laws, or of that ſtate of ſociety which made it proper to enact them, hoſpitality abounded while the intercourſe among men was inconſiderable, and ſecured the ſtranger a kind reception under every roof where he choſe to take ſhelter. As the intercourſe among men increaſed, that which was a pleaſure became a burden, and the entertaining of travellers was converted into a branch of commerce.

Hospitium was likewiſe formerly uſed for procuration, or viſitation money. See Procuration.

HOSPODAR, the title borne by the prince of Walachia and Moldavia.

The Hoſpodars of Walachia and Moldavia receive the inveſtiture of thoſe principalities from the grand ſeignior, by a veſt, and a ſtandard which he gives them.

They are ſometimes depoſed by him; though in other reſpects they have ſovereign power within their ſtates.

HOSSAINPORUM, in *Geography*, a principal town of Cotwally, in Bengal; 50 miles N. of Moorſhedabad. N. lat. 24° 57′. E. long. 88° 7′.

HOSSAINPOUR, a town of Hindooſtan, in Oude; 40 miles N.N.E. of Manickpour.

HOSSAMALLY, a town of Hindooſtan, in Guzerat; 25 miles S. of Amedabad.

HOSSAREE, a town of Hindooſtan, in Canara; 10 miles E.N.E. of Barcelore.

HOSSEFIN, or Longrosson, a town of Arabia, in the province of Oman, on the E. coaſt; 30 miles N.N.W. of Sohâr. N. lat. 24° 40′.

HOST, Hospes, which ſome will have thus called, *quaſi hoſtium*, or *oſtium petens*; for *oſtium* was anciently written with an aſpirate; a term of mutual relation applied both to a perſon who lodges and entertains another, and to the perſon thus lodged, &c.

Thus the innkeeper ſays, he has a good hoſt, in ſpeaking of the traveller who lodges with him; and the traveller again ſays, he has a kind hoſt, in ſpeaking of his landlord. It muſt be obſerved, then, that it was the cuſtom among the ancients, when any ſtranger aſked for lodgings, for the maſter of the houſe, and the ſtranger, each of them to ſet a foot on each ſide of the threſhold, and ſwear they would neither of them do any harm to the other. It was this ceremony that raiſed ſo much horror againſt thoſe who violated the law or right of hoſpitality on either ſide; inaſmuch as they were looked on as perjured. Inſtead of hoſpes the ancient Latins called it *hoſtis*, as Cicero himſelf informs us; though, in courſe of time, *hoſtis* came to ſignify an *enemy*; ſo much was the notion of hoſpitality altered.

Host is alſo uſed by way of abbreviation for *hoſtia*, a victim, or ſacrifice, offered to the Deity.

In this ſenſe, hoſt is more immediately underſtood of the perſon of the word incarnate, who was offered up a hoſt, or *hoſtia*, to the Father on the croſs, for the ſins of mankind.

Host, or *Hoaſt*, is chiefly uſed, in the Romiſh church, for the body of Jeſus Chriſt, contained under the ſpecies of bread and wine, which is offered up every day, a new hoſt, or ſacrifice in the maſs.

Pope Gregory IX. firſt decreed a bell to be rung, as the ſignal for the people to betake themſelves to the adoration of the hoſt.

The veſſels wherein the hoſts are kept is called the *cibory*; being a large kind of covered chalice.

HOSTAGE, formed of *hoſt*, and that of *hoſpes*, a perſon left as ſurety for the performance of the articles of a treaty.

When two enemies are on the point of concluding a treaty, or capitulation, it is frequent for them to give hoſtages on each ſide, as ſureties for the execution of what is contained therein.

An hoſtage is either a principal, or an acceſſary, according to the ſtate of the caſe. He is only an acceſſary, when, for inſtance, a prince promiſes fidelity to another, and gives up his ſon, or ſome other great lord, to aſſure his engagement, without any farther ſtipulation. For here, if the prince fail of his word, the hoſtage is no ways accountable for it.

But the hoſtage becomes a principal, when it is expreſsly ſtipulated, that he ſhall be anſwerable for the event: for inſtance, if a city engage to ſurrender, in caſe it be not relieved in ſo many days, and to ſecure the engagement, give hoſtages, theſe hoſtages are what a ſurety is to a creditor for the debt of his principal. So that if the relief do not come, and yet the citizens refuſe to ſurrender, the hoſtages ſtand in their places, become principals, and are liable to be puniſhed for the prevarication of thoſe they are become ſureties for.

A hoſtage given for another perſon becomes free when that perſon dies.

HOSTANA, in *Geography*, a town of Iſtria; 6 miles N. of Rovigno.

HOSTAUN, a town of Bohemia, in the circle of Pilſen; 9 miles N.W. of Teinitz.

HOSTE, or l'Hoste, John, in *Biography*, who flouriſhed in the former part of the ſeventeenth century, was born at Nancy, in Lorrain. He was ſome time profeſſor of civil and canon law in the univerſity of Pont-à-Mouſſon; and afterwards occupied the mathematical chair. His talents and induſtry recommended him to the notice and favour of Henry, duke of Lorrain, who appointed him to the poſts of intendant of fortifications, principal engineer, and counſellor of war. He was author of many valuable works connected with his profeſſion, of which the following are the principal: "Le Sommaire et l'Uſage de la Sphere Artificielle:" "Deſcription et Uſage des principaux Inſtrumens de Geometrie:" "Du Cadran et Quarrè." He died in the year 1631. Moreri.

Hoste, or l'Hoste, Paul, was born at Pont-de-Veal, in France, in the year 1652. He entered into the order of the Jeſuits in 1669, and afterwards took ſeveral voyages with the marſhals D'Eſtrèes and De Tourville, and the duke de Mortemart, whom he accompanied, for twelve years, in their naval expeditions. He diſtinguiſhed himſelf by his great ſkill in mathematics, and became profeſſor of thoſe ſciences at Toulon, where he died in 1709. He was author of 1. "Traitès des Evolutions Navales," folio, 1697. 2. "Traitès de Mathematique les plus neceſſaire à un Officier," 3 toms. 12mo. The treatiſe on naval evolutions was enlarged and reprinted in 1727; it is hiſtorical as well as didactic, and contains an account of the principal naval tranſactions during fifty years preceding the time of its firſt publication, illuſtrated with four hundred copper-plate engravings. Annexed to it is a treatiſe "On the Conſtruction of Ships." Moreri.

HOSTEA, in *Botany*, was ſo called by profeſſor Willdenow, in compliment to the highly meritorious Dr. Nicholas Thomas Hoſt, author of a *Synopſis Plantarum in Auſtria creſcentium*, octavo; and of a moſt ſuperb work in three volumes, folio, with coloured plates in the ſtyle of Jacquin's publications, entitled *Gramina Auſtriaca*. Profeſſor Jacquin has called a plant *Hoſta*, with the ſame intention, in his *Hortus Schoenbrunnenſis*, v. 1. 60. t. 114, which appeats to us the *Cornutia pyramidata* of Linnæus, notwithſtanding the doubts and objections of Jacquin, and the diſagreement of its fruit with the deſcriptions of Plumier and Linnæus, which laſt ſeem to us erroneous. (See Cornutia.) The fruit of the Linnæan ſpecimens at leaſt exactly agrees with Jacquin's figure, as to the number of cells and ſeeds. The *Hoſtea* of Willdenow, *Sp. Pl.* v. 1. 1274, is however the *Matelea* of Aublet, *Guian.* v. 1. 277. t. 109, under which appellation it is deſcibed by Mr. Brown in his *Aſclepiadeæ*, 25; and though this name has received no explanation, and appears to be barbarous, it is ſufficiently harmonious, and in compliance with a writer who has treated his ſubject ſo well as Mr. Brown, may perhaps be admiſſible. See Matelea.

HOSTEL, or Hotel, a French term, anciently ſignifying a houſe or dwelling-place.

It is now more commonly uſed for the palaces or houſes of the king, princes, and great lords.

In this ſenſe they ſay, the *hotel de Condé*, *hotel de Conti*, *hotel de Louvre*, &c.

The grand prevot de l'hotel was the firſt judge of the officers of the king's houſhold, his juriſdiction was much like that of lord-ſteward of the houſhold of the king of England.

The *hotel de ville* is what we call a *town-houſe*, or *town-hall*. *Hotel-dieu*, is a common name for the chief hoſpital for the reception of ſick perſons, in moſt of the cities of France. *The Hotel de Mars* is a hoſpital near Paris; of the ſame nature with Chelſea hoſpital.

HOSTEREN, in *Geography*, a ſmall iſland in the N. ſea, near the coaſt of Norway. N. lat. 60°.

HOSTERLITZ, a town of Moravia, in the circle of Znaym; 12 miles N.E. of Znaym.

HOSTIA, Host, in *Antiquity*, a victim offered in ſacrifice to a deity.

The word is formed from *hoſtis, enemy*; it being the cuſtom to offer up a ſacrifice before they joined battle, to render the gods propitious; or, after the battle was over, to give them thanks Some chooſe to derive the word from *hoſtis*, q. d. *ferio*, *I ſtrike*. Iſidore on this word remarks, that the name hoſtia was given to thoſe ſacrifices which they offered before they marched to attack an enemy; *Antequam*, ſays he, *ad. hoſtem pergerent*, in contradiſtinction from *victims*, which were properly thoſe offered after the victory. Ovid ſeems to diſtinguiſh otherwiſe, when he ſays,

> "Victima quæ cecidit dextra victrice, vocatur;
> Hoſtibus a domitis hoſtia nomen habet."

As if the hoſtia might be ſlain by any prieſt, but the victim only by the hands of the victor. Fronton makes another diſtinction: according to him, *victima* was a grand oblation, and hoſtia a ſmaller and leſs conſiderable one.

HOSTILINA, in *Mythology*, a goddeſs adored among the Romans, and invoked particularly for the fertility of the earth.

HOSTILITY, the action of an enemy. During a truce, all hoſtilities are to ceaſe on both ſides: ſuch a city ſtands neuter, and commits no hoſtilities on either ſide.

The word is Latin, *hoſtilitas*, formed of the primitive *hoſtis*, which ſignifies *enemy*, and which anciently ſignified ſtranger, *hoſpes*.

HOSTILLERS, in our *Old Writers*, is uſed for innkeepers; and in ſome old books the word *hoſters* is taken in the ſame ſenſe. 3 Ed. III. cap. 2.

The word is French, *hoſteliers*, of the ſame import.

HOSTIS, in *Antiquity*. See Bishop.

HOSTOMITZ, in *Geography*, a town of Bohemia, in the circle of Beraun; ſix miles S.E. of Beraun. N. lat. 49° 51′. E. long. 14° 11′.

HOSTORP, a town of Sweden, in the province of Skone; 10 miles N.W. of Lund.

HOT-Bath. See Bath and Thermæ.

HOT-Bed, in *Gardening*, a name given to a ſort of bed conſtructed for the purpoſe of producing artificial heat, and the raiſing of different ſorts of culinary and other vegetables and plants.

In this view theſe beds are moſtly formed either of horſe-dung or tanner's-bark, being raiſed two, three, or four feet high, and covered with garden-frames and glaſſes, &c. And in ſome caſes the dung and bark are mixed or blended together.

It is chiefly by the aid of theſe beds alſo that various tender plants, flowers, and fruits, are raiſed in perfection, which, without ſuch artificial heat, could not poſſibly be produced or continued in this climate. By this means, likewiſe, vaſt numbers of ſeeds, which would otherwiſe remain years in the earth, and ſome never grow at all, are made to generate, form plants, continue their growth, and produce their flowers and fruits as in their native ſoils. And the cuttings and ſlips of many ſorts of trees and ſhrubs, which would otherwiſe remain inactive and periſh, are alſo made ſoon to emit root-fibres and ſhoots, and become plants in due time.

By this means, too, many valuable eſculent plants, that ſucceed in the full ground at one time of the year or other, are brought to perfection much ſooner than they could otherwiſe be obtained, as the cucumber, aſparagus, peas, beans, kidney-beans, radiſhes, carrots, ſtrawberries, and various ſallad herbs, and other plants, which grow in the open ground of the garden departments.

And annual flowering plants, as well as thoſe of the herbaceous and ſhrubby kinds, are alſo brought to more early perfection and flowering by them. They are therefore of great uſe in the practice of gardening, in numerous caſes of forcing early productions.

Making Dung Hot-beds.—The proper ſituations for making theſe ſorts of beds in are the forcing-ground, or other ſheltered, warm, ſunny expoſures, either in or contiguous to the garden ground.

The hot-beds are ſometimes made entirely on level ground, and ſometimes in a trench or oblong cavity formed in the ground, the width and length of the intended bed, and from twelve inches to a foot and a half deep or more; but for early work in the winter or ſpring ſeaſons, they ſhould be moſtly above ground, upon the level or rather elevated ſurface, that the bottom of the bed may ſtand dry, and not be liable to be chilled by wet, as, when made in this way in thoſe ſeaſons when the heat declines, both ſides of the bed may be lined with hot dung quite to the bottom, ſo as the whole may have an equal benefit of the lining to revive its declining heat, which is eſſentially neceſſary during winter and ſpring, until the middle or latter end of May. But when hot-beds are made in trenches at an early ſeaſon, where linings muſt be added to ſupport a conſtant regular heat, all that part of the beds within the ground is deprived of the advantage of them. Theſe beds are ſometimes alſo incloſed by brick maſonry, which is ſurrounded by hot dung on the outſide. This is M'Phail's mode of early forcing.

With reſpect to the forms and dimenſions of dung hot-beds, they ſhould generally be thoſe of long ſquares, ranging nearly eaſt and weſt, to any length that may be convenient; about four feet and a half in breadth, if to be covered with common garden-frames; and three and a half or four feet if for hand-glaſſes; raiſing them, if in winter, or early in ſpring, three or four feet or more in height, allowing for ſettling; as they will ſettle half a foot or more in the courſe of a week or two after making them.

The more early beds ſhould be ſubſtantial, otherwiſe they will not ſupport a durable uniform temperature of heat for continuing the plants in a regular free growth; which, by the aid of linings, muſt be effected till the arrival of warm weather. Thoſe made in winter ſhould be three feet and a half in height at leaſt, when firſt made; or if four, ſo much the better; in March a yard in height, in April the ſame, or two feet and a half; and in May two feet or a little more, as without due ſubſtance they never anſwer well.

Theſe beds may be made for a one-light, a two-light, or even a three-light frame; and for two, three, or more, three-light frames in a range, according to circumſtances and the nature of the forcing to be done.

Manner of Forming the Beds.—After properly marking them out, ſome of the longeſt or moſt ſtrawy dung ſhould be ſhaken along the bottom, to begin the bed with; then the long and ſhort together as it comes to hand, ſhaking it evenly in every part, raiſing the ſides perfectly upright, ſtraight, and firm as poſſible; forming the corners alſo full and very firm, keeping the middle well filled with the beſt dung; and, as the work advances, beating each layer of dung evenly and firmly down with the dung-fork; or, when it is very long, looſe, ſtrawy dung, treading it in to ſettle every part equally; proceeding in this manner till the bed is arrived to its deſigned height, raiſing that part intended for frames two or three inches higher in the back or north ſide than in front, to give the greater ſlope to the glaſſes to the ſun, finiſhing the top even in every part; and when the bed is thus raiſed, trimming up all the ſhort dung remaining at laſt round the bed, laying it on the top ridgeways along the middle, which may either then, or rather, if a ſtrong bed, in a few days afterwards, when the bed has ſettled a little, be levelled, to make good all inequalities, and ſmooth the ſurface. After this ſet the frames, &c. on, and earth the bed as directed below. See FRAME and HAND *Glaſſes*.

The hot-bed being thus formed, when of conſiderable ſubſtance, it may be adviſable to defer the framing and earthing it finally for ſeveral days, or even a week or more according to the ſtrength of the bed, until it is a little ſettled, and the firſt violent heat has ſubſided; as the heat will be very ſtrong, and frequently of a burning nature, for the firſt week or two after it is made. It may, however, often be proper to ſet the frames and glaſſes on, to defend the beds from exceſſive rains or ſnow, as well as to draw up the heat ſooner, to form the bed to a proper temperature for the reception of the mould, and ſeeds or plants. The upper ends of the lights ſhould be raiſed a hand's breadth high, or be ſhoved ſo much down in dry weather, that the great ſteam ariſing from the bed may paſs freely off; as in ſtrong hot-beds neither the earth, ſeed, nor plants, ſhould be put in till the fierce heat and violent ſteam have a little abated. Hot-beds of ſlender ſubſtance may, however, be framed, earthed, &c. as ſoon as made, as no great danger is to be apprehended from burning, and more particularly thoſe for ſmall frames, hand-glaſſes, &c.

Where, in this mode of forcing, there is an extenſive range of ſubſtantial hot-beds, the placing of the frames on them before they are fixed for good, is often inconvenient; in which caſe it is proper to have mats, or dry long litter ready to cover the tops in caſe of exceſſive rains or ſnow, which might chill and retard the beds greatly from becoming of a due temperature for the reception of the earth, &c. and ſometimes occaſion them to become of a burning deſcription, when they otherwiſe would be of only a regular heat and temperature for the purpoſes for which they are deſigned.

But in hot-beds deſigned for ſtrength and duration, it will, as ſoon as they are made, be proper to provide ſome ſharp pointed ſticks, two feet long, to thruſt down into the middle of the beds in different parts, that by pulling them out daily, and feeling their lower parts, a judgment may be formed of the working and temperature of the beds, and when in a proper ſtate for the reception of the mould and plants.

Where the hot-bed is therefore of good ſubſtance, and for the large frames, it is proper to let it remain ſome days to ſettle, before it is framed for good, becauſe, notwithſtanding all the care in making, it will often ſettle unequally; and it ſhould be levelled before it is earthed; in from about three to five, ſix, or eight days, according to the nature of the dung, or ſubſtance of the bed, it will have ſo far ſettled as to diſcover the inequalities, if any; when, if the frames and glaſſes were placed thereon, for the purpoſes above-mentioned, when the whole has ſettled, all the inequalities ſhould be made even, by levelling the top, making the ſurface firm, and ſmoothing it off neatly with the back of the ſpade. Then the frame and glaſſes ſhould be put on for good, opening the lights a little at top to give vent to the ſteam and rank heat.

Mode of Earthing the Beds.—As ſtrong ſubſtantial dung hot-beds, after being covered with the frames, &c. ſometimes heat violently the firſt week or fortnight; when the earth is put in during the fierce heat, by confining that and ſteam ſtill more cloſely it is in danger of being burnt, and alſo of deſtroying the ſeed and roots of the plants, if any were ſown or planted. When the earth is thus burnt by the heat of the dung, no ſeeds or plants can vegetate or thrive in it; it muſt therefore be taken out and replaced by freſh compoſt. Hot-beds of ſuch conſiderable ſubſtance ſhould of courſe be examined previouſly to moulding them, to aſcertain the ſtate of heat daily, by the ſticks, and thruſting the hand into the dung. And when it is found of a due temperature, the mould ſhould be put on. This is ſometimes ſhewn to be the caſe by the appearance of a ſort of muſhroom ſpawn upon the more ſuperficial parts.

But in ſlender hot-beds, as their heat is never ſo violent or durable, they may either be earthed as ſoon as made, or in two, three, or four days afterwards, as may be judged proper. In all caſes care ſhould, however, be taken that the beds do not loſe any time for them to waſte their heat ineffectually, without being earthed and properly prepared for the reception of the plants.

And for all ſorts of hot-beds, the earth or mould ſhould be rich, light, and of a dry quality, particularly for early work in winter and ſpring, and tender plants, ſuch as cucumbers, melons, tender annuals, &c. as very moiſt earth rots ſuch plants while young, binds too cloſely, and by its compactneſs confines the heat and ſteam, ſo as often to burn at bottom, and ſcorch the roots of the plants. Some light mould ſhould therefore always be in readineſs in ſome airy ſhed, for two or three weeks before it is wanted for this uſe. See COMPOST.

In regard to the depth of earth or mould which is neceſſary to be applied over hot-beds, it muſt be different according to the purpoſes for which they are deſigned, as for ſowing ſeed on, or the reception of plants, and the nature of the plants, or chiefly for plunging pots in. In general, however, from about five or ſix, to ten or twelve inches, is the common depth. For ſowing ſeeds to raiſe plants for tranſplantation, the depth of mould ſhould be about ſix inches; and where they are to remain to acquire their full growth, not leſs than from ſix or eight to ten or twelve inches in depth. If for the immediate reception of plants to remain, or for ſtriking cuttings of any ſort in, &c. from ſix to eight, ten, or more inches of mould will be neceſſary, regulating the whole in ſome proportion to the nature or growth of the plants, and the ſubſtance of the beds. Thus, cucumbers and melons, which are not only extenſive growers, but produce large fruit that requires much nouriſhment, need a greater depth of mould than ſmall ſallad-herbs, &c. which only ſtand in need of a ſlight covering.

In the buſineſs of earthing the beds, every part of the dung within the frame ſhould be carefully covered over, eſpecially after the plants are come up, or any planted in them, that no ſteam may riſe immediately from the dung upon them, and thereby prove injurious or deſtructive to them.

With regard to the ſowing or planting ſeeds or plants in hot-beds of ſtrong ſubſtance, under frames, care ſhould conſtantly be taken not to do it till the danger of burning is over, unleſs performed in pots, that may be removed up as occaſion requires; and at any rate, it is always better to wait a day or two, than to endanger the plants; time ſhould not, however, be loſt when the bed is ready, as it is neceſſary always to have a lively heat at firſt, to promote a quick germination in the ſeeds, or to ſtrike and ſet the plants forward, ſo as to aſſume a free growth at firſt when they appear at the ſurface of the beds.

And in the management of hot-beds after being ſown or planted, it muſt often be different, according as the different plants may require. In general, however, after the ſeeds or plants have been put in, the glaſſes are to be conſtantly continued on until the middle of ſummer, when the weather is become ſettled and warm, particularly for all the tender kinds of plants; freſh air being admitted daily, at all opportunities, in mild weather, by raiſing the upper ends of the lights; or, if hand-glaſſes, by propping up one ſide, from about half an inch to two or three inches high, according to the heat and ſteam in the bed, and temperature of the outward air, ſhutting all cloſe in due time towards evening, and keeping them cloſe every night during the cold weather, covering the glaſſes every night with mats until June, eſpecially for the more tender ſort of plants, flowers, &c.

As ſoon as the heat of the beds naturally declines or becomes of a weakly temperature, it muſt be renewed by adding freſh hot dung around the ſides, which is called *lining* the bed, and is particularly neceſſary for all dung hot-beds, made any time in winter or ſpring, as already noticed. See Linings.

And ſometimes a repetition of new linings is required three or four times, eſpecially for thoſe made in winter, to continue them in an uniform heat; theſe linings ſhould be made of the hotteſt dung, and be applied quite from the bottom to the top of the bed, and about fifteen or eighteen inches wide at bottom, drawing them into about a foot wide at top, raiſing them four or five inches up the frame to allow for ſettling, but not more; for the tops of the linings, when ſettled, ſhould be but very little above the bottom of the frame, leſt their heat burn the earth adjoining to the frame within; and to prevent ſteam from riſing too copiouſly from the linings, a ſtratum of earth ſhould be laid on the top two inches thick, continuing it cloſe up to the bottom of the frame, that no ſteam may riſe that way; for the rank ſteam immediately from dung, without firſt paſſing through a body of earth, is deſtructive to moſt plants. As the linings ſettle down lower than the tops of the bed, more freſh dung ſhould be added, in order to preſerve them of a proper height.

Forming Bark Hot-beds.—Theſe are ſuch hot-beds as are formed of bark or tan, after having been uſed in tan-vats or pits, and which produces a regular, moderate, and ſteady durable heat. See Bark and Hot-*houſe*.

But hot-beds of this kind always require to be made in proper bark-pits formed for the purpoſe of brick-work, or poſt and planking, to confine the tan in its proper ſituation and direction. See Bark-*pit*.

In caſes where there are proper conveniences of pits, in which to make the hot-beds furniſhed with frames and glaſſes ſuitable, they are ſuperior in many caſes to dung hot-beds, both in raiſing many early eſculent productions, and various curious flowers to early bloom, as well as in the propagation and raiſing many ſorts of tender exotics, from ſeeds, layers, cuttings, &c. In bark hot-beds early ſtrawberries and melons may be raiſed, which, by the regular, moderate, and durable heat which they produce, are generally in great perfection at an early ſeaſon; likewiſe, ſmall early crops of dwarf-peas and kidney-beans, &c. and of flowering plants, many ſorts may be forced in great perfection of early bloom, both of the bulbous, tuberous, and fibrous-rooted kinds, ſuch as hyacinths, dwarf-tulips, jonquils, narciſſuſes, anemones, ranunculuſes, pinks, and many other moderate growing kinds; alſo roſes, and ſome other ſmall ornamental flowering ſhrubs of different deſcriptions.

And bark hot-beds are alſo of great utility in hot-houſes, ſtoves, and forcing houſes, as the principal and moſt proper, and effectual kind of beds for theſe different departments of the garden. See Bark-*beds*, and Hot-*houſe*.

Kinds of forced Crops.—The particular ſorts of crops uſually raiſed in theſe hot-beds are thoſe of cucumbers, melons, aſparagus, ſtrawberries, kidney-beans, peas, dwarf-beans, radiſhes, ſmall ſallad-herbs, and lettuces. But various ſorts of ſeed plants are raiſed and preſerved in this way, ſuch as cauliflowers, early cabbages, red cabbages, early celery plants for pricking out, carrots, ſmall white turnip-radiſhes, Dutch turnips, mint, tarragon, tanſey, baſil, capſicums, love-apples, coriander, purſlane, early dwarf potatoes, and muſhrooms in beds of peculiar ſorts. But thoſe for which theſe beds are more abſolutely neceſſary, are all the firſt ſort, and baſil, capſicum, love-apple, and muſhrooms amongſt thoſe of the ſecond deſcription. See Mushroom-*houſe*.

Hot-*bed*, in *Agriculture*, a ſort of earthy layer or ſtratum, under which horſe and ſome other kinds of manure have been depoſited in their more raw and imperfectly reduced conditions; by means of which a degree of heat is kept up for ſome length of time, and thereby vegetation brought forward, where the ſeaſon or climate is not warm enough for effecting the purpoſe in a proper manner. This is a method of huſbandry that can only be had recourſe to in particular ſorts of crops, ſuch as thoſe of potatoes and a few others, in which the ſets or other ſeeds are capable of being put in upon littery or other hot dung in the drills or rows, by means of which a kind of hot-bed is prepared for the promotion of their growth, and the extenſion of their knobby, tuberous, or other roots.

Hot-*bed Culture*, a term applied to that kind of cultivation which in ſome meaſure approaches to that which takes place on hot beds. See Hot-*bed*.

Hot-*houſe*, in *Gardening*, a ſort of garden erection, moſtly formed of glaſs-work, in which a conſtant regular degree of artificial heat by fire and bark hot-beds is kept up and preſerved.

The principal powers which aſſiſt in promoting the growth of vegetables, and which of courſe ſhould be regarded in buildings of this nature, are thoſe of heat, light, air, earth or ſoil, and water. The firſt of theſe is commonly afforded by the conſumption of ſome ſort of material as fuel, in a narrow fire-place or furnace, the heat and ſmoke being conveyed in a winding horizontal flue or pipe, which ſerves as a chimney to the different parts. This has, likewiſe, been occaſionally done by the application of ſteam alone, as well as in combination with fire. This is, however, too expenſive a method to be generally employed. It may be afforded alſo by different materials in the ſtate of fermentation, ſuch as dung, litter, leaves, and various other vegetable products of little value but for manure. And in particular ſituations it may be effected by the ſun, being preſerved by proper contrivances, as in the patent hot-houſe lately invented by Dr. Anderſon, and deſcribed below. But though all theſe ſchemes may be occaſionally had recourſe to in particular caſes, that by the conſumption of fuel in furnaces and flues is the only practical method that can be generally adopted with benefit. As the principal difficulty in this buſineſs is the regulation and retention of the temperature, ſo as to ſuit the different habits and degrees of heat that are requiſite for the growth of the different plants; various plans have been had recourſe to in theſe intentions; in the latter partly by having the houſes made in a great meaſure air-tight, and partly by the contrivance of an inner curtain, ſo as to be let down cloſe under the glaſs during the night-time, and thereby prevent the heated air of the houſe from being brought in contact with it, and from eſcaping in any great proportion in that way. This curtain has been lately contrived by Mr. Loudon. In the former, the heat is alſo chiefly regulated and kept at the proper height by means of this curtain, which, as it keeps up the due temperature, does not render it neceſſary to have the heat raiſed ſo much in the early part of the night, in order to avoid its getting too low towards the morning. For though the houſe be quite air-tight, as glaſs from its porous nature is readily permeable by heat or cold, it muſt of neceſſity, in conſequence of the aſcenſion of the heated air to the top of the houſe, be continually given out to the ſurrounding atmoſphere by the roof and ſides of all glazed houſes of this deſcription. It is indeed principally on this account that ſuch houſes as have their ſides of glaſs, are, without this ſort of curtain, conducted with ſuch trouble and difficulty.

Light is neceſſarily admitted by having the whole or a portion only of the roof of ſuch houſes; or all the roof and ſides too, conſtructed with glaſs, in frames that have the convenience of ſliding at pleaſure. It is of very great importance in theſe buildings alſo, that the light ſhould fall upon the plants, at but a ſmall diſtance from the glaſs of their roofs, as by ſuch means the plants are found to ſucceed in the moſt perfect manner.

Air is obviouſly incloſed within ſuch houſes, but is capable of being excluded, and that which is freſh admitted either in the whole or only in part, ſo as to be intermixed with it, by means of proper openings or apertures formed in different parts, ſo as to be opened or cloſed as there may be occaſion for the due growth of the plants.

Earthy matter or ſoil proper for this purpoſe may be provided by means of incloſing a part of the ſurface of the ground within ſuch houſes, and putting it under a ſuitable ſtate of preparation, as well as by depoſiting it after being properly prepared in pots or boxes made for the purpoſe, and which are capable of being put in any way that may be found beneficial for the plants or other things they may contain.

Water can readily be given in its ſtate of fluidity to the plants or other crops ſimply by pouring it over the ſurface of the earth, or by the garden ſyringe, engine, and watering-pot, as rain; and by pouring it upon the heated flues or other parts of the houſe by which it is converted into vapour, it is applied as dew, in conſequence of its being depoſited in fine particles as it loſes its heat.

Beſides theſe, the removal of ſtagnant air in theſe ſorts of houſes is of much conſequence, which may in ſome meaſure be effected by affording motion to the plants by the admiſſion of the external air in gentle currents. But as this can only be properly attempted when the air from without is nearly of the ſame temperature as that of the hot-houſe, it is plain that plants grown in ſuch places can only have ſuch admiſſions for a very ſmall part of the year. This has led to different contrivances in order to remedy the defect, but theſe have hitherto been attended with but little ſucceſs.

General Conſtruction and Uſe.—The hot-houſe is uſed for procuring ſome ſorts of fine fruits, ſuch as the peach, the nectarine, the cherry, the fig, &c. alſo for the vine, the pine-apple, and for raiſing and preſerving various other ſorts of tender exotics from the hot parts of the world. Each of theſe ſorts of fine fruits requires ſomething particular in the conſtruction of the hot-houſe.

Thoſe which are intended for the peach, nectarine, cherry, and fig, &c. are in general with great propriety in cold ſituations conſtructed againſt walls, being made with glaſs on one ſide. But in climates that are leſs ſevere, ſuch houſes as are formed of glaſs on all the ſides, having the trees ſo planted as to grow irregularly in the ſtandard method, may be more beneficial as well as more ornamental.

For the forcing of vines, they may be of any kind of form as well as ſmall or large, according to the ſeaſon at which the trees are to be brought into fruit. But a double-roofed houſe, with an inner roofing, is adviſed by ſome as the moſt proper for general crops, as well as the moſt cheap in its nature.

It is uſual for pines to be raiſed at very great expence, in conſequence of the quantities of tan, leaves, and other ſimilar ſubſtances that are neceſſary, and which ſtand in need of ſuch frequent renewal, and cauſe ſo much labour and trouble in removing and replacing the plants, &c. in their ſituations. Theſe, with the uncertainty that is naturally attendant on forcing with materials under the ſtate of fermentation, have deterred many from attempting this ſort of culture. Lately, however, plans have been ſuggeſted and put in practice, which in a great meaſure obviate theſe inconveniences, as may be ſeen in the ſection of a pinery given in the plate for this purpoſe.

But in the general conſtruction of theſe houſes, a wall of eight or ten feet in height or more, is raiſed behind, with a low wall in front and both ends, on which is placed upright glaſs-work, four, five, or ſix feet, and a ſloping glaſs roof, extending from the top of the front to the back wall. Internal flues for fire-heat, in winter, are alſo contrived, and a capacious oblong or ſquare pit in the bottom ſpace, in which to have a conſtant bark-bed to furniſh a continual regular heat at all ſeaſons; ſo as in the whole to warm the incloſed internal air always to a certain proper high degree. Houſes thus formed are moſtly uſed in raiſing pines.

But beſides the above, theſe houſes are of great utility in forwarding many ſorts of choice or deſirable hardy plants, flowers, and fruits to early perfection, which being ſown or planted in pots, and placed in them in winter, or early in ſpring, the conſtant heat thus produced forwards them to maturity two or three months or more before their natural ſeaſon in the full ground, ſuch as kidney-beans, ſtrawberries, &c.; alſo, many ſorts of flowering plants, both annuals and perennials, of moderate growth, are forwarded to early bloom; and vines planted in the outſide cloſe to the front, the ſtem of each introduced through a ſmall hole above, and the internal branches trained up under the glaſſes, produce grapes at an early period, as in May. In hot-houſes, likewiſe, early cucumbers may be raiſed in good perfection; and the ſeeds, cuttings, ſlips, &c. of many curious tender plants forwarded exceedingly in their growth by plunging the pots containing them in the bark-beds of ſuch houſes.

Situation and Form.—Theſe houſes are moſtly ranged lengthways, nearly eaſt and weſt, that the glaſſes of the front and roof may have the full influence of the ſun. This is the moſt convenient ſituation for common houſes, either for pines or exotic plants.

But ſome houſes of this ſort, inſtead of being placed in this direction, have lately been ranged directly ſouth and north, having a ſloped roof to each ſide like the roof of a houſe; alſo to the front or ſouth end; both ſides and the ſouth end front being of glaſs. Theſe houſes are made from ten or twelve to fifteen or twenty feet wide, the length at pleaſure; and from ten to twelve feet high in the middle, both ſides fully head height; being formed by a brick wall all round, raiſed only two or three feet on both ſides, and ſouth end; but at the north end like the gable of a houſe. Upon the top of the ſide and ſouth end walling is erected the framing for the glaſs-work, which is ſometimes formed two or three feet upright, immediately on the top of the wall, having the ſloped glaſs-work above; and ſometimes wholly of a continued ſlope on both ſides, immediately from the top of the ſide walls to that of the middle ridge. They are furniſhed either with one or two bark-pits; but if of any conſiderable width, generally with two ranging parallel, one under each ſlope of the top glaſs, ſeparated by a two-foot path running along the middle of the houſe, and ſometimes continued all round each pit, with flues ranged along againſt the inſide walls; the whole terminating in an upright funnel or chimney at the north end of the building.

There are other hot-houſes which are formed entirely on the ſquare, having a ten or twelve-feet brick wall behind; that of the front, and both ſides, only two or three feet high for the ſupport of the glaſs-work, placed nearly upright almoſt the ſame height, and ſloped above on both ſides and front, which are wholly of glaſs. Theſe are furniſhed within with bark-pits and flues, as in the other ſorts.

In particular caſes they are likewiſe made ſemicircular, or entirely circular, being formed with a two or three-feet brick wall ſupporting the glaſs framing, which is continued quite round; having the bark-pit alſo circular, and flues carried all round the inſide of the walling, terminating in a chimney on the northern ſide of the houſe. However, the firſt forms are probably the beſt for general purpoſes.

Dimenſions.—Hot-houſes on theſe plans are made of different dimenſions, according to the ſize of the plants they are deſigned to contain; but for common purpoſes they ſhould be only of a moderate height, not exceeding ten or twelve to fourteen feet behind, and five or ſix in front: ſome are, however, built much more lofty behind, to admit of the taller growing exotics placed toward the back part, to grow up accordingly in a lofty ſtature; but the above are beſt adapted to the culture of pines, and other moderate growing plants, as well as for forcing in; as very lofty houſes require a greater force of heat, and by the glaſſes being ſo high, the plants receive leſs benefit from the ſun, and are apt to draw up too faſt into long ſlender leaves and ſtems, as they naturally tend towards the glaſſes. Where the top glaſſes are at a moderate diſtance from the plants, they receive the benefit of the ſun's heat more fully, which is eſſential in winter, and become more ſtalky at bottom, and aſſume a more robuſt and firm growth, particularly the pine-apple, and are thereby more capable of producing large fruit in the ſeaſon.

Conſtructing the Flues.—After having determined on the dimenſions as to length and width, the foundations of the houſe ſhould be ſet out accordingly of brick work, allowing due width at bottom to ſupport the flues a foot wide, wholly on the brick baſis; detached an inch or two from the main walls; then ſetting off the back or north wall a brick and a half or two bricks thick, and the front and end walls nine inches, carrying up the back wall from ten to fourteen feet high; but thoſe of the front and ends only from about two feet to a yard; taking care in carrying up the walls to allot a proper ſpace for a door-way, at one or both ends, towards the back part; ſetting out alſo the furnace or fire-place of the flues in the bottom foundation, towards one end of the back wall behind, formed alſo of brick work, made to communicate with the lowermoſt flue within. But when of great length, as forty feet or more, a fire-place at each end may be neceſſary; or, if more convenient, may have them in the back part of the end walls, or both in the middle way of the back wall; each communicating with a ſeparate range of flues; in either caſe, forming them wholly on the outſide of the walls, about twelve or fourteen inches wide in the clear, but more in lengthways inward; the inner end terminating in a funnel to communicate internally with the flues, fixing an iron-barred grate at bottom to ſupport the fuel; calculated for coal, wood, peat, turf, &c. An aſh-hole ſhould be made underneath. The mouth or fuel-door ſhould be about ten or twelve inches ſquare, having an iron frame and door fixed to ſhut with an iron latch as cloſe as poſſible. The whole furnace ſhould be raiſed ſixteen or eighteen inches in the clear, finiſhing the top archways. Then continue carrying up the walls of the building regularly, and on the inſide erect the flues cloſe along the walls.

It is ſometimes advantageous to have the flues a little detached from the walls, one, two, or three inches, that, by being thus diſtinct, the heat may ariſe from both ſides, which will be an advantage in more effectually diffuſing the whole heat internally in the houſe; as, when they are attached cloſe to the walls, a very conſiderable portion of the heat is ineffectually loſt in the part of the wall behind. In contriving the flues, they ſhould be continued along the front and both ends, in one range at leaſt, in this order. But it is better if they are raiſed as high as the outward front and end walls, in one or two ranges, one over the other. On the tops of theſe may be placed pots of many ſmall plants, both of the exotic and forcing kinds, with much convenience.

Thus proceed in the conſtruction of the flues, making them generally about a foot wide in the whole, including ſix or eight inches in the clear, formed with a brick work, on edge; the firſt lower flue ſhould communicate with the furnace or fire-place without and be raiſed a little above it, to promote the draught of heat more freely, continuing it along above the internal level of the floor of the back alley or walk of the houſe the above width, and three bricks, on edge, deep, returning it in two or three ranges over one another, next the back wall, and in one or two along the ends, and front wall as the height may admit; each return two bricks, an edge deep, and tiled or bricked over. In the beginning of the firſt bottom flue a ſliding iron regulator may be fixed, to uſe occaſionally, in admitting more or leſs heat, being careful that the brick-work of each flue is cloſely jointed with the beſt ſort of mortar for that purpoſe, and well pointed within, that no ſmoke may break out; having each return cloſely covered with broad ſquare paving tiles on the brick-work; covering the uppermoſt flues alſo with broad, thick, flat tiles the whole width, all very cloſely laid, and joined in mortar. The uppermoſt or laſt range of flues ſhould terminate in an upright vent or chimney at one end of the back wall; and where there are two ſeparate ſets of flues, there ſhould be a chimney at each end. An iron ſlider in the termination of the laſt flue next the chimney may alſo be provided, to confine the heat more or leſs on particular occaſions, as may be found neceſſary.

But ſometimes, in very wide houſes, in erecting the flues, to make all poſſible advantage of the fire-heat, one or more ſpare flues, for occaſional uſe, is continued round the bark-pit, carried up againſt the ſurrounding wall, but detached an inch or two, to form a vacancy for the heat to come up more beneficially, and that, by having vent, it may not dry the tan of the bark-bed too much; and in the beginning a ſliding iron regulator may be fixed, either to admit or exclude the heat, as expedient; ſo that the ſmoke, by running through a larger extent, may expend its heat wholly in the flues before it be diſcharged at the chimney. Great care muſt likewiſe be taken that neither the fire-place nor flues be carried too near any of the wood-work of the buildings.

Bark-pit.—After this work is done proceed to ſet out the cavity for the bark-pit, firſt allowing a ſpace next the flues for an alley or walk, eighteen inches or two feet all round, and then in the middle ſpace form the pit for the bark-bed ſix or ſeven feet wide, the length in proportion to that of the houſe, and a yard or more deep; incloſing it by a ſurrounding wall. It may either be ſunk at bottom a little in the ground, raiſing the reſt above by means of the parapet wall; or if there is danger of wet below, it ſhould be raiſed moſtly above the general ſurface. The ſurrounding wall ſhould be nine inches, but a brick wide wall is often made to do, eſpecially for that part which forms the parapet above ground. It ſhould be coped all round with a timber plate or kirb, framed and mortiſed together, which effectually ſecures the brick-work in its proper ſituation.

The bottom of the pit ſhould be levelled and well rammed, and if paved with any coarſe material, it is an advantage in preſerving the bark. And the path or alley round the pit muſt be neatly paved with brick or ſtone, as may be moſt convenient

Glaſs-work.—The glaſs part for incloſing the whole ſhould conſiſt of a cloſe-continued range of glaſs-ſaſhes all along the front, both ends and roof, quite up to the back wall; each ſaſh being a yard, or three feet ſix inches wide; and for the ſupport of which, framings of timber muſt be erected in the brick-walling, conformable to the width and length of the ſaſhes, the whole being neatly fixed.

And for the reception of the perpendicular glaſſes in the front and ends, a ſubſtantial timber plate muſt be placed along the top of the front and end walls, upon which ſhould be erected uprights, at proper diſtances, framed to a plate or crown-piece above, of ſufficient height to raiſe the whole front head high, both ends correſponding with the front and back; a plate of timber being alſo framed to the back wall above, to receive the ſloping bars from the frame-work in front; proper grooves being formed in the front plates below and above, to receive the ends of the perpendicular ſaſhes, ſliding cloſe againſt the outſide of the uprights all the way along the front, or they may be contrived for only every other ſaſh, to ſlide one on the ſide of the other, but the former is the better method.

And from the top of the upright framing in front ſhould be carried ſubſtantial croſs-bars or bearers, ſloping to the back wall, where they are framed at both ends to the wood-work or plates, at regular diſtances, to receive and ſupport the ſloping glaſs ſaſhes of the roof, when placed cloſe together upon the croſs bars or rafters, and generally ranging in two or more tiers, ſliding one over the other, of ſufficient length together to reach quite from the top of the upright framing in front, to the top of the back wall. The croſs bars ſhould be grooved lengthways above, to carry off wet falling between the frames of the ſloping lights: making the upper end of the tier of glaſſes ſhut cloſe up to the plate in the wall behind, running under a proper coping of wood or lead, fixed along above cloſe to the wall, and lapped down of due width to cover, and ſhoot off the wet ſufficiently from the upper termination of the top ſaſhes. Some wide houſes have, excluſive of the main ſlope ſliding glaſs ſaſhes, a ſhorter upper tier of glaſs fixed; the upper ends being ſecured under a coping as above, and the lower ends lapping over the top ends of the upper ſliding tier, and this over that below in the ſame manner, to ſhoot the wet clear over each upper end or termination; likewiſe along the under outer edge of the top plate, or crown piece in front, may be a ſmall channel to receive the water from the ſloping glaſs ſaſhes, and convey it to one or both ends without running down upon the upright ſaſhes, being careful that the top part behind be well framed and ſecured, water-tight, and the top of the back wall finiſhed a little higher than the glaſſes, with a neat coping the whole length of the building.

And the bars of wood which ſupport the glaſſes ſhould be neatly formed, and made neither very broad nor thick to intercept the rays of the ſun. Thoſe however, at top, ſhould be ſtrong enough to ſupport the glaſſes without bending under them. In wide houſes, uprights are arranged within, at proper diſtances, to ſupport the croſs rafters more perfectly than could otherwiſe be the caſe.

Glazing.—But in reſpect to the glaſs work in the ſloping ſaſhes, the panes of glaſs ſhould be laid in putty, with the ends lapping over each other about half an inch, the vacancies of which are, in ſome, cloſed up at bottom with putty, others leave each lapping of the panes open, in order for the air to enter moderately, and that the rancid vapours ariſing from the fermentation of the bark-bed, &c. within, may thereby be kept in conſtant motion, without condenſing much, and alſo that ſuch as condenſe againſt the glaſſes may diſcharge themſelves at thoſe places without dropping upon the plants. The upright ſaſhes in front may either be glazed as above, or the panes laid in lead work; being very careful to have the glazing well performed, and proof againſt any wet that may happen to beat againſt them. The doors ſhould have the upper parts ſaſhed and glazed to correſpond with the other glaſs-work of the houſe.

Painting.—And on the inſide, the walls ſhould be plaſtered, pargeted, and white-waſhed; and all the wood-work within and without, painted white in oil colour. Some, however, have the back wall painted or coloured rather dark.

Shelves.—Ranges of narrow ſhelves for pots of ſmall plants may be erected where moſt convenient, ſome behind over the flues, a ſingle range near the top glaſſes towards the back part, ſupported either by brackets ſuſpended from the croſs bars above, or by uprights erected on the parapet wall of the bark-pit. A range or two of narrow ones may alſo be placed occaſionally along both ends above the flues where there is a neceſſity for a very great number.

In wide houſes, where the croſs bars or bearers of the ſloping or top glaſs ſaſhes appear to want ſupport, ſome neat uprights, either of wood or iron, may be erected upon the bark-bed walling, at convenient diſtances, and high enough to reach the bearers above. This is a neat mode of affording them ſupport.

And on the outſide, behind, ſhould be erected a cloſe ſhed, the whole length, or at leaſt a ſmall covered ſhed over each fire-place with a door to ſhut, for the convenience of attending the fires; but the former is much the beſt, as it will ſerve to defend the back of the houſe from the outward air, and to ſtow fuel for the general uſe of them, alſo for garden tools, and all garden utenſils when not in uſe, to preſerve them from the weather; as well as to lay portions of earth in occaſionally, to have it dry, for particular purpoſes in winter and early ſpring, as in forcing frames, &c.

Sometimes hot-houſes are furniſhed with top covers, to draw over the glaſs ſaſhes occaſionally, in time of ſevere froſts and ſtorms; and ſometimes by ſlight ſliding ſhutters, fitted to the width of the ſeparate ſaſhes; but theſe are inconvenient, and require conſiderable time and trouble in their application. At other times they are formed of painted canvas, on long poles or rollers, fixed lengthways along the tops of the houſes juſt above the upper ends of the top ſaſhes, which, by means of lines and pullies, are readily let down and rolled up as there may be occaſion.

In the plate of *Hot-houſe*, at *figs.* 1. and 2. are contained the front elevation and ground plan of an improved hot-houſe, which has been found to anſwer well in practice in different inſtances.

At *fig.* 3. is ſhewn the ſection of a hot-houſe for pines, in which the objections ariſing from the expence and riſk attending their culture on the old plan are chiefly obviated. It is the invention of Mr. Loudon. In this, A, A, A, are the ſmoke flues; B, the air flue; C, a large vacuity of heated air; D, the rubble ſtone vacuity; E, the walk in the centre; F, earth in which the plants grow; G, ſteam and air tubes; H, the inner roofing; I, the ſurface of the ground. See Loudon's Treatiſe on Hot-houſes.

A plan for another kind of improved hot-houſe has been ſuggeſted by Dr. James Anderſon, for which he has taken out a patent. It produces its effects chiefly by the heat of the ſun, without the aid of flues, tan-bark, or ſteam. This improvement extends to every ſort of hot-houſe; and the advantages of ſuch hot-houſes are, according to the ſtatement the doctor has given, very conſiderable. They are,

1ſt. That "in every kind of temperature, if the works are to be erected new, from the foundation, few caſes can occur, in which they may not be ſo placed, as that the whole heat required may be obtained without occaſioning the expenditure of one ſhilling for fuel; but in the moſt unfavourable caſes that can occur, the expenditure of fuel will not amount to one-tenth part of what is now univerſally employed for producing ſimilar effects."

2d. That "in a vinery, for example, where the grapes are not meant to be forced farther than to ripen from the middle of June to the end of July, as the ſeaſon may be, no fuel will, in any caſe, be required, the whole effect being produced by the ſun alone."

3d. That "where the grapes are to ripen in April or May, ſome artificial heat will be wanted; but the quantity of fuel, even in this caſe, will be ſo inconſiderable, that in a houſe which produces, on an average of years, under ordinary good management, not leſs than ten thouſand full-ſized bunches of grapes, and fifteen hundred pots of ſtrawberries, or other ſuch plants, the conſumption of fuel will not exceed half a London chaldron of coals, and ſo in proportion for thoſe of a larger extent."

4th. That "in the pinery and ſtove, the expenditure of fuel will be diminiſhed in a proportionate degree; while, at the ſame time, the uſe of bark (or of ſteam, as a ſubſtitute for the heat of tan) will be entirely diſpenſed with; which, in many ſituations, will be the ſaving of much expence."

5th. That "theſe ſavings of expenditure will be effected not only without any detriment to the pines and other plants, but with great advantage to them all; for, in conſequence of theſe improvements, thoſe diſeaſes which ſo much weaken, and often deſtroy the moſt valuable plants, the damp in particular, will be entirely removed, and vermin, in a great meaſure, annihilated; the plants too, in conſequence of the ventilation that may be at all times given them at pleaſure, to any degree that ſhall be thought proper, (without varying the temperature from that degree which may be deemed moſt ſalutary to the plants, at the ſame time that it may be changed, at will, from moiſt to dry, or the reverſe,) may be kept in a ſtate of perpetual health and luxuriance that has been hitherto unknown in theſe repoſitories." And,

6th. That "all theſe effects will be produced by ſuch a ſimple apparatus, and that ſo adapted as to moderate of itſelf extremes of every ſort, that it will become a matter of much leſs nicety and trouble to the gardener than at preſent; as he may ſafely be abſent for a much longer time; and thus the accidents which originate from negligence leſs frequently occur."

It may be noticed that theſe houſes are made almoſt wholly of wood and glaſs. The baſe is a frame of wood, which reſts horizontally upon poſts fixed firm in the ground, to which the frame is ſcrewed by ſtrong iron ſcrews; the whole being ſo conſtructed as to admit of being taken down and removed at pleaſure without violence, merely by undoing the ſcrews. They are capable of being formed of any dimenſions. But a full explanation of their nature, and the principles on which they produce their effects, may be ſeen in the doctor's work on the "Patent Hot-houſe," lately publiſhed. Hot-houſes on this plan are conſtructed by George Byfield, eſq. architect, Craven ſtreet, Strand, London; and Mr. Samuel Butler, Hot-houſe-builder, Little Chelſea, near London.

Making Nurſery and Succeſſion Houſes.—It muſt be obſerved, that in addition to theſe hot-houſes, others of ſmaller dimenſions, for ſtriking and raiſing the young plants in, and as ſucceſſion houſes for receiving them into afterwards, when of a year's growth, to bring them forward to a proper ſize for being uſed as fruiting plants, are neceſſary, eſpecially where the pine-apple is cultivated upon an extenſive ſcale, in order to afford full room in the larger houſes for the fruiting plants to grow properly in.

Theſe houſes may be erected either as appendages to the main houſe, or detached at a little diſtance, as moſt convenient. Where the ſituation admits, it is, however, more convenient and ornamental to join them in a line with the main houſe, one at each end. They are formed nearly on the ſame conſtruction, only ſmaller both in length, width, and height, than the hot-houſe.

Form of Nurſery Houſe.—This is ſometimes formed in the manner of a common detached bark-pit, without any upright glaſſes in front, having a wall all round, five or ſix feet behind, gradually ſloping at each end, to about four feet in front, and with only ſliding glaſſes at top. Its dimenſions muſt vary according to the extent of plants. It is often termed ſimply the pit, as the whole internal ſpace in length and width is allotted entirely as a pit for a bark-bed, without any walk within, or door for entrance, the neceſſary culture being performed by ſliding up the glaſſes at top, the flues for the fires being formed in the upper part of the back wall, above the ſurface height of the bark-bed. They may, however, be formed in the manner of the hot houſe, with doors, &c. which is perhaps the beſt method. One on this principle, for general purpoſes, has lately been conſtructed on a ſmall ſcale, by Mr. Loudon, which, merely by one fire, is capable of affording four different temperatures at the ſame time, and of courſe, of forcing moſt ſorts of common vegetables, as well as growing vines, pines, and melons, each in their ſuitable climates, at little trouble or expence. A ſurface plan of it is given in the annexed plate, in which A ſhews the cover of the excavation, compriſing the furnace; B, the air regiſters, which ſerve to form the different temperatures; C, the air and ſteam tubes, by which the heated air is admitted from the vacuity formed by the rubble ſtone, as well as by the ſteam afforded by pouring in water, &c. In the ſection of this pit in the ſame plate, A repreſents the ſmoke flue; B, the air flue; C, the chimney; D, the ſupports of the rubble vacuity; E, the rubble cavity; F, the earth and the plants; G, the inner roofing rolled up; H, the damper; I, the furnace hole; K, the cover of the ſame; L, the ſurface of the ground, &c. There are many advantages derived from this mode of conſtruction, as thoſe of ſaving labour, expence, and littering the garden ground; and by ſlight alterations it will be found to anſwer cheaply for the buſineſs of forcing vines. See Loudon on Hot-houſes.

Form of Succeſſion Houſe.—This ſort of houſe ſhould be conſtructed with erect glaſſes in front, and ſloping ſaſhes at top, with a door for entrance, and an alley or walk next the back wall; or, what is better, continued round the bark-pit. And where joined to the end of the hot-houſe, it may be divided from it by a ſliding glaſs partition, having a ſeparate furnace and flues, as the young pine plants do not at all times require the ſame degree of fire-heat as the older pines. The dimenſions muſt vary according to circumſtances, and the number of plants. See Stove and Green-*houſe.*

Hot-*houſe Plants*, are all ſuch of the tender, exotic, or other kinds, as require this ſort of houſe for their growth, protection, and preſervation, in this climate. This deſcription of plants is very extenſive, and of many different kinds. See Stove *Plants.*

Hot-*houſe*, in the *Salt Works*, the place where they dry the ſalt after it is taken out of the boiling pan. In the Cheſhire ſalt-works, this is ſituated between the furnace and the funnels of the chimney which convey up the ſmoke. Along the floor of this room there run two funnels, nearly in a horizontal direction. From the furnace, after this courſe along the floor, they riſe perpendicularly. In theſe the flame and ſmoke running along, heat the room by the way.

Hot-*ſhoots*, or *Hovilſes*, a ſort of factitious, or compound fire, made of a third part of any coal, pit, ſea, or charcoal, mixed with two-thirds of loam.

Theſe ingredients are to be made up into balls, moiſtened with a little urine, round, or in any other form, at pleaſure, and expoſed to the air till thoroughly dry; then may they be burnt in the moſt orderly fire imaginable, affording a glowing, regular, and conſtant heat, for ſeven or eight hours, without ſtirring. This mixture is alſo uſed in ſome parts to ſlacken the impetuous devouring of the fire, and keep coals from conſuming too faſt.

Hot *Springs*, in *Geology*. A great part of the writers on thermal waters have aſcribed their heat to ſubterranean fires, ſeated deep in the earth, and have ſuppoſed that the waters of hot and warm ſprings were all alike boiling hot, until by their paſſage through different maſſes of cool ſtrata, they were reduced to the temperature at which they iſſue. Mr. Farey's recent examination and report on Derbyſhire, vol. i. ſhews, that the hot or warm ſprings at Buxton, Matlock Bath, Stoney-Middleton, &c. are ſituated on or near the principal faults or vertical derangements of ſtrata in theſe diſtricts, and the probability that ſhale, brought in contact with toadſtone, in the faces of theſe faults, excites the fermentation, or decompoſition, which developes the conſtant heat of theſe curious ſprings. See Mineral *Waters.*

Hot *Wall*, in *Gardening*, a term applied to a range or extent of brick or ſtone walling, fronted with glaſs-work, ſo as to incloſe a ſpace of ſeveral feet in width, conſtructed with internal fire-flues, &c. deſigned for forcing fruit-trees to early production. It conſiſts of two parts, the flues and furnace in the wall; and the contrivance of a covering of canvas or netting to protect the trees.

Situations of this nature are moſtly ranged lengthways, eaſt and weſt, to front the full ſun; having the ſouth ſide, or that expoſed to the ſun, covered by a frame-work of glaſs, the whole length and height, including a ſpace of but moderate width, as four, five, ſix, or eight feet for one row of trees behind, trained in the wall-tree order, and extended from twenty or thirty, to forty, fifty, or a hundred feet in length; or of greater width, as ten, twelve, or fifteen feet, in the forcing-houſe manner, to admit of a range of trained trees behind, and others of lower growth forward; and, in either having internal flues for fire-heat in the main-wall, and continued round along towards the front glaſs, or ſometimes ranged longitudinally along the middle ſpace. Some hot-walls have likewiſe the front incloſure of glaſs-work, of ſufficient width to admit of forming an internal pit, from four to five or ſix feet in width, the length of the erection; in which to make a bark-bed, or ſometimes a dung hot-bed, or occaſionally dung below and bark above, to aſſiſt, in conjunction with the fire-heat of the flues, in warming the internal air of them.

And in either method, a border of good mellow, loamy, or other fertile earth of proper width, is formed againſt the main-wall, in which to plant the trees. Where there is no bark-bed, the whole bottom ſpace is formed with good earth, having a narrow incloſure of glaſs, four, five, or ſix feet, to have only a range of trees next the wall, trained as wall-trees, or eſpaliers; or ſometimes made wider, to have wall-trees behind trained to the height of the wall, and others trained, in lower growth, in the internal ſpace forward, either in the eſpalier manner, or as ſmall dwarf-ſtandards, or ſometimes as horizontal dwarfs. See Dwarf *Trees.*

When theſe are made of wide dimenſions, either to admit of a bark-pit, or to have the whole bottom ſpace of earth ſet with trees againſt the wall, and others planted forward between theſe and the glaſſes, they may properly be conſidered as forcing-houſes.

But in proper hot-walls, as ſuch as have narrow incloſures of glaſs from four to five or ſix feet in width, containing only one range of trees, they may be trained towards the wall upon a trellis-work, where there is a range of flues immediately next the wall; but where all the flues are ranged forward, the trees may be trained cloſe to the wall. See Forcing-*frame.*

The flues in theſe walls ſhould be formed in ſuch a way as to diſtribute the heat equally over the wall, which is eaſily effected. The fronts of them ſhould be made at leaſt a brick in thickneſs, to preſerve the heat more effectually. The moſt proper furnace for this uſe is that ſold by Mr. Cook in London, and connected with a damper, which is very uſeful. The covering of canvas, gauze, or netting of the ſmall kind, ſhould be fixed to the wall top, by means of ſmall rafters, and to the border, about three feet from the roots of the trees; the roller for containing this covering being faſtened to the bottom parts of theſe rafters. By this means, and the uſe of cords and pullies, ſuch coverings can eaſily be drawn up to the top of the wall, or be rolled down, as there may be occaſion. This covering ſhould never be neglected in ſuch walls, as it is of vaſt utility in preſerving the heat, as well as in preventing the effects of deſtructive froſts and chilly dews at particular ſeaſons. See Bark-*pit*, and Pit.

HOTAMBÆIA, in *Zoology*, the name of a ſpecies of ſerpent found in the Eaſt Indies, of a greyiſh-yellow colour, and very rank ſmell.

HOTCH, in *Agriculture*, a term provincially applied to a bad job of any ſort of work, or to ſuch bargains as do not turn out well.

HOTCH-POT, in *Law*, ſignifies a mixture or blending of lands, given in marriage, with other lands in fee accruing by deſcent. Thus, a man ſeized of thirty acres of land in fee, hath two daughters, and gives with one of them ten acres in frank-marriage, and dies ſeized of the other twenty. If now, ſhe that is thus married will have any part of the twenty acres, ſhe muſt put her lands given in frank-marriage in hotch-pot, that is, ſhe muſt refuſe to take the ſole profits of the ten acres, but ſuffer them to be mingled with the other twenty, ſo that an equal diviſion may be made of the whole thirty between her and her ſiſter. Thus, for her ten acres ſhe will be entitled to fifteen. Coke on Litt.

This was left to the choice of the donee in frank-marriage; and if ſhe did not chuſe to put her lands into hotch-pot, ſhe was preſumed to be ſufficiently provided for, and the reſt of the inheritance was divided among her other ſiſters. The law of hotch-pot took place only, when the other lands deſcending from the anceſtor were fee-ſimple; for if they deſcended in tail, the donee in frank-marriage was entitled to her ſhare, without bringing the lands ſo given into hotch-pot. (Litt. § 274.) And the reaſon is, becauſe lands deſcending in fee-ſimple are diſtributed by the policy of law, for the maintenance of all the daughters; and if one has a ſufficient proviſion out of the ſame inheritance, equal to the reſt, it is not reaſonable that ſhe ſhould have more; but lands deſcending in tail are not diſtributed by the operation of the law, but by the deſignation of the giver, *per formam doni*, however unequal the diſtribution may be.

Alſo no lands, but ſuch as are given in frank-marriage, ſhall be brought into hotch-pot; for no others are looked upon in law as given for the advancement of the woman, or by way of marriage-portion. (Litt. 275.) But gifts in frank-marriage having fallen into diſuſe, it would have been needleſs to mention the law of hotch-pot, if this method of diviſion had not been revived and copied by the ſtatute for diſtribution of perſonal eſtates. See Frank-*Marriage*, and Custom *of London*.

HOTCH-POTCH, or Hodge-Podge, from the French *hache en poche*, or, according to Camden, *hachee en pot*, i. e. *boiled in a pot*, primarily denotes a Flemiſh medley diſh, made of fleſh cut in pieces, and ſodden with herbs, roots, &c.

HOTMAN, Francis, in *Biography*, a French civilian, was born at Paris in 1524: at the age of fifteen he was ſent to ſtudy the law at Orleans, where his progreſs was ſo rapid, that within three years he received the doctor's degree. He read lectures at Paris, but quitting the religion in which he was educated, and embracing the Proteſtant ſyſtem, he went to Switzerland, from whence he removed to Straſburg, where he obtained a profeſſorſhip of the civil law. He afterwards engaged in the ſervice of the king of Navarre, and took two journies into Germany, for the purpoſe of obtaining ſuccours from the Proteſtant princes. On his return, he removed to Valence, where his law-lectures revived the credit of the univerſity: after which he was induced to accept a profeſſorſhip at Bourges; this he ſoon reſigned, to partake in the councils of the heads of the Proteſtant party at Orleans; but at the time of the infamous maſſacre of St. Bartholomew he retired to Baſil, where he died, in the year 1590. His works were publiſhed, in 1599, in three volumes folio. He was a learned and profound juriſt, an eloquent hiſtorian, an able politician, and an ingenious man. His works conſiſt, for the moſt part, of tracts relative to the civil law, and to the Roman hiſtory and conſtitution. Bayle.

HOTOM, or Kotan, in *Geography*, a town of Little Bucharia; 230 miles S.E. of Caſhgar. N. lat. 37° 42'. E. long. 80°.

HOTORE, a town of Bengal; 22 miles E.S.E. of Doeſa.

HOTOWACZYN, a town of Lithuania, in the palatinate of Troki; 16 miles E. of Grodno.

HOTTENPLOZ, a town of Moravia, in the circle of Prerau, inſulated in Sileſia; 12 miles N.N.E. of Jagerndorf.

HOTTENTOT Cherry, in *Botany*. See Cassine.

Hottentots, *Country of*, in *Geography*, a large territory of Africa, and part of Caffraria, bounded on the N. by countries unknown, and on the S.E., S., and W. by the ſea. The coaſt is mountainous, and abounds in capes and bays. The whole country, diſtinguiſhed by this appellation, is inhabited by different tribes of Hottentots, governed by various chiefs, who have no fixed reſidence, but live in huts or portable houſes, and remove their kraals, or villages, whenever the paſture fails to ſupply their cattle, or upon the death of an inhabitant. Ever ſince the eſtabliſhment of the Dutch in the ſouthern part of Africa, they have been ſeparated and diſperſed from the neighbourhood of the Cape of Good Hope; and thoſe who from ill uſage and oppreſſion have been removed to a conſiderable diſtance, or to regions that have been inacceſſible to their purſuers, have maintained ſome ſeparate eſtabliſhments, and retained, in a degree, their primitive habits and manners. The Hottentots are divided from the Caffres or Kaffers by the Great Fiſh river. The diſpoſition and character of theſe people have been much miſrepreſented; and we are indebted principally to Mr. Barrow for a juſt account of them; who has rectified the miſtakes and confirmed the more favourable repreſentations of modern writers. Dr. Sparrman has given the following account of the Hottentots. With regard to their perſons, he ſays, they are as tall as moſt Europeans, and if they are, in general, leſs corpulent, this is owing to their being more ſtinted in their food, and to their not being accuſtomed to hard labour. But that they have ſmall hands and feet compared with the other parts of their bodies has been remarked by no one before, and may, perhaps, be regarded as a characteriſtic mark of this nation. The root of the noſe is for the moſt part very low, by which means the diſtance of the eyes from each other appears to be greater than in Europeans. The tip of the noſe likewiſe is pretty flat. The iris is ſcarcely ever of a light colour, but has a dark brown caſt, which ſometimes approaches to black. Their ſkin is of a yellowiſh-brown hue, reſembling that of an European who has the jaundice in a high degree; however, their colour is not in the leaſt obſervable in the whites of the eyes. One does not find ſuch thick lips among the Hottentots as among their neighbours the Negroes, the Caffres, and the Mozambiques. Their mouths are of a middling ſize, and almoſt always furniſhed with a ſet of the fineſt teeth that can be ſeen, and taken together with the reſt of their features, as well as their ſhape, carriage, and every motion, in ſhort their "tout enſemble," indicate health and content, or at leaſt an air of "ſans ſouci." At the ſame time, this careleſs mien diſcovers marks of alacrity and reſolution; qualities which the Hottentots can occaſionally exhibit. Their heads one would ſuppoſe, o be covered with a black, though not very cloſe, frizzled kind of wool, if the natural harſhneſs of it did not ſhew that it was hair, if poſſible, more woolly than that of the negroes. If, in other reſpects, there ſhould, by great chance, be obſerved any traces of a beard, or of hair, on any other parts of the body, ſuch as are ſeen on the Europeans, it is, however, very trifling, and generally of the ſame kind as that on the head. Dr. Sparrman refutes an opinion, which has repreſented the men as being different from others, and adds, that the women have no parts uncommon to the reſt of their ſex. With reſpect to their dreſs, and method of painting themſelves, he remarks, the latter (if painting it may be called) conſiſts in beſmearing their bodies all over moſt copiouſly with fat, in which there is mixed up a little ſoot. This is never wiped off; on the contrary, he never ſaw them uſe any thing to clean their ſkins, excepting that, when in greaſing the wheels of their waggons, their hands were beſmeared with tar and pitch, they uſed to get it off very eaſily with cow dung, at the ſame time rubbing their arms up to the ſhoulders with this coſmetic; ſo that as the duſt and other filth, together with their ſooty ointment and the ſweat of their bodies, muſt neceſſarily, though it is continually wearing off, in ſome meaſure adhere to the ſkin, it contributes not a little to conceal the natural hue of the latter, and at the ſame time to change it from a bright umber-brown to a browniſh-yellow colour, obſcured with filth and naſtineſs. Beſides the pleaſure the Hottentots find in beſmearing their bodies from head to foot, they likewiſe perfume themſelves with powder of herbs, with which they ſprinkle both their heads and bodies, rubbing it all over them when they beſmear themſelves. The odour of it is at the ſame time rank and aromatic, and ſeems to come neareſt to that of the poppy mixed with ſpices. The plants uſed for this purpoſe are different ſpecies of the Dioſma, called by the Hottentots "Bucku," and conſidered by them as poſſeſſing great virtues in curing diſorders. Some of theſe ſpecies are very common about the Cape; but one particular ſort, which grows about "Goud's-Rivier," is ſaid to be ſo valuable, that no more than a thimble full of it is given in exchange for a lamb.

The Hottentots, with their ſkins thus beſmeared with greaſe and ſoot, and Bucku-powders, are in a great meaſure defended from the influence of the air, and may in a manner reckon themſelves dreſſed. In other reſpects both men and women appear naked, excepting that a trifling covering always conceals part of their bodies. The covering of the men conſiſts of a bag or purſe made of ſkin, hanging quite open, and only faſtened by a ſmall part of its upper end to a narrow belt, ſo that it is an imperfect covering; and when the wearer of it is in motion, it is no concealment at all. This purſe is called Jackall, from the name of the animal, of whoſe ſkin it is prepared, with the hairy ſide turned outward. As another covering which decency requires the men to uſe, we may alſo conſider two leather ſtraps, generally hanging from the bottom of the chine of the back down upon the thighs, each of them being in the form of an iſoceles triangle, with the points or upper ends faſtened to the belt already mentioned, and with their baſes, about three fingers broad, hanging careleſsly down. Theſe ſtraps make a kind of rattling noiſe, as the Hottentot runs along, and probably by fanning him, produce an agreeable coolneſs. Among the Hottentots, the fair ſex appear to be the moſt modeſt, for the females cover themſelves much more ſcrupulouſly than the men, uſing for this purpoſe two, and very often three coverings, made of a prepared and well-greaſed ſkin, which are faſtened round their bodies with a thong, reſembling the aprons of European females. The outermoſt is always the largeſt, meaſuring in breadth from about 6 to 12 inches. This is frequently adorned with glaſs-beads ſtrung in different figures, thus indicating among the unpoliſhed Hottentots not only a regard to neatneſs and decorum, but powers of invention, and a diſpoſition to ſet off their perſons to the beſt advantage. The outermoſt apron reaches about half way down the thighs, and is chiefly intended for ornament. The middle one is about a third or one-half leſs, and is regarded by them as an additional entrenchment of modeſty, when their gala garment is laid aſide. The third, or innermoſt, about the ſize of one's hand, is ſaid to be uſeful at certain periods, which are much leſs troubleſome to the fair ſex here than in Europe. All theſe aprons, however, and even that which is decorated with beads, are not leſs beſmeared and greaſy than their bodies. The garment worn by the Hottentots for covering their bodies is a ſheep-ſkin, with the woolly ſide turned inwards; this peliſſe, or elſe a cloak made of ſome ſmaller fur, is tied forwards over the breaſt, and worn looſe, or wrapped round them, as far as below the knees, according to the ſtate of the weather. In general, the Hottentots do not burden themſelves with many changes of their cloaks, or "kroſſes," (as they call them in broken Dutch), but are content with one, which ſerves them both for cloathing and bedding; and in this they lie on the bare ground, covered with this kroſs or karoſs. The cloak, or karoſs, of the woman differs little from that of the men, except that their's has a little hood or pouch, with the hairy ſide inwards, in which they carry their infants, to which they now and then throw the breaſt over their ſhoulders. The men have ſeldom any peculiar covering on their heads. The women likewiſe go bare-headed: but when they uſe any covering, it is a cap in form of a truncated cone, made of ſome animal's ſtomach, and as black as ſoot, mixed with fat, can make it. Over this they ſometimes wear a kind of oval wreath, or a crown made of a buffalo's hide, with the brown hair upwards, about four fingers high, and ſurrounding the head ſo as to reach a little way down upon the forehead and the neck behind. The rims of this wreath, above and below, are ornamented with a row of ſmall ſhells of the Cypræa kind, in number about 30, and placed quite cloſe, ſo that their beautiful white enamel, together with their mouths, is turned outwards. Between theſe two rows of ſhells, there are others diſpoſed as their fancy ſuggeſts. The ears of the Hottentots are never adorned with any pendant or ornament, any more than the noſe, according to the cuſtom of other ſavages: the latter, however, is ſometimes marked with a black ſtreak of ſoot, or a large ſpot of red lead; and on high days and holidays they put ſome of the latter on their cheeks. The necks of the men are bare; but thoſe of the women are decked with an ornament, held in high eſtimation, which conſiſts of a thong of undreſſed leather, upon which are ſtrung eight or ten ſhells. Theſe ſhells are commonly ſold for not leſs than a ſheep a-piece, as it is ſaid they are procured no where elſe than on the moſt diſtant coaſt of Caffraria. On their arms and legs they wear rings, and this ornament is uſed by both ſexes. Theſe rings are made of leather ſtraps, formed in a circular ſhape. This ornament has given occaſion to the almoſt univerſally received report, that the Hottentots wrap guts about their legs, in order to eat them occaſionally. The men wear from one to five or ſix of theſe rings on their arms, but ſeldom any on their legs. Theſe rings are of various thickneſſes; and to the matrons of higher rank, who have them both on their arms and legs, they give great trouble both in the preparation and uſe of them. Rings of iron and copper, and eſpecially of braſs, of the ſize of a gooſe-quill, are conſidered as more handſome and more valuable than thoſe of leather. The girls are not allowed to wear any rings till they are marriageable. The Hottentots ſeldom wear any ſhoes: thoſe in occaſional uſe are made of undreſſed leather, with the hairy ſide outwards; which leather undergoes no other preparation beſides that of being beaten and moiſtened with cow-dung and ſome kind of greaſe. The Hottentots who live within the boundaries of the Dutch colonies ſeldom make uſe of any weapons; here and there they furniſh themſelves with javelins, as a defence againſt the wolves: theſe are called “Haſſagais.” The habitations of the Hottentots are like their dreſs, adapted to the wandering paſtoral life. They ſcarcely merit any other name than that of huts. In a Hottentot kraal or village the huts are built exactly alike, ſo that the equality of fortune and happineſs among theſe people excludes mutual jealouſy and envy. Some of theſe huts are circular, others of an oblong ſhape, reſembling a rural bee-hive or a vault. The ground plot is from 18 to 24 feet in diameter: the higheſt of them are ſo low, that even in the centre of the hut, a middle-ſized man cannot ſtand upright. The door is barely three feet high; but the Hottentot finds no difficulty in ſtooping and crawling on all fours, as he is always more inclined to lie down than to ſtand. The fire-place is in the middle of each hut, and therefore when they ſit or rather lie in a circle round the fire, the whole company equally enjoy the benefit of its warmth. The door is the only part of the hut that lets in day-light, and it is the only outlet for ſmoke. The frame of the arched roof is compoſed of ſlender rods and ſprays of trees, which, previouſly bent into a proper form, are laid, parallel to each other, or croſſ-wiſe; and theſe are ſtrengthened by binding others round them in a circular form with withies. Theſe withies, as well as the rods themſelves, are taken chiefly from the “Cliffortia conoides,” which grows plentifully in this country near the rivers. Large mats are then laid very neatly over this lattice-work, ſo as perfectly to cover the whole. The aperture of the door is cloſed when occaſion requires, with a ſkin fitted to it, or a piece of matting. The mats are made of cane or reed, faſtened together with ſinews or catgut, or ſome kind of packthread procured from the Europeans. When a Hottentot has a mind to take down his houſe and remove his dwelling, he lays all his mats, ſkins, and ſprays, on the backs of his cattle. The order or diſtribution of theſe tents in a kraal or clan is moſt frequently in the form of a circle, with the doors inwards; by theſe means a kind of yard or court is formed, where the cattle are kept at night. The milk, as ſoon as it is taken from the cow, is put to other milk which is curdled, and is kept in a leather ſack; of this the hairy ſide, being conſidered as the cleanlier, is turned inwards; ſo that the milk is never drank while it is ſweet. In certain northern diſtricts, ſuch as Roggeveld, or Bokkeveld, where the land is, as it is called, Karrow (which ſee), or dry and parched, the Hottentots, as well as the coloniſts, are ſhepherds.

From the account of the Hottentots given by Mr. Barrow it appears, that the neglect or oppreſſion with which they have been treated by the coloniſts has contributed to corrupt and degrade them. Having firſt held out the irreſiſtible charm which ſpirituous liquors and tobacco are found to poſſeſs among all people in a rude ſtate of ſociety, they took the advantage of exchanging thoſe pernicious poiſons for the only means the natives enjoyed of ſubſiſting themſelves and their families; and inſtead of inſtructing and encouraging a race of men of willing and intelligent mind to renew the means of ſubſiſtence of which they had deprived them, they imported at a vaſt expence a number of Malay ſlaves, not more expert and much leſs to be depended on than the Hottentots, to whom, indeed, they even preferred the ſtupid negroes of Moſambique and Madagaſcar. That they are capable of inſtruction and improvement, both mental and moral, appears from the laudable eſtabliſhment of the Herrnhüters or Moravian miſſionaries, who, by the protection afforded them under the Britiſh government, and its liberality, through general Dundas, in enabling them to enlarge their territory, had ſucceeded ſo far, in the object of their miſſion, as to bring together into one ſociety not fewer, at the time of the evacuation of the colony, than 600 poor Hottentots; whom they not only inſtructed in the principles of the Chriſtian religion, but by example as well as by precept taught to feel, that their value in ſociety was in proportion to the benefit they were able to render to that ſociety, by their labour and moral conduct. On the contrary, when they experienced a treatment leſs favourable than that of the meaneſt ſlaves, and were employed with a view merely to the benefit of thoſe who had poſſeſſion of their country, and were neither paid, clothed, nor fed, they exhibited on the ſame ſpot a ſcene of filth and wretchedneſs; they became a nuiſance to the town, and of courſe it became neceſſary to diſband them. Sir James Craig bears honourable teſtimony to the diſpoſition and conduct of thoſe Hottentots whom he formed into a corps. He repreſents them as contented and grateful, as intelligent and docile; no more addicted to drunkenneſs than our own people, nor invincibly diſpoſed to rove and abandon the ſervice aſſigned them. By degrees they became cleanly in their perſons; the practice of beſmearing themſelves with greaſe being entirely left off; and they frequently waſhed themſelves in a rivulet, where they could have in view no other object but cleanlineſs.

Other miſſionaries, ſays Mr. Barrow, but of different ſocieties, have lately proceeded to very diſtant parts of the colony, and ſome even much beyond it, both among the Kaffers to the eaſtward, and the Bosjeſman Hottentots to the northward: the latter they repreſent as a docile and tractable people, inexpreſſibly grateful to their benefactors; but they ſay, the Kaffers are a volatile race, extremely good humoured, and ridiculing all their attempts to convert them to Chriſtianity. A Hottentot, ſays the ſame ingenious writer, among the many good qualities he poſſeſſes, has one which he is maſter of in an eminent degree; that is, a rigid adherence to truth. When accuſed of a crime of which he has been guilty, with native ſimplicity he always ſtates the fact as it happened; but at the ſame time he is always ready with a juſtification of what he has done. From lying and ſtealing, the predominant and inſeparable vices of the condition of ſlavery, the Hottentots may be conſidered as exempt. “In the whole courſe of my travels, and in the midſt of the numerous attendants of this nation, with which I was conſtantly ſurrounded, I can with ſafety declare that I never was robbed nor deceived by any of them.” Of the ſeverity of the treatment which theſe poor people received from the ſavage boors of the country, we have many inſtances on record. We ſhall content ourſelves with mentioning only one. A young Hottentot woman, with a child in her arms, was found lying ſtretched on the ground in a moſt deplorable condition; ſhe had been cut from head to foot with one of thoſe infernal whips made of the hide of a rhinoceros or ſea-cow, known by the name of “Sambocs,” in ſuch a barbarous and unmerciful manner, that there was ſcarcely a ſpot on her whole body free from ſtripes; nor had the ſides of the little infant, in clinging to its mother, eſcaped the ſtrokes of the brutal monſter. For ſeveral days after ſhe was taken care of, there were little hopes of her recovery; though by means of a good conſtitution and tender treatment ſhe did afterwards recover. And what does the reader ſuppoſe could have been the atrocious crime that demanded ſuch chaſtiſement? The only crime alleged againſt her was the attempt to follow her huſband, who was among the number of thoſe of his countrymen that had determined to throw themſelves upon the protection of the Engliſh. A Hottentot is capable of ſtrong attachments; with a readineſs to acknowledge, he poſſeſſes the mind to feel the force of a benevolent action. "I never found," ſays Mr. Barrow, "that any little act of kindneſs or attention was thrown away upon a Hottentot; but on the contrary, I have frequently had occaſion to remark the joy that ſparkled on his countenance, whenever an opportunity occurred to enable him to diſcharge his debt of gratitude. I give full credit to all that Monſieur le Vaillant has ſaid with regard to the fidelity and attachment he experienced from this race of men; of whom the natural character and diſpoſition ſeem to approach nearer to that of the Hindus than of any other nation."

Dr. Sparrman mentions a tribe of Hottentots, called "Boſhmans," or "Boſheiſmen," who live round about Camdebo and Sneeuwberg, who are ſworn enemies to the paſtoral life, and who live on hunting and plunder. Their weapons are poiſoned arrows, which, ſhot out of a ſmall bow, will fly to the diſtance of 200 paces, and will hit a mark with a tolerable degree of certainty at the diſtance of 50 or even 100 paces. From this diſtance they can by ſtealth, as it were, kill the game they hunt for food, as well as their foes, and even ſo large and tremendous a beaſt as the lion. Their bows are hardly a yard long, and about an inch thick in the middle, and very much pointed at both ends. The ſtrings of the bows are ſinews, or a kind of hemp, or the inner bark of ſome vegetable. The arrows are a foot and a half long, made of reed, armed with a highly poliſhed bone five or ſix inches long. At the diſtance of an inch or two from the tip of this bone, a piece of quill is bound very faſt with ſinews, ſo that the arrow may not be eaſily drawn out of the fleſh, and thus the poiſon inſinuates itſelf and infects the wound. Their quivers are two feet long, and four inches in diameter. Beſides a dozen of arrows, every quiver contains a ſlender hone of ſand-ſtone for whetting the iron head, and a bruſh for laying on the poiſon. The poiſon is taken from ſeveral different kinds of ſerpents, and the more venomous they are, the better. The dwellings of theſe foes to a paſtoral life are generally not more agreeable than their manners. Like the wild beaſts, buſhes and clefts in rocks by turns ſerve them inſtead of houſes; and ſome of them are ſaid to be ſo far worſe than beaſts, that their ſoil has been found cloſe to their habitations. Many of them are entirely naked; and others cover their bodies with ſuch ſkins of animals as they are able to procure. As ignorant of agriculture as apes and monkies, like them they are obliged to wander about over hills and dales after certain wild roots, berries, and plants, which they eat raw. Their tables are ſometimes covered with the larvæ of inſects, ſnakes, and ſpiders. The capture of ſlaves from this race of men is eaſily effected. For this purpoſe, ſeveral farmers, who are in want of ſervants, join together, and take a journey to that part of the country where the Boſhieſmen live. They themſelves, as well as their Lego-Hottentots, or ſuch Boſhieſmen as have been caught ſome time before, and have been trained up to fidelity in their ſervice, endeavour to ſpy out where the wild Boſhieſmen have their haunts, which is beſt diſcovered by the ſmoke of their fires. They are found in ſocieties from 10 to 50 and 100. The farmers in a dark night ſet upon them, notwithſtanding their numbers, with ſix or eight people, having previouſly ſtationed themſelves at ſome diſtance round about the kraal. They then give the alarm by firing a gun or two. The ſavages are thus terrified; ſome of them make their eſcape by flight; others are ſtupid and timorous, and ſuffer themſelves to be captured. Theſe are treated at firſt kindly, and plentifully fed with various kinds of game; ſupplied with tobacco, and induced to accompany the coloniſt to his place of abode. Their luxurious feaſts of meat and fat are then exchanged for butter milk, frumenty, and haſty-pudding. With this change of fare, and a correſponding alteration of uſage, they very ſenſibly feel the hardſhip of their condition, and make every effort in their power to eſcape.

The language of the Hottentots is ſaid to be a compoſition of ſtrange and diſagreeable ſounds, reſembling rather the noiſe of irritated turkies, the chattering of magpies, hooting of owls, than human ſound or articulation, and depending on extraordinary vibrations, inflections, and claſhings of the tongue againſt the palate; and therefore it is no wonder that it ſhould be underſtood by few, and that the knowledge of it can ſcarcely be acquired by perſons of any other nation. As to their religion, it does not appear that they poſſeſs any, or that till of late any pains have been taken by their invaders and conquerors to afford them any inſtruction. Addicted to magic, they have among them abundance of witches and conjurers, and under bodily diſorders they run to them for relief; and as their wizards employ both internal and external remedies, they are ſometimes ſucceſsful, but they more frequently fail in adminiſtering efficacious remedies. Deſtitute, as they are ſaid to be, of any religious principles, they ſeem to have ſome ideas of a future ſtate. Some have ſaid that they worſhip a genus of inſects called "Mantis," and others have affirmed that they pay a kind of adoration to the moon; but theſe reports have not been duly authenticated. See Paterſon's Narrative of four Journies into the Country of the Hottentots, &c. 4to. 1789. Barrow's Travels in Africa, vol. i. and ii. See BOOSHOOANAS, CAFFRARIA, KAFFERS, KOUSSIS. See alſo CAPE OF GOOD HOPE.

HOTTENTOT *Holland*, a diſtrict of Southern Africa, which is a continuation of what is called the Sand Down, being a large tract of country lying between the Table bay, and bay Falſe. Moſt of it is uninhabitable, on account of a white ſand blown up by the S.E. winds in very large ridges. There are, however, many ſhrubs diſperſed in different parts. It is the principal place whence they procure their fire-wood at the Cape. This territory is ſituated on the N.E. ſide of bay Falſe, and ſurrounded on three ſides by lofty mountains; but open to the S.W. where the bay is in view. The ſoil is not ſo good for vines as moſt other places on this ſide of the mountains, being wet and marſhy; but it produces excellent corn. Here is one of the moſt difficult paſſes into the country, called "Hottentot Holland's Kloaf;" *kloaf* or *kloof* denoting a narrow paſs through the mountains. This high chain of mountains terminates the Cape iſthmus, and at a few miles to the ſouthward of the Kloof it forms the eaſtern boundary of the extenſive bay Falſe. This Kloof is a narrow road cut through the hill, the ſummit of which appears to be nearly of a height with the Table land. The chain of mountains, commencing at cape Falſe, or the Hang-Lip, extends to the N.W. for nearly 300 miles; and from 20 to 40 miles from the ſea. Several other branches from this chain extend to the interior parts of the country.

HOTTERRE, in *Biography*, born in Italy of French parents, was an excellent performer on the flute, and publiſhed an elementary work on that inſtrument that was much eſteemed. He likewiſe publiſhed another work, entitled "L'Art de Preluder," the art of preluding.

There was a Mad. Hotterre, about the year 1740, who played well on the violin.

HOTTINGER, JOHN HENRY, was born at Zurich, in Switzerland, in the year 1620. His love of learning was ſo remarkable, that he was ſent to foreign countries for education at the public expence. He viſited ſeveral parts of Europe, and at his return was made profeſſor of eccleſiaſtical hiſtory and the Oriental languages. He was appointed chaplain to the embaſſy of the ſtates-general to Conſtantinople in 1641; but the magiſtrates of Zurich would not permit him to accept of it, chooſing rather to recal him home, that his learning, talents, and zeal might be employed for the glory and advantage of their own public ſchools. He was engaged by the elector palatine to reſtore the univerſity of Heidelberg. While he was preparing for his journey to Holland, he was unfortunately drowned in the river which runs through Zurich, in conſequence of the overſetting of a boat, in which he was proceeding to an eſtate that he had at the diſtance of two leagues from that city. This event took place in 1667, when he was little more than forty-ſeven years of age. He was author of forty volumes on different ſubjects, the titles of the moſt important are given by Bayle. His ſon John James was profeſſor of theology at Zurich, and author of many practical pieces.

HOTTONIA, in *Botany*, a genus dedicated, by Boerhaave, to Peter Hotton, the predeceſſor of that illuſtrious phyſician in the botanical chair at Leyden. The ſucceſſor of Hotton did not beſtow this name upon the plant in queſtion without ſetting forth in a brief though cordial manner the virtues and qualifications of its prototype.—Boerh. Hort. Lugd. v. 1. 206. Linn. Gen. 82. Schreb. 108. Willd. Sp. Pl. v. 1. 812. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. v. 1. 226. Ait. Hort. Kew. v. 1. 197. Juſſ. 95. Lamarck Dict. v. 3. 137. Illuſtr. t. 100.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Preciæ*, Linn. *Lyſimachiæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five, linear, ſomewhat ſpreading ſegments. *Cor.* of one petal, ſalver-ſhaped; tube as long as the calyx; limb divided into five, flat, ovate-oblong, emarginate ſegments. *Stam.* Filaments five, awl-ſhaped, ſhort, erect, oppoſite to the diviſions of the corolla, and inſerted into the tube; anthers oblong. *Piſt.* Germen ſuperior, globoſe, pointed; ſtyle thread-ſhaped, ſhort; ſtigma globoſe. *Peric.* Capſule globular, pointed, of one cell, placed on the calyx. *Seeds* numerous; receptacle globoſe, large.

Eſſ. Ch. Corolla ſalver-ſhaped. Stamens inſerted into the margin of the tube oppoſite to the ſegments. Capſule of one cell. Stigma globoſe. Calyx five-cleft.

Obſ. The number of ſegments in the corolla, and conſequently of the ſtamens, is often much greater than the generic character deſcribes.

1. *H. paluſtris*. Featherfoil, or Water violet.—Linn. Sp. Pl. 208. Engl. Bot. t. 364. Curt. Lond. faſc. 1. t. 11.—" Stalk bearing many flowers in whorls."—A native of this country, found in clear ſtreams and ditches, flowering in June and July. *Root* perennial, creeping. *Stems* erect, naked, many-flowered, leafy at the baſe. *Leaves* bright-green, elegantly and deeply pinnatifid or pectinated, ſmooth, growing under water. *Spike* denſe, of ſeveral whorls, more or leſs diſtant, one above the other, riſing nearly a foot above the ſurface; partial ſtalks ſingle-flowered, bracteated. *Flowers* bluſh-coloured, with ſix, ſeven, or eight ſegments and as many ſtamens. *Capſule* globular, with many ſeeds on a globoſe receptacle.—The beauty and elegance of this plant have been very juſtly commended both by Dr. Smith in his Engliſh Botany, and Mr. Curtis in the *Flora Londinenſis;* indeed the former author ſays " that it may vie with many of the moſt admired exotics in elegance, having indeed, like ſome other European aquatics, very much the air of a tropical plant."

A very beautiful variety of this, with flowers of a deep roſe colour, was diſcovered near Kelmarſh in Northamptonſhire by the late Mr. Hanbury, F.L.S.

It appears to us that the three other ſpecies mentioned by Willdenow are at beſt very doubtful. *H. indica,* a plant concerning which the moſt intelligent botaniſts have always had doubts, becauſe of its habit, is made into a new genus under the name of *Limnophila* by Mr. R. Brown, *Prod.* v. 1. 442. We are unacquainted with the *ſerrata* of Willdenow, or the *ſeſſiliflora* of Vahl; but by their deſcriptions the former at leaſt ſeems to be a *Limnophila,* and probably the latter alſo.

HOTTS, or Hutts, pounces, and round balls of leather ſtuffed or tied on the ſharp ends of fighting-cocks' ſpurs, to keep them from hurting one another in ſparring or breathing themſelves.

HOTY, in *Geography*, a town of Sweden, in the province of Blekingen; 21 miles W. of Carlſcrona.

HOTZEMPLOTZ, a town of Moravia, inſulated in Sileſia; 20 miles N. of Troppau. N. lat. 50° 12′. E. long. 17° 35′.

HOU, a village of Egypt, on the left bank of the Nile, ſituated upon the eminence, on which, as it is ſaid, the ancient city of *Dioſpolis Parva* was built. (See Diospolis.) Rubbiſh, large bricks, and ſtones ſtill larger, the remains of a dike, and an arcade, which forms an entrance to a ſubterraneous conduit, are the ſole traces now remaining of the ancient works; 28 miles S. of Girgé. N. lat. 26° 2′. E. long. 31° 27′.

HOVA, a town of Sweden, in Weſt Gothland; 18 miles N. of Marieſtad.

HOUAC, or Houat, an iſland in the Engliſh channel, about eight miles in circumference, defended by a fort; ſeven miles N.E. of Belle-Iſle. N. lat. 47° 24′. W. long. 2° 52′.

HOUAL, or Oualo, a kingdom of Africa, ſituated on the banks of the Senegal, and on the coaſt of the Atlantic, 90 miles from E. to W., and 18 from N. to S. The ſoil is rich and fertile, producing in the greateſt abundance maize, rice, indigo, tobacco, and cotton; the meadows feed a great number of cattle, large and ſmall, whoſe fleſh is excellent; game is plentiful; birds are numerous and various; and the foreſts abound with palm-trees. The king of the country aſſumes the title of " brak" or emperor; and was formerly very powerful, but of late is reduced to a low ſtate, being frequently in want of millet for his ſupport. When he is occaſionally rouſed from his natural indolence, he aſſembles his courtiers, travels with them through the villages of his kingdom, eats the proviſions which he can find; drives away the cattle, and expoſes the owners to public ſale.

HOUARD de la Mothe, Antony, in *Biography*, a law antiquary, was born at Dieppe in 1725, and died at Abbeville in 1803. He was member of the Academy of Inſcriptions, and an aſſociate of the National Inſtitute. His works are, 1. " Anciennes Lois des François, conſervées dans les Coûtumes Angloiſes," two vols. 4to. 2. " Traité ſur les Coûtumes Anglo-Normandes, &c." four vols. 4to.

HOVAREIN, in *Geography*, a town of the deſert of Syria; 70 miles S.W. of Palmyra.

HOUBIGANT, Charles Francis, in *Biography*, was born at Paris in 1686, was educated for the church, and became a prieſt of the Oratory. He diſtinguiſhed himſelf for his profound knowledge of the Hebrew ſcriptures, which he tranſlated into the Latin language with notes, publiſhed at Paris in 4 vols. folio 1753. He died in 1783. He was author of many other pieces, among which are " A

Dictionary, French and Hebrew," 8vo.; "Examination of the Pſalter of the Capuchins;" and "A Tranſlation of biſhop Sherlock's Sermons."

HOUCHONG, in *Geography*, a town of Meckley; 18 miles W. of Munnypour.

HOUDAIN, a town of France, in the department of the ſtraits of Calais, and chief place of a canton, in the diſtrict of Bethune; ſix miles S. of Bethune. The place contains 1000, and the canton 13,603 inhabitants, on a territory of 220 kiliometres, in 31 communes.

HOUDAN, a town of France, in the department of the Seine and Oiſe, and chief place of a canton, in the diſtrict of Mantes; 10 miles S. of Mantes. The place contains 1700, and the canton 12,392 inhabitants, on a territory of 232½ kiliometres, in 31 communes.

Houdan, a ſmall iſland on the North ſea, near the coaſt of Norway. N. lat. 61° 40′.

HOVE, in *Rural Economy*, a term employed to denote the riſing or ſwelling which ſometimes takes place in cheeſes, ſoon after they are made, in conſequence of their taking on a ſlight degree of fermentation. The chief remedy in this caſe is the frequent turning of ſuch cheeſes in order to get them dry as expeditiouſly as poſſible. See Cheese and Dairying.

The term is likewiſe applied to the peculiar ſwelling in neat cattle and ſheep, which proceeds from the feeding too greedily upon ſome ſort of luxuriant green food, ſuch as red clover, &c. See Hoven.

Hove, in *Geography*, a town of Norway, in the dioceſe of Drontheim; 25 miles N.W. of Drontheim.

HOUEILLES, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the diſtrict of Nerac; ſeven miles S. of Caſtel-Jaloux. The place contains 607, and the canton 4001 inhabitants, on a territory of 335 kiliometres, in nine communes.

HOVEL, a town of Weſtphalia, in the biſhopric of Paderborn; ſix miles N.W. of Lippſpring.

Hovel, in *Rural Economy*, the name of a kind of ſhed or low building, which has ſome part of it conſtantly open below; but which is covered above. It is uſeful for young animals of the horſe, neat cattle and ſheep kinds to run into, as there may be occaſion, for protection, during the ſtormy winter months.

HOVELLING, in *Architecture*, is a method of working up the ſides of a chimney, and covering the top with tiles or bricks, ſet up in a pyramidical form, ſo that the ſmoke may eſcape below the current, when the wind makes over the chimney, or againſt any one ſide of it. This is uſed to prevent the inconvenience ariſing from adjoining buildings higher than the chimney, or from its being in the eddy of any very lofty building, or in the vicinity of high trees: the covered ſide muſt in this caſe be kept towards the building which occaſions the inconvenience.

HOVEN, in *Rural Economy*, a term applied to a peculiar ſort of diſtention or ſwelling taking place in the ſtomachs of neat cattle, ſheep, and ſome other animals, in conſequence of the ſudden extrication of air, proceeding from the decompoſition of green ſucculent food, which they have conſumed too greedily and in too large quantities; ſuch, for inſtance, as red clover, fog, or rank-graſs, &c. See Clover.

In this caſe, the chief remedy is evidently the diſcharge of the confined air from the ſtomach of the animal; which in ſlight affections may be often accompliſhed by the uſe of ſuch ſubſtances as have a tendency to retard or ſtop the progreſs of the fermentative proceſs, or to force off the *flatus*. Much benefit in theſe intentions has been obtained from the giving of large doſes of prepared ammonia in mixture with ſome ſort of ſpirituous liquor; and other ſimilar remedies.

This affection has been ſuppoſed, in an able paper in the twenty-ninth volume of Young's Annals, to principally proceed from the diſtention of the firſt ſtomach of the animals by the carbonic acid gas or fixed air that is diſengaged from ſuch tender juicy graſſes, by their decompoſition; the after diſcharge of it by the gullet being prevented by ſome ſort of contraction occurring about the upper orifice of the ſtomach. It is added that the dangerous and frequently fatal effects that ſucceed the diſtention are not to be aſcribed to the air, or juices of the fermented graſs, acting as poiſons upon the ſtomach, for moderate quantities of either of them produce no bad effects: beſides, the reiterated experience of the grazier has clearly ſhewn, that cattle, in many inſtances, are immediately relieved and preſerved by the properly ſtabbing them with a ſharp-pointed knife, and letting the air eſcape in that way. It is, of courſe, concluded, that cattle may be ſaved with certainty, if the air be drawn off in due time, without injuring the ſtomach or bowels. This is ſuggeſted as capable of being done with facility, by paſſing a flexible tube through the gullet into the ſtomach. A tube of iron wire is adviſed as the moſt proper for the purpoſe, which has about one-ſixteenth of an inch diameter, and formed by twiſting it round a ſmooth iron rod three-eighths of an inch in diameter; being afterwards covered with ſmooth leather. That end of the tube which is to be paſſed into the ſtomach, ſhould have a braſs pipe of the ſame ſize, or rather larger, and two inches in length, firmly faſtened to it, and pierced with large holes in ſufficient number. In order to prevent the too much bending of the tube in the mouth or gullet in paſſing it down, an iron wire one-eighth of an inch in diameter, and of equal length with the tube, ſhould be introduced into it; being withdrawn upon the tube entering the ſtomach. It is found, that the ſpace from the fore teeth, to the bottom of the firſt ſtomach of a large ſized ox, is about ſix feet; and a tube five feet nine inches in length has been paſſed into the gullet of a living ox. A proper tube ſhould conſequently be ſix feet in length to ſucceed perfectly in all caſes. When the tube has been thus introduced it may remain for any length of time, as it does not inconvenience the breathing of the animal. By means of this tube, moſt part of the elaſtic and condenſed air may be diſcharged from the ſtomach; and where neceſſary, ardent ſpirits, or any other fluid proper for checking fermentation, be thrown through it into the ſtomach. In this way, the air is not only more certainly diſcharged than by the practice of ſtabbing, but the danger which it cauſes is obviated; this danger does not ariſe ſo much from the irritation of the wound, as the air, and other contents of the ſtomach inſinuating themſelves into the cavity of the belly, betwixt the containing parts and the bowels, and thereby creating ſuch a ſtate of inflammation as may prove fatal to the animal.

This tube is equally applicable to ſheep, when properly adapted in ſize; and not leſs beneficial in the removal of the affection. It is perfectly ſimple, and readily conſtructed by any common workman. Such tubes are however ſold, ready for uſe, in London and other places.

Wooden tubes, ſomewhat of this nature, have been contrived, and brought forward under the encouragement of the Society of Arts, by Mr. Eager, for the purpoſe of removing this ſort of diſtention in the ſtomachs of animals. They conſiſt of knobs of wood firmly attached to portions of cane of different lengths, for ſuiting different ſorts of animals, repreſentations of which may be ſeen in the annexed plate,

plate. It is directed by the inventor, that ſuch beaſts as are hoven, or ſwollen, ſhould be laid hold of by a perſon by the noſtril and one horn, while with one hand an aſſiſtant ſteadily ſecures the tongue, and with the other puſhes the cane quite down into the ſtomach. Care ſhould be had, not to let the animal get the knob of the tube between his grinders. Some reſiſtance is generally afforded to the tube about the entrance of the ſtomach, which requires a little additional force in paſſing it; as ſoon as a fœtid ſmell is found to be diſcharged, and the ſize of the body of the animal to be diminiſhed, nothing further is requiſite, as nature will effect the reſt. The ſucceſs of this method has been fully confirmed by different ſtock-farmers.

The common practice of attempting the removal of this affection by the making an inciſion or puncture by means of a pen-knife between the ſhort ribs, and fixing a pipe of ſome ſort in it to afford paſſage to the confined air, ſecuring the whole by adheſive plaiſter from the effects of the atmoſphere, is generally the reſult of real neceſſity, but often liable to be attended with fatal conſequences, from the want of knowledge, or inexpertneſs of the perſon who performs the operation. In order to ſucceed, it ſhould be done on the left ſide, about the mid-way between the ſhort ribs and the hip-bone, a long ſlender knife being employed for the purpoſe, and thruſt to the depth of from four to five inches. The operation is ſometimes denominated *paunching*, and ſhould be always carefully executed.

Oily remedies have likewiſe been had recourſe to in the view of removing theſe ſorts of ſwellings in the ſtomachs of animals; ſuch as olive oil, and butter, or lard, melted and blended together, but they can ſeldom be much depended upon, though aſſerted to produce relief in a ſpeedy manner by ſome.

It is a good method to prevent the diſeaſe taking place as much as poſſible, by properly managing the ſtock in firſt turning them upon ſuch luxuriant paſtures. This ſhould be done, when they are the leaſt preſſed by hunger, in order that they may be the ſooneſt ſatisfied with food; and when there is the leaſt dew upon the graſſes. It is alſo a good practice, in this view, to only let the animals remain a ſhort time at once upon ſuch paſtures; and ſome adviſe their being frequently driven about in them; though much injury muſt neceſſarily be done to the graſs in this way. See CLOVER.

HOVEDEN, ROGER DE, in *Biography*, an Engliſh hiſtorian, who flouriſhed in the reign of Henry II. was born at York. Having received an education ſuitable to the purpoſe, he became a profeſſor of theology at Oxford. He was likewiſe a lawyer, and is ſaid to have ſerved the king in the capacity of chaplain, and alſo in other confidential offices. It was not till the death of Henry that he applied himſelf particularly to the compilation of Engliſh hiſtory. He wrote in the Latin language, commencing his annals with the year 731, the period at which Bede finiſhes, and coming down to the third year of John, A.D. 1201. His work was printed at London in 1595, in ſir Henry Saville's "Collection of ancient Engliſh Hiſtorians," and at Frankfort in 1601. Of ſo much authority was it that Edward I. cauſed ſtrict ſearch to be made in all the libraries for copies of it, in order to aſcertain the homage due to the crown of Scotland.

HOVENIA, in *Botany*, ſo named by Thunberg, in compliment to one of the patrons of his expedition to Japan, David ten Hoven, a ſenator of Amſterdam.—Thunb. Nov. Gen. 7. Japon. 7. Schreb. 148. Willd. Sp. Pl. v. 1. 1141. Mart. Mill. Dict. v. 2. Juſſ. 381. Lamarck. Illuſtr. t. 131.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Dumoſæ*, Linn. *Rhamni*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, hairy at the baſe within-ſide, permanent; its border in five deep, ovate, reflexed, deciduous ſegments. *Cor.* Petals five, inſerted betwixt the ſegments of the calyx, and equal to them in length, obovate, very obtuſe, convoluted, enfolding the ſtamens. *Stam.* Filaments five, inſerted into the baſe of the calyx, and ſhorter than its border; anthers roundiſh, concealed by the petals. *Piſt.* Germen ſuperior, roundiſh; ſtyle erect, much ſhorter than the calyx; ſtigmas three, obtuſe, ſpreading, a little reflexed. *Peric.* Capſule globoſe, ſlightly ovate, with three furrows, three valves, and three cells. *Seeds* ſolitary, lenticular, very ſmooth.

Obſ. Sometimes, though rarely, the flowers are four-cleft and tetrandrous.

Eſſ. Ch. Calyx with five deep deciduous teeth. Petals five, convoluted. Stigmas three. Capſule ſuperior, with three valves and three cells. Seeds ſolitary.

1. H. *dulcis*. Thunb. Jap. 101. (Sicku, vulgò Ken, and Kenpokonas; Kæmpf. Amœn. Exot. 808. t. 809.) A *tree*, reſembling a middle-ſized pear-tree, found near Nagaſaki in Japan, flowering from June to Auguſt, and ripening fruit in November and December. The *branches* are round, ſmooth, ſomewhat zig-zag. *Leaves* alternate, ſtalked, ovate, pointed, finely ſerrated, ſmooth, with a ſtrong mid-rib, two ſmaller lateral ones, and many veins. *Flowers* ſmall, white, in forked, terminal or axillary, panicles, whoſe ſtalks, after the flowers fade, become very remarkably juicy, with a ſweet red fleſh, which is eaten by the Japaneſe, and compared by Thunberg to the taſte of a pear. The partial *flower-ſtalks*, immediately under the calyx, remain unchanged and ſlender, ſuſtaining the drooping *capſules*, which are the ſize of a pepper-corn, with red *ſeeds*.

HOVER GROUND, in *Agriculture*, a term applied in many diſtricts to land which has a light friable ſoil.

HOUFFALIZE, in *Geography*, a town of France, in the department of the Foreſts, and chief place of a canton, in the diſtrict of Neufchateau, ſeated on on a ſmall river which runs into the Ourte; 30 miles S. of Liege. The place contains 759, and the canton 6266 inhabitants, on a territory of 250 kiliometres, in 16 communes.

HOUGH, JOHN, in *Biography*, an Engliſh prelate, was born in the year 1650. He received his claſſical education at the ſchool of Birmingham, whence he was ſent to Oxford, where he was elected a demy at Magdalen college in 1669. Here he took his degrees, and afterwards became fellow of his college. In 1676 he proceeded M.A. and having entered into holy orders, officiated ſome time at North Aſton, in the dioceſe of Oxford. In 1681 he accompanied the duke of Ormond to Ireland, from whence he returned the following year, and in 1685 he was appointed prebendary of Worceſter, which promotion was ſoon followed by his preſentation to the rectory of Ternsford, in Bedfordſhire. In 1687 he made a firm ſtand againſt James II.'s arbitrary attempt to impoſe a preſident upon his college. By his noble example the fellows were encouraged to reject his majeſty's mandamus in favour of Antony Farmer, a convert to the Popiſh religion; they made choice of Mr. Hough to that office; and as a majority concurred in electing him, he had ſpirit enough to accept it, in defiance of the royal order. His election was regularly confirmed by the biſhop of Wincheſter, viſitor of the college; and in the ſame year he was admitted to the degree of doctor of divinity. This bold ſtep of Dr. Hough may be regarded as the commencement of that clerical reſiſtance to the tyrannical proceedings of king James, which contributed not a little to bring about the revolution. The worthy doctor was, however, almoſt inſtantly deprived of his preſidentſhip, by the order

order of James, who commanded the commiſſioners to inſtal Dr. Parker, biſhop of Oxford, in his room. Twenty-five of the fellows refuſed to ſign a ſubmiſſion to their new preſident, who, on that account, were, with Dr. Hough, expelled the college, and declared incapable of being admitted to any eccleſiaſtical dignity or benefice. In the following year, the prince of Orange's declaration was received in England, and the king, with the hope of regaining the affections of the clergy, thought it prudent to recede from his illegal and arbitrary proceedings. An order was accordingly paſſed to reſtore Magdalen college to its rights; and Dr. Hough was replaced in his preſidentſhip by a commiſſion for that purpoſe, directed by the king himſelf to the viſitor. After the revolution, Dr. Hough was nominated by king William to the biſhopric of Oxford, with which he was allowed to hold the preſidentſhip in commendam; in 1699 he was tranſlated from the ſee of Oxford to that of Litchfield and Coventry; and in 1715 he was offered the archbiſhopric of Canterbury, which, through diffidence in himſelf, he declined. In 1717 he was raiſed to the ſee of Worceſter; and, notwithſtanding he was then 67 years of age, he preſided over Worceſter 26 years, conſtantly reſiding in his dioceſe, and diſcharging with fidelity and zeal all the epiſcopal functions. He died in 1743, without pain or ſickneſs, but quite exhauſted, full of days and honour. He was a very munificent prelate, and expended on his epiſcopal palaces upwards of 7000*l.* His private benefactions were very extenſive, and his hoſpitality ſuch as became his ſtation as a father of his people. Biog. Brit.

Hough, in *Animals*, the name of the bending or ply of the hind leg, which alſo compriſes the part behind but oppoſite to the ply, uſually denominated the *hock*. This point or part, in the horſe, ſhould be full, and not too crooked, in order to conſtitute a well formed leg.

To Hough, *or cut the houghs*, is to ham-ſtring, or to diſable by cutting the ſinews of the ham.

Hough, *Bony*, is a hard, round ſwelling, or tumour, growing upon the tip or elbow of the hough.

It generally proceeds from ſome ſtroke or bruiſe; and if neglected till the ſubſtance of the ſwelling becomes hard, like glue, it proves difficult to cure.

Hough, in *Nautical Affairs*, is a name for the ſquare head of ſome ſorts of barges, thoſe, for inſtance, which are uſed for carrying coals on the Thames, at London.

HOULIERES, Antoniette du Liger de la Garde, des, in *Biography*, a diſtinguiſhed French poeteſs, was born at Paris in 1638. Her talents for writing French verſe were firſt excited and cultivated by the preſident Henault. She married Lafon ſeigneur des Houlieres, ſoon after which ſhe was arreſted at Bruſſels by order of the Spaniſh government, and carried as a priſoner of ſtate to the caſtle of Wilvorden, from thence ſhe was releaſed through the artifice of her huſband. She came to Paris, and attracted round her a circle of admirers and men of wit. Becoming a widow ſhe fell into indigent circumſtances. At length ſhe obtained a ſmall penſion, and ſolaced herſelf with ſtudy, and acquired the knowledge of the Latin, Italian, and Spaniſh languages, the beſt authors in which ſhe read with facility. She died in 1694. Her poems were collected in two volumes in 1724, and reprinted in 1747, in two volumes 12mo. They conſiſt of idylls, eclogues, odes, epigrams, and the tragedy of Genſeric. The idylls are accounted the beſt compoſitions of the claſs in the French language. She has been charged with groſs plagiariſm.

HOULLIER. See Hollerius.

HOUMA, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia; 21 miles S.E. of Kara-hiſer.

HOUMIRI, in *Botany*, Aublet. Guian. v. 1. 564. t. 225. (Houmiria; Juſſ. 435.) Red-gum tree, or Red wood, of Guiana. See Myrodendrum.

HOUN, in *Geography*, a town of Africa, in Fezzan; 10 miles S. of Wadan.

HOUNA, a cape and village of Scotland, on the N. coaſt of the county of Caithneſs; two miles W. of Duncanſby Head. N. lat. 58° 33′. W. long. 2° 57′.

HOUND, *canis venaticus*, a hunting-dog. See Dog.

Hounds may be diſtinguiſhed, with regard to the manner of their hunting, into ſuch as find out and purſue the game by ſight, and the quickneſs and ſwiftneſs of their motion; of which kind are the *gaze-hound, agaſæus;* and *grey-hound, canis graius;* the *terrier*, &c. And thoſe which find and purſue the game by the goodneſs of their ſmell.

The ſpecies of ſcenting-dogs may be divided further; into *hounds*, ſimply ſo called, and *blood-hounds;* each whereof admits of ſome diverſities.

1. As to *hounds*, ſimply thus called, thoſe which are all of one colour, as white, black, &c. are moſt valued; then thoſe ſpotted with red; the white with black ears, and a black ſpot at the ſetting on of the tail, are generally eſteemed the beſt for compoſing a kennel, and are of the beſt ſcent and condition; thoſe ſpotted with dun are leſs prized, as uſually wanting courage and boldneſs. The black-tanned, or the all liver-coloured, or all white, the true talbots, are beſt for the ſtring or line; and the grizzled, whether mixed or unmixed, if their hairs are ſhagged, are uſually the beſt runners. There ſhould always be a couple of theſe in the pack. *Fallow-hounds* are of good ſcent, and hardy, not fearing the water; they keep the chace well, without change; but are not ſo ſwift as the white; they love the hart above any other chace, having little ſtomach for the hare, &c. whence they are not ſo fit for private gentlemen; beſides that, they are apt to run at tame beaſts.

The *dun hounds* are of a more general uſe, being fit for all chaces. Their ſagacity and fidelity in knowing and ſticking to their maſter's voice and horn, and to none elſe, are much admired; they alſo underſtand each other, and know which are babblers, which liars, &c. They are of different ſizes and qualities in the ſeveral countries, &c. Mountainous and woodland parts breed a tall heavy ſort, called *ſlow-hounds;* moderate ſoils, where the champain and covert ſhare pretty equally, produce a middle-ſized hound of a nimbler make. The ancients laid a greater ſtreſs on colour than the moderns, with whom it is a kind of fixed opinion, that the colour of a good hound, or a good horſe, is unimportant.

The marks of a good and fair hound are to be of a middle proportion, rather long than round, the noſtrils wide, back bowed, fillets great, haunches large, ham ſtraight, tail big near the reins, and the reſt ſlender to the end, the leg big, the ſole dry, and claws large. See Dog.

The legs of a good fox-hound, ſays Mr. Daniel in his "Rural Sports," ſhould be ſtraight as arrows; his feet round, and not too large; his ſhoulders ſhould lie back; his breaſt rather wide than narrow; his cheſt deep; his back broad; his neck thin; his head ſmall; his tail thick and buſhy; and if he carries it well, this circumſtance will add to his comelineſs. Although a ſmall head is mentioned as one of the requiſites of a fox-hound, this is to be underſtood merely in its relation to beauty: for as to goodneſs, large-headed hounds are in no reſpect inferior. The middle-ſized hounds are reckoned the ſtrongeſt and beſt able to endure fatigue. With regard to their ſhape, it is preſumed that they muſt all agree: and in order to exhibit a good appearance, they ſhould be nearly of a ſize; if they appear of the ſame family it will be an addition, and if they are alſo handſome, they are deemed perfect as far as appearance is concerned. It is of great importance in the ſhape of a hound that it ſhould exhibit a perfect ſymmetry: for if this be not the caſe, he will neither run faſt nor bear hard work; much ſpeed is required, and he ſhould poſſeſs adequate ſtrength. A prepoſſeſſion will always occur in favour of that ſort of hound to which the ſportſmen have been moſt accuſtomed: thoſe who have uſually hunted with the ſharp-noſed, will hardly allow a large-headed hound to be a fox-hound, although both are equally ſo. Speed and beauty are the chief excellencies of the former; whilſt ſtoutneſs and tenderneſs of noſe in hunting characterize the latter. Very good ſport may be had with unſeemly hounds, where a great difference in ſize and look is apparent, but a gentleman, anxious that his hounds ſhould be complete, will not be ſatisfied with ſuch a pack: hounds ſhould run well together, and this cannot ſo well be attained as by uniting as early as poſſible, thoſe of the ſame ſort, ſize, and ſhape. Packs conſiſting of various kinds of hounds ſeldom run well together, although they may frequently kill their fox; but it is the "ſtyle" of killing which conſtitutes celebrity among ſportſmen. The great excellence in a pack of fox-hounds is the "head" they carry, conſidered in a collective body: they go faſt in proportion to the excellence of their noſes and the head they carry, and that pack may be ſaid to go the faſteſt, which can run ten miles the ſooneſt, notwithſtanding the hounds, ſeparately, may not be ſo ſpeedy as many others. Some hounds creep through the ſame hole, inſtead of *topping* the fence, and follow one another in a ſtring, as true as a team of cart-horſes. Mr. Beckford, with conciſeneſs and neatneſs, has deſcribed in what manner they ought to be "like the horſes of the Sun, *all abreaſt.*" Five and twenty couple of hounds are ſufficient at any time to be taken into the field, as being a match for any fox, ſuppoſing them ſteady, and their ſpeed nearly equal. Too many hounds always do more miſchief than ſervice. When packs are very extenſive, the hounds are ſeldom ſufficiently hunted to be good. Where many hounds are kept, either a large pack muſt be taken out, or a great number of hounds be left behind: in the firſt caſe, too many hounds in the field will probably ſpoil the diverſion, and, ſecondly, hounds long idle, always get out of wind, and not unfrequently become riotous. Forty couple of hunting hounds will admit of hunting three times a week, twenty-five couple being the uſual allotment for the field. Hounds to be ſteady muſt be conſtantly hunted: young ones in particular ſhould never be left at home while able to hunt: the lame, the old, thoſe low in fleſh, and ſuch as idleneſs cannot injure, may be ſuffered to remain quiet. Hounds that are meant to run well together, ſhould never have too many old hounds amongſt them; five or ſix ſeaſons generally deſtroying their ſpeed.

The *breeding* of hounds is an object of great importance. In reſpect of the breed of hounds, no country equals our own; and it is remarkable, that the hounds procured from England ſhould degenerate in another climate. In order to preſerve this ſuperiority, the ſize, ſhape, colour, conſtitution, and natural diſpoſition, as well as the fineneſs of the noſe, the ſtoutneſs and method of hunting of the dog, from which the breed is taken, ſhould be duly conſidered.

Nothing is more eſſential to the having a good pack of hounds, than a proper care of the whelps, and of the parents from which they are to be bred.

The bitches, in particular, ſhould be carefully choſen, and ſhould be ſuch as are the ſtrongeſt and beſt proportioned; they muſt alſo have large ribs and flanks.

The beſt ſeaſon for the coupling of hounds is in January, February, or March; for then they will litter in a good time of the year, that is, in ſpring; ſo that they will be fit to enter in due courſe, without loſs of time, or of the ſeaſon; for if bitches litter in winter, it is very difficult to bring up the whelps, the cold killing them if there is not great care taken of them. If poſſible, have no whelps later than April, as late puppies ſeldom thrive. Of the early ones five or ſix ſhould be kept; of the late ones, not more than half the number.

The dogs that line the bitches muſt not be above five years old; for if they are older than this, the young ones will be dull and heavy. Care ſhould be taken to have a proper dog ready the firſt time of the bitch's going proud; for it is affirmed by many, who ſay they have experience for it, that whatever kind of dog lines a bitch the firſt time, there will be one puppy at leaſt in all her ſucceeding litters that will have ſome reſemblance of him.

On no account breed from a hound that is not ſtout, that is not tender-noſed, or that is either a babler or a ſkirter. Babling is one of the worſt faults of which a hound can be guilty; and ſkirting hounds, where game is plentiful, are always changing, and occaſion the loſs of more foxes than they kill. It is the judicious *croſs* that renders the pack complete: the imperfection on one ſide may be rectified on the other, and if this be attended to, and a croſs hit found, purſue it. The breeding from young dog-hounds after the firſt ſeaſon, who have beauty and goodneſs to recommend them, to ſee what whelps they get, is a proper trial. Never put an old dog to an old bitch, and take care that thoſe from which you breed be in good health. In breeding, the beſt bitches ſhould be ſent to the beſt dogs, wherever they may be; and thus thoſe who breed only a few hounds may have a good pack, whilſt thoſe who breed many, (if at the ſame time they underſtand the buſineſs,) reduce it to a certainty.

The firſt litter of puppies that a bitch brings, are never eſteemed ſo good as the ſecond or third. When a bitch has been lined, and grows big with whelps, ſhe is not to be ſuffered to hunt among the pack, nor to take any other violent exerciſe; for that would endanger her caſting her whelps; ſhe ſhould be kept up and fed well, and a good place ſhould be provided for her to litter in.

As ſoon as ſhe has littered, thoſe which are intended to be kept, ſhould be ſelected out, and the reſt immediately drowned. There is great difficulty in chooſing the beſt at this early time; but the general opinion gives it for thoſe which are the lighteſt, that they will be the ſwifteſt and beſt as they grow up.

Others take all the whelps away; and having determined what number they will keep, they ſettle the choice on thoſe which the bitch carries back firſt to the place where ſhe littered. But all this ſeems very uncertain. Others ſelect that which was pupped laſt.

Should one bitch have more whelps than ſhe can rear, ſome of them may be put to another bitch, and thus a favourite ſort may be preſerved. In like manner, if only one or two are produced, by ſhifting thoſe puppies to another bitch, the former will be ſoon fit to hunt again: but ſhe ſhould be firſt phyſicked, and her dugs waſhed with brandy and water. Should the bitch refuſe to take the ſtrange puppies, by killing one of her own, and rubbing the ſtrangers with a little of the blood, ſhe will lick and immediately receive them. The bitches ſhould be well fed with fleſh, and have alſo plenty of milk, nor ſhould the puppies be taken from them till they are able to feed themſelves. When the puppies are taken away, the bitches ſhould have three purging balls given them, one every other morning, and plenty of whey the intermediate day.

The whelps muſt have good freſh ſtraw to lie in, and it muſt be often changed. They are to be kept in a place where neither the rain nor ſun-ſhine can be troubleſome to them; and once a week it will be proper to anoint them all over with a little nut-oil, with ſome ſaffron infuſed in it. This will prevent the flies from annoying them ſo much as they otherwiſe would, and will kill worms of all kinds. When they are fifteen days old, it is the cuſtom to worm them, and a week after one joint of their ſtern ſhould be twiſted off. As ſoon as they can ſee, they ſhould have milk given them to lap; and at ſix weeks or two months old they muſt be weaned, keeping them wholly from the bitch; they muſt at this time be well kept, but not too high fed; and it is proper to put ſome cumin ſeed into their food, to keep the wind out of their bellies.

Many let the whelps of their hounds ſuck three months, and then ſend them away to villages to be bred up till they are ten months old, cautioning thoſe people who have the care of them, not to let them eat carrion, nor frequent warrens.

Rye-bread is a very common food for young hounds, and is particularly recommended by many, but wrongly; for it ſoon paſſes through them, and gives them very little nouriſhment. When they are fed conſtantly with this, in the time of their growing up, they always become narrow-backed; and this is a great fault in this ſort of dog; a broad back being one of the greateſt recommendations in a hound. Wheat-bread is greatly preferable on all accounts for the food of the young hound, giving him ſtrength and firmneſs.

At ten months old they are to be taken home, and put into the company of the others, to live as they do, and after a few weeks keeping company with the reſt, they are to be coupled, and to go out to hunt.

Hounds are commonly named when firſt put out, and the uſual mode is to name all the whelps of one litter with the ſame initial letter as that of the dog that got them, or the bitch who bred them. Young hounds ſhould be marked in the ſide (which is termed *branding* them) with the initial letter of their owner's name; and this will prevent their being ſtolen, or facilitate the recovery of them when they are loſt. Young hounds ought to be fed twice a day, morning and evening. It is adviſable not to round them till they are well ſettled in the kennel, nor in very hot weather, leſt they bleed too freely. It may perhaps be better to round them, whilſt at walk, when about ſix months old; if it were done ſooner, it would make their ears tuck up. They ſhould not be rounded whilſt they have the diſtemper, as the loſs of blood would too much weaken them. (See *Diſeaſes of* Dogs.) If any of the young dogs be thin over the back, or more quarrelſome than others, it will be of uſe to cut them. Such bitches alſo as are ill loined, and that are not wanted for the purpoſe of breeding, ſhould be ſpayed: they are then conſtantly ſerviceable, ſtouter, and always in better order. Beſides, if a pack hunt late in the ſpring, it will be very ſhort without hounds of the above deſcription. The operation ſhould be performed by a perſon of ſkill. There is a difference of opinion whether a bitch ſhould be ſpayed *before* or *after* ſhe has had a litter of puppies; both periods have anſwered: the beſt time is 14 or 15 days after ſhe has taken the dog, and when the puppies juſt begin to be knotted within her: all the roots of the veins ſhould not be taken away, as her ſtrength and ſwiftneſs will be injured by ſo doing: they ſhould be kept low for ſeveral days *before* the operation is performed, and fed on thin meat for ſome time *after*.

For the method of entering young hounds, ſee Entrance. For the terms uſed with reſpect to hounds, their noiſes, &c. ſee Hunting.

The hounds moſtly uſed for hare-hunting are the deep-tongued, thick-lipped, broad and long-hung ſouthern hounds: the fleet ſharp-noſed dog, ears narrow, deep-cheſted, with thin ſhoulders, ſhewing a quarter croſs of the fox-hound: the rough wire-haired hound, thick quartered, well hung, and not too much fleſh on his ſhoulders: and the rough or ſmooth beagle. Each of theſe ſorts has its excellencies, nor can one be juſtly commended as ſuperior to the other; the preference muſt depend on the prevalent inclination of the ſportſman.

He that delights in a ſix hours chace, and to be up with the dogs all the time, ſhould breed from the Southern hounds firſt mentioned, or from that heavy ſort which gentlemen uſe in the weald of Suſſex; their cry is a good and deep baſs muſic, and conſidering how dirty the country is, the diverſion they afford to thoſe who are on foot for a day together, renders them in high eſtimation; they generally pack well from their equality of ſpeed, and at the leaſt default, every noſe is upon the ground in an inſtant to recover the ſcent.

In an open country, where there is good riding, the ſecond ſort is to be preferred; their tongues are harmonious, and at the ſame time they go ſo faſt, as to prevent a hare from playing many tricks before them; they ſeldom allow her time to loiter and make much work; ſhe muſt run and continue her foiling, or change her ground; if the latter ſhe is ſoon killed, for freſh ground, eſpecially on turf, is, in ſome degree, one continued view. It is difficult, however, to procure a pack of faſt hounds that run evenly together; ſome are uſually found to tail, and their exertions to keep up to the leading hounds, make them of little uſe, farther than enlarging the cry, unleſs when the ſcent is over-run, then hounds thrown out or tailed, often come up, and hit off the fault.

It is very common for the fleeteſt hound to be the greateſt favourite, but let a hound be ever ſo good in his own nature, his excellence is obſcured in that pack which is too ſlow for him. At moſt times there is work enough for every hound in the field, and each ought to bear a part; but this it is impoſſible for the heavy hounds to do, if run out of wind by the diſproportionate ſpeed of a leading hound; for it is not ſufficient for hounds to run up, which a good hound will labour hard for, but they ſhould be able to do ſo with eaſe, with retention of breath and ſpirits, and with their tongues at command; it can never be expected that any ſcent can be well followed by hounds that do not carry a *good head*. It is too frequent a practice in numerous kennels, to keep ſome for their muſic, others for their beauty, who at beſt are ſilly and trifling, without noſe or ſagacity; this is wrong, for it is a certain maxim, that every dog which does no good, ſerves only to foil the ground and confound the ſcent, by ſcampering before or interrupting their betters in the moſt difficult points. Five couple of truſty hounds will do more execution than thirty where half of them are eager and head-ſtrong.

The third ſort are ſcarce, and an entire kennel of them ſeldom ſeen; they are of Northern breed, and by many eſteemed for the chace of the otter and marten, and in ſome places are encouraged for that of the fox; but they are bad to breed from, being ſubject to produce thick, heavy-ſhouldered dogs unfit for the chace. See Beagle.

In the choice of a hound the dog of a middling ſize is recommended, with his back broader than round: noſe large with wide noſtrils, cheſt deep and capacious, fillets great and high, haunches large, hams ſtraight, feet round, the ſole hard and dry, claws large, ears wide, thin, and more round than ſharp, eyes full, forehead prominent, and upper lips thick and deeper than the lower jaw.

Much may be ſaid for or againſt the ſeveral kinds of harriers, but to ſum up the whole conciſely, ſtaunch hounds of any ſort are deſirable; whoever has them of nearly equal age and ſpeed, with the further requiſites of packing and hunting well together, whether Southern, Northern, Foxſtrain, or Beagle, can boaſt an advantage in the diverſion, which few gentlemen (with every attention to their breed) ever attain, but at a great expence of both time and money.

As to the method of breeding hounds, too much care cannot be taken in the choice of the ſires from which the whelps are wanted; a very little inattention ſpoils the litter, which ſometimes proves degenerate, although from as high bred a dog and bitch as can be put together, and where every danger of a ſpurious croſs has been completely guarded againſt.

Young hounds ſhould be entered as near the time when they are a twelvemonth old as poſſible, and they ſhould be entered at the game they are deſigned to hunt, as moſt dogs prefer that game they were firſt blooded with, and encouraged to purſue. See *Hare* HUNTING.

2. The *grey-hound*, or *leporarius*, or *canis venaticus graius*, might deſerve the firſt place, on account of his ſwiftneſs, ſtrength, and ſagacity, in purſuing his game; ſuch being the nature of this dog, that he is ſpeedy and quick of foot to follow, fierce and ſtrong to overcome, yet ſilent, coming upon his prey unawares.

Dr. Caius derives the name of the *grey-hound*, or *gre-hound*, from its being the firſt in rank among dogs; and that it was formerly ſo eſteemed, appears from the foreſt-laws of king Canute, who enacted, that no one under the degree of a gentleman ſhould preſume to keep a grey-hound. The varieties of this ſpecies are the *Italian* grey-hound, which is ſmall and ſmooth, and the *Oriental*, which is tall and ſlender, with very pendulous ears, and very long hairs on the tail, hanging down a great length. There was formerly a variety, called the *Highland* grey-hound, which is now become very ſcarce, of a very great ſize, ſtrong, deep-cheſted, and covered with long and ſtrong hair. See DOG.

The make and proportions required in a good grey-hound, arrived at the age of two years, when he is full grown, are, that he have a fine ſkin, a body neither too long nor too great, ſtrong and pretty large, a long lean head, with a noſe ſharp from the eyes downwards, ſparkling eyes, with large eye-lids, a long neck, bending like a drake, and ſharp teeth, little ears, with thin griſtles in them, a ſtraight, broad, and ſtrong breaſt, a back ſtraight and ſquare with a riſing in the middle, his fore legs ſtraight and ſhort, his hind legs long and ſtraight, a round foot with large clefts, broad ſhoulders, round ribs, with a long ſpace between his hips, fleſhy buttocks, but not fat, and a long tail, ſtrong and full of ſinews. The old couplets that deſcribe this ſpecies of dogs were exact in the points they recommended, as neceſſary to form a complete grey-hound.

"Head like a *ſnake*,
Neck'd like a *drake*,
Back'd like a *beam*,
Sided like a *bream*,
Tailed like a *rat*,
And footed like a *cat*."

Of this kind, thoſe are always fitteſt to be choſen among the whelps that weigh lighteſt; for they will be ſooner at the game, and ſo hang upon it, hindering its ſwiftneſs, till the heavier and ſtrong *hounds* come in to offer their aſſiſtance; whence, beſides what has been already ſaid, it is requiſite for a grey-hound to have large ſides, and a broad midriff, that he may take his breath in and out the more eaſily; his belly ſhould alſo be ſmall, which otherwiſe would obſtruct the ſwiftneſs of his courſe; and his hairs thin and ſoft.

The huntſman is to lead theſe hounds on his left hand, if he be on foot; and on the right, if on horſeback. The beſt time to try and train them to the game, is at twelve months old, though ſome begin ſooner, and enter and try the females at ten months old, which laſt are ſaid to be generally more ſwift than the dogs; they ſhould be kept in a ſlip while abroad, till they ſee their courſe; neither ſhould you looſen a young dog till the game has been a conſiderable time on foot, he being apt, by over eagerneſs at the prey, to ſtrain his limbs.

The grey-hound is the beſt uſed in open countries where there is little covert; in theſe places there will ſometimes be a courſe after a hare of two miles or more, and both the dogs and the game in ſight all the while. It is generally ſuppoſed, that the grey-hound bitch will beat the dog in running; but this ſeems to be an error, for the dog is both longer made, and conſiderably ſtronger than the bitch of the ſame kind.

In the breeding of theſe dogs the bitch is principally to be regarded; for it is found by experience, that the beſt dog with a bad bitch, will not get ſo good puppies as an indifferent dog with a good bitch. The dog and bitch ſhould be as nearly as can be of the ſame age; and for the breeding of perfect and fine dogs, they ſhould not be more than four years old; an old bitch may be uſed with a young dog, but the puppies of a young bitch and an old dog will never be good for any thing.

The general food of a grey-hound ought to be chippings or raſpings of bread, with ſoft bones and griſtles; and theſe chippings ought always to be ſoaked in beef or mutton broth; and when it is nearly cool, ſome milk ſhould be added: this given the dog morning and evening will keep him in good heart and ſpirits; he muſt never have any hard bones given him, becauſe they harden his mouth, and hurt his teeth. If the dog grows ſick and weakly upon this diet, then take ſheep's heads with the wool on, waſh them clean, and boil them in a ſufficient quantity of water, to make a very rich and ſtrong broth, and add a large quantity of oat-meal to it. When the meat is very tender, and the broth rich, it is good and fit for the dog; and giving him ſometimes the one, and ſometimes the other, will very ſoon recover him. The kennel ſhould be airy, and the door towards the ſouth, the benches 2½ feet, with holes bored to carry off the urine; the ſtraw on the benches ſhould be frequently changed, and the kennel kept extremely clean. See KENNEL.

If one of theſe dogs is to run for a wager, or on any particular occaſion, he may be dieted with the following bread: take half a peck of good wheat, and the ſame quantity of the fineſt and drieſt oat-meal; grind theſe together, and let the meal be ſifted very fine; then add as much liquorice and aniſeeds, in powder, as will not give it too diſagreeable a flavour; and knead the whole into dough with the whites of eggs and new ale. This ſhould be baked in ſmall loaves conſiderably hard; and when the dog is to be fed with it, it is to be ſoaked in beef or other broth. He is to be led out to walk half an hour after ſun-riſe every morning, and half an hour before ſun-ſet every evening, and at his coming in fed with this ſoaked bread. The proper exerciſe for a grey-hound is the courſing him three times a week, and rewarding him with the blood of the hare, which will animate him in the higheſt degree, and encourage him to proſecute his game. But the hare alſo ſhould ever have fair play; ſhe ſhould have the law, as it is called, that is, have leave to run twelve ſcore yards before the dog is ſlipped at her, that he may have ſome difficulty in the courſe, and not pick up the game too eaſily. If he kill the hare he muſt never be ſuffered to tear her, but ſhe muſt be taken from him, his mouth cleaned of the wool, and the liver and lights given him by way of encouragement. Then he is to be led home, and his feet are to be waſhed with butter and beer, or rather with water and ſalt, and about an hour after he is to be fed. See ENTRANCE.

When the dog is to be taken out to courſe, he ſhould have nothing in the morning but a toaſt and butter, and then he is to be kennelled till taken out to the field. The kennelling of theſe dogs is of great uſe, always giving them ſpirit and nimbleneſs when they are let looſe; and the beſt way of managing a fine grey-hound is never to let him ſtir out of the kennel, except at the times of feeding, walking, or courſing.

With reſpect to the ſwiftneſs of the grey-hound, the following queſtions were ſubmitted to a gentleman, whoſe grey-hounds are known to be as ſwift as any in the kingdom. Whether the ſpeed of a grey-hound is equal to that of a firſt rate race horſe for the diſtance of a mile, or for a greater or a ſmaller diſtance? and, whether the ſpeed of any hare (ſuppoſing the dog and hare to be ſtarted without the law uſually allowed to the hare in courſing) is equal to that of the grey-hound, and to what diſtance, within that of a mile, the hare could exert that ſuperiority of ſpeed, ſuppoſing the hare to be the faſteſt animal of the two? His opinion was, that upon a flat, a firſt rate horſe would be ſuperior to the grey-hound, but in a hilly country, as in Wiltſhire, a good grey-hound would have the advantage; on the ſecond point, that although he had ſeen many hares go away from grey-hounds, laid cloſe in with them, without a turn, yet he believes a capital grey-hound (ſo laid in) would not ſuffer a hare to run from him without turning her. An incident, however, occurred in December 1800, which brought the ſpeed of the grey-hound and race horſe into competition. A match was to have been run over Doncaſter courſe for one hundred guineas, but one of the horſes having been drawn, a mare ſtarted alone to make good the bet, and after having gone the diſtance of about a mile, a grey-hound bitch ſtarted from the ſide of the courſe, and ran with her the other three miles, keeping nearly head to head, which produced a ſingular race, and when they arrived at the diſtance-poſt, five to four was betted on the grey-hound; when they came to the ſtand it was even betting. The mare won by about a head.

In February 1800, a brace of grey-hounds in Lincolnſhire ran a hare from her ſeat to where killed, a diſtance, meaſuring ſtraight, upwards of four miles, in twelve minutes; during the courſe there was a great number of turns, which very conſiderably increaſed the ſpace gone over; the hare ran herſelf dead before the grey-hounds touched her; this extenſive courſe, in ſo ſhort a time, is a ſtrong proof of the ſtrength and ſwiftneſs of the hare. Horſes have been as much diſtreſſed in keeping up for their riders to ſee a courſe, as in much longer chaces with hounds. The compiler (ſays Mr. Daniel) recollects a hare being found cloſe to the town of Bottiſham, in Cambridgeſhire, and which took away for the ſix mile bottom, twenty-two horſes ſtarted, but only one could make a gallop at the concluſion of the courſe; the hare (who was within fifty paces of the cover) was dead ſome yards before the grey-hounds, who were obliged to be held to recover them.

The remark made during his troubles, by the unfortunate Charles I. upon the grey-hound's affability, was juſt as applied to the animal, and a keen ſatire upon thoſe that ſurrounded him; a diſcourſe aroſe reſpecting what ſort of dogs deſerved pre-eminence, and every one allowed it to belong to the ſpaniel or the grey-hound. The monarch gave his opinion in the grey-hound's behalf, becauſe (ſaid he) it has all the good nature of the ſpaniel, without the *fawning*.

Many inſtances might be mentioned of the high ſpirit and courage, as well as uncommon ardour and velocity of grey-hounds. If it be aſked, what is allowed at the preſent day to be the beſt breed of them? The blood of the late lord Orford's dogs engrafted into thoſe of Wiltſhire and Yorkſhire has turned out the beſt grey-hounds. Allowing for ſome exceptions, it is generally imagined that grey-hounds croſſed from the fore-mentioned blood have proved themſelves ſuperior to others.

3. The *gaze-hound*, or *beagle*, is a dog more beholden to the ſharpneſs of his ſight, than his noſe or ſmelling; by virtue of which he makes excellent ſport with the deer and hare. He is alſo noted as exquiſite in chooſing of one that is not lank or lean, but full, fat, and round, which, if it happen to return, and be mingled again with the reſidue of the herd, he will ſoon ſpy out, and leave the reſt untouched, never ceaſing, after he has ſeparated it from its company, and till he has wearied it to death.

Theſe dogs were much uſed in the north of England, and on champain grounds rather than buſhy and woody places, and by horſemen more than footmen. If at any time he happen to take a wrong way, upon the uſual ſign made by his maſter, he immediately returns, takes the right and ready courſe, beginning his chace afreſh, with a clear voice, and ſwift foot, following the game with as much courage as at firſt.

This ſpecies, which was the *agaſæus* of Dr. Caius, ſays Mr. Pennant, is now loſt, or at leaſt unknown to us; and it is very different from the *agaſæus* of Oppian, which is our *beagle*, which ſee. See alſo DOG.

4. The *blood-hound*, or *canis ſagax* of Linnæus, differs nothing in quality from the *Scottiſh ſlut hound*, derived from the Saxon *ſlot*, the impreſſion which a deer leaves of its foot in the mire, and *hund*, a *dog*, ſaving that it is longer ſhaped, and not always of the ſame colour, but ſometimes red, ſanded, black, white-ſpotted, &c. though moſt commonly either brown or red.

Their nature is, that being ſet on by the voice and words of their leader, to caſt about for the ſitting of the preſent game, and having found it, they will never ceaſe purſuing it with full cry, till it be tired, without changing for any other.

They ſeldom bark, except in their chace, and are very obedient and attentive to the voice of their leader. Thoſe that are really good, when they have found the hare, make ſhow thereof to the huntſman by running more ſpeedily, and with geſture of head, eyes, ears, and tail, winding to the form or hare's muſe, never giving over proſecution, and running with a gallant noiſe.

They have good and hard feet, and ſtately ſtomachs, and are very properly denominated *ſanguinary* or *blood-hounds*, on account of their extraordinary ſcent; for if their game be only wounded, ſo that it eſcape the huntſman's hands, or if it be killed, and never ſo cleanly carried away, theſe dogs, by their exquiſite ſmell, will diſcover it, and not be wanting, either by nimbleneſs or greedineſs, to come at it, provided there be any ſtains of blood. Nay, though by all the cunning and foreſight imaginable, a beaſt be conveyed away without ſpot or blood, yet through the roughest and moſt crooked ways and meanders, this dog will find out the deer-ſtealer, and, even in the thickeſt throng, will, by his ſmell, ſeparate and pick him out.

The blood-hound was in great requeſt on the confines of England and Scotland, where the borderers were continually preying on the herds and flocks of their neighbours. The true blood-hound, ſays Mr. Pennant, was large, ſtrong, muſcular, broad-breaſted, of a ſtern countenance, of a deep tan-colour, and generally marked with a black ſpot above each eye. See DOG.

5. The *terrier*, or *tarrier*, only hunts the fox or badger; being thus called, becauſe after the manner of a ferret in ſearching for coneys he leaps into the ground, and affrights or attacks the beaſts, either tearing them in pieces, or haling them out by force; or, at leaſt, driving them out of their harbours to be taken in a net, or otherwiſe. See DOG.

The huntſmen have commonly a couple of terriers, that they may put in a freſh one, as occaſion ſerves, to relieve the other.

The time of entering the terrier is when he is near a twelvemonth old: if it be not done within that time, he will hardly be brought to take the earth. This entering and fleſhing of them may be performed ſeveral ways. Firſt when the foxes and badgers have young cubs, take an old terrier, ſet him into the ground, and when he begins to bay, hold the young one at the hole or mouth of the earth, that he may liſten and hear the old one's bay. The old fox or badger being taken, ſo that nothing remains within but the cubs, couple up the old ones, and put in the young in their ſteads, encouraging them by crying *to him, to him*. If they take any cub within, let them do with it what they liſt; not forgetting to give the old terriers their reward, which is blood and livers, fried with cheeſe, and ſome of their greaſe; ſhewing them alſo heads and ſkins to encourage them.

HOUND-*fiſh*, in *Ichthyology*, (ſee SQUALUS *muſtelus*,) the ſmooth hound-fiſh, or hound-ſhark.

HOUND *Point*, in *Geography*, a cape of Scotland in the Frith of Forth, and N. coaſt of the county of Linlithgow; ſeven miles W.N.W. of Leith.

HOUND'S *Tongue*, in *Botany*. See CYNOGLOSSUM.

HOUNDS, in a *Ship*, are thoſe parts of a maſt-head which gradually project on the right and left ſide, beyond the cylindrical or conical ſurface, which it preſerves from the partners upwards. The hounds, whoſe upper parts are alſo called cheeks, are uſed as ſhoulders to ſupport the frame of the top, together with the top-maſt and rigging of the lower maſt.
